Herbs in borders or beds should be carefully looked over and put in order. Old beds of Mint should be cleaned, and then a top-dressing of short, well-rotted manure applied. If fresh beds are to be made, it must be done at once. Lift the roots carefully, and plant them thinly in rows a foot apart in fairly rich soil, mulching them afterwards with short manure or leaf-mould. Thyme is best grown on

rather poor and dry soil, and a fresh supply of plants should be raised each year or two from seed. Sweet and Bush Basil must be sown thinly in pots or boxes under glass, and pricked off when large enough. Grow them for a time under the same conditions, but they may be put outside about the end of May or beginning of June. Seeds of any other annual or perennial herb may now be sown thinly in boxes, or in frames.

Lettuce.—The first sowing of Lettuce may be made now on a sheltered border, and an additional sowing every fortnight or three weeks during the spring and early summer months. One of the most useful varieties for early sowings is Tom Thumb, or Commodore Nutt. If these be thinned slightly in the seed-bed when large enough to handle, and the thinnings planted 3 or 4 inches apart, they will provide a useful succession before other varieties are ready. Plants that have been raised under glass, when thoroughly hardened, should be planted a foot apart each way on a sheltered border, taking care to remove a good ball of soil with each root. If this system be followed successfully, the plants will be fully as early and generally more satisfactory than autumn-sown produce.

Red Cabbage, &c.—If there are plants still in the autumn-sown seed-bed, plant a few of these at once in rich rotative soil. A pinch of seed may also be sown now, and the plants will provide useful little hearts in the autumn of better quality generally than those from older plants. A little seed should also be sown of Veitch's Self-protecting Autumn and Sutton's Michaelmas White Broccoli, and Chou de Burghley Cabbage.

THE HARDY FRUIT GARDEN.

By H. W. WADE, RAYLEIGH, ESSEX.

Transplanting Young Gooseberry and Currant Bushes.—The rooted cuttings of Gooseberries and Currants of the autumn of 1895, in order to afford more space for branch development, may at this season be dug up and planted at wide distances apart, taking care that their labels do not get detached in doing the work. Before proceeding to plant them, remove any roots which proceed from the stems, preserving only those at the bottom, which should be cut back 1 or 2 inches of the point from which they start. This shortening of the roots will result in the growth of numerous fibrous roots. If the piece of ground to which the plants are going to be removed is in need of enrichment, a good dressing of decayed manure from a spent hot-bed or the rubbish heap should be dug in. Plant in rows at 15 inches asunder each way, the planting and digging being carried on simultaneously, the workman keeping a good wide trench open all the time. In planting, the workman should take hold of the stem and shake the plant in an upward direction, so that the soil may trickle among the roots, the latter being brought within about 3 inches of the surface after the soil has been broken up and levelled. Thus treated, and assuming that the buds on the lower half of the cuttings were rubbed off when the cutting was made, nice short-stemmed bushes not liable to throw up suckers will be easily secured. If standards—that is, bushes having clean straight stems of 2 to 4 feet in height—are desired, those of the young plants with the most promising central shoots should be chosen, and the shoot tied to a stick of sufficient strength and length to maintain it, and the subsequent growth of shoots in position till the desired height is reached, when the shoot should be topped. The treatment consists of cutting out all other shoots, so as to throw the energies of the plant into the lengthened stems, and with that object all buds should be rubbed off for the entire length of the stem, with the exception of four towards the top. These buds, following the beheading of the several shoots, will speedily push into growth, and the young shoots thus made should not be interfered with before pruning-time next spring, when they should be cut back to within three buds of their bases. The unbury-headed specimens, planted by the side of walks between the ordinary bushes, at 10 to 12 feet apart, have a telling effect, and afford examples of the ornamental and the useful combined. Each standard should be affixed a stake for support. [These standards, being more liable to be acted upon by the wind than the short-stemmed bushes, will in the course of a few seasons require the support of a stout fencing wire hoop to which their chief branches may be secured, the hoop or hoops being kept in place by fastening them to three or four net stakes. Ed.]

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction in these pages, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, MAR. 23.—Royal Hort. Soc. Coms.
SATURDAY, MAR. 27.—Royal Botanic Soc. Meet.

SALES.

		Tuberose, Camas, Spiras, Green-house Plants, Carnations, Roses, &c., at Protheroe & Morris' Rooms.
MONDAY,	MAR. 22	Special Sale of Hardy Perennials and Bulbs, Roses, Lilies, Shrubs, &c., at Stevens' Rooms.
TUESDAY,	MAR. 23	Imported and Established Orchids, at Protheroe & Morris' Rooms.
		Japanese Lilies, Palms, Seeds, Herbaceous Plants, Azaleas, Begonias, &c., at Protheroe & Morris' Rooms.
WEDNESDAY,	MAR. 24	A splendid Collection of about 5000 Roses, Shrubs, Palms, Azaleas, Border Plants, &c., at Stevens' Rooms.
THURSDAY,	MAR. 25	Border Plants, Roses, Bulbs, Shrubs, Lilliums, &c., at Stevens' Rooms.
FRIDAY,	MAR. 26	Imported and Established Orchids, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ENSUING WEEK, deduced from Observations of Forty-three years, at Chiswick.—43° 9'.

ACTUAL TEMPERATURES:—

LONDON.—March 17: Max., 53°; Min., 44°
PROVINCES.—March 17 (6 P.M.): Max., 51°, York, London; Min., 42°, Sumburgh Head.

It is not easy to write when a friend and associate of thirty years' standing is taken from us, but on this occasion we feel that the whole horticultural fraternity shares in our regrets. The author of the encyclopædic "Fruit Manual" has left a claim which posterity will not be slow to recognise. But to us, writing in the present, it is the personal element which is most prominent; and, in our case, that takes date from the ever-memorable year, 1866. In that year was held the greatest and most notable of the International Horticultural Exhibitions and Botanical Congresses; and Dr. Hogg was one of the foremost in the organisation of that great undertaking. But Dr. Hogg's earlier history is very interesting from its associations, on which account we may take the opportunity to reprint, with a few necessary modifications, what we said on a former occasion:—

"To most horticulturists at all conversant with the doings of the Royal Horticultural Society, the main facts of Dr. Hogg's later career are tolerably well known. As one of the Editors of the "Journal of Horticulture," in conjunction with the late Mr. JOHNSON, the veteran historian of British gardening; and latterly as sole editor; as the author of the standard descriptive work on pomology ("The Fruit Manual") and of numerous other serviceable publications, he became known to a wider circle. From his connection with the Pomological Society, as well as with the Royal Horticultural Society, and specially with its Fruit Committee, Dr. Hogg was brought into contact more or less directly with the great body of British horticulturists, and

his sterling qualities of head and heart secured for him the cordial esteem and good will of his fellow workers.

He was born in 1818, his father having been the head of the well-known firm of Hogg & Wood, of Coldstream.

At an early age, Dr. Hogg exhibited a taste for the study of natural science, and especially of botany. The love of these studies induced him first of all to direct his attention to the medical profession, but his short experience of the dissecting-room, and the prospective drudgery of the general practitioner, operated as a deterrent to any great progress in that direction; still, those branches of science which were not strictly medical continued to be the subjects which more immediately engrossed his attention, botany being always the means by which he hoped to attain distinction. After pursuing his "humanities" at the University of Edinburgh, Dr. Hogg acquired a knowledge of practical horticulture at the establishment of Messrs. LAWSON, of that city, and subsequently at that of Mr. RONALDS, of Brentford. Here the taste for pomology showed itself, and here, in particular, were the foundations laid of that interest in, and knowledge of, the subject which afterwards proved to be the most important features in Dr. Hogg's public career. The intercourse with RONALDS, at that time engaged in the publication of the magnificent "Pyrus Malus Brentfordensis," gave the impetus to that study which may be said to have become the most absorbing pursuit of his life.

After remaining for some time at Brentford, Dr. HOGG proceeded to France, stopping for a short time at Rouen, where the fruit garden was then under the management of the well-known DUBREUIL, and which still remains a monument of that pomologist's skill and sagacity. From Rouen, the subject of our notice made his way to Paris, where he completed his botanical studies under A. L. DE JUSSIEU, MIRBEL, and other celebrities of the Jardin des Plantes. Remaining in Paris for some time, he afterwards proceeded to Germany, and passed some time at Bonn. On his return to this country, finding that science held out but little encouragement in the shape of substantial reward, Dr. HOGG turned his attention more particularly to the more remunerative field of practical horticulture, on which he brought to bear the knowledge of botany and vegetable physiology which he had acquired during his pupilage. It was about this period that he became associated with the management of what, a century and a half previously, EVELYN had termed "that great undertaking of Brompton Park." This was an immense fruit tree nursery at Brompton, extending from Brompton Church almost to Gloucester Road, Kensington, on the one side, and from Kensington Road to Brompton on the other, thus including the site of the former garden of the Royal Horticultural Society, at what is now called South Kensington.

This nursery was founded in 1681 by LUKAR, FIELD, COOKE, and LONDON; and it may interest many of our readers to know that LUKAR was gardener to the Queen Dowager at Somerset House in the Strand; FIELD acted in the same capacity to the Earl of BEDFORD at Bedford House, also in the Strand; COOKE held a similar situation with the Earl of ESSEX of Cashobury; and LONDON was the fitting servant and friend of Bishop COMPTON at Fulham Palace, while he was also the grandfather of the first Lord SELSEY. The fortunes

of the "great undertaking of Brompton Park," after flourishing for a century and a half, were however, when Dr. HOGG joined the copartnership, in 1845, of Gray, Adams & Hogg, on the wane. These with whom he was associated were either enfeebled by age or by want of means, or both, and he soon found himself saddled with responsibilities he had no inclination to sustain, and consequently he retired after a few years, and from that time to the present has devoted himself to the literature of horticulture. The advantages of a practical kind which he derived from his connection with "the great undertaking" were, however, of great value. It was during that time that the first form of the "Fruit Manual" appeared. It still remains the text-book of pomologists and nurserymen, and it was not till after its publication that nurserymen adopted the plan of issuing descriptive catalogues of fruits. The "Fruit Manual," the last edition of which was published in 1884, is the best and the most generally known of Dr. HOGG's separate publications; but it was not the first in order of time of his literary productions, for while still a youth he published in Edinburgh a "Treatise on Annuals," with descriptions of those cultivated at that time, and he subsequently issued a "Treatise on the Dahlia, its History and Cultivation," and retained to the last a liking for florists' flowers, especially Tulips.

About 1844 Dr. HOGG commenced a work entitled "British Pomology," but the only portion ever published was the first volume, treating on the Apple. At the time this was published the present rage for the study and cultivation of fruits did not exist. No bookseller would take the responsibility of its publication, and he had to undertake it himself. As a remunerative speculation it was a failure, and, like LINDLEY'S "Guide to the Orchard and Kitchen Garden," published twenty years previously, it was still in advance of the time. Now, we believe, the work is entirely out of print. Not discouraged by the failure of this attempt to excite public interest in pomology, Dr. HOGG adopted other means of keeping the subject before the public mind. Early in 1853 we find him writing as follows:—

There is, perhaps, no country in the world where the study, and consequently the cultivation, of fruits is more neglected than in our own. In America, they have in various States pomological 'societies' and 'institutes,' which meet as regularly as our Royal and Linnean Societies, and discuss pomological subjects. Several excellent works have issued from the press of that country, and are justly popular, and it is to America that we are indebted for some of our finest varieties of fruits. In Germany, too, it is a very popular study, of which the numerous pomological societies and publications furnish ample evidence. In France it has a great measure of support, although perhaps not so great as in those countries already mentioned, but certainly far greater than in our own; and in Belgium it is found not unworthy of Government patronage and support. Need it be wondered, then, that so little is known when so little interest is manifested on the subject in this country? We trust the time is coming when the same vitality and energy will be exhibited as there was at the time when Mr. KNIGHT and Mr. SABINE devoted so much of their attention to it.

And the time speedily came, for in little more than twelve months after this was written, the British Pomological Society was instituted (in 1854), with Sir JOSEPH PAXTON as president, and Dr. HOGG and Mr. SPENCER as joint secretaries, the initiative having been taken by Mr. SPENCER of Bowood, Mr. RIVERS of Sawbridgeworth, and Dr. HOGG. After several years of useful-

THE LATE ROBERT HOGG, LL.D.

(See page 188.)

ness, and after passing through the vicissitudes which appear to be normal phenomena in the career of societies as well as in that of most individuals, the British Pomological Society was merged in the Fruit Committee of the Horticultural Society, the first meeting of which body was held at the rooms of the Horticultural Society at 21, Regent Street, on July 5, 1858. Subsequently, Dr. Hogg was secretary to the Fruit Committee, and afterwards he took an active part in the practical business of the Royal Horticultural Society, acting as one of the directors (in conjunction with Rev. Mr. BERKELEY and Mr. MOORE) of the Society's garden at Chiswick. In this latter capacity it fell to Dr. Hogg's lot to superintend the replanting of the fruit garden, and to select the varieties to be retained in the diminished space then available for the purpose.

Dr. Hogg's name must also be honourably associated with those who by their zeal and energy promoted the success of the London International Horticultural Exhibition and Botanical Congress of 1866. The management of the great banquet at the Guildhall, which has had few if any rivals since, falling to his share; while to the last he remained one of the trustees of the Lindley Library itself, a tangible memorial of the Botanical Congress. It was, therefore, a happy coincidence that Dr. Hogg should have been one of those who represented this country at the International Horticultural Exhibition at St. Petersburg, on which occasion he became the recipient of a handsome slab of malachite as a mark of the Emperor's recognition of British Horticulture and of courtesy towards its representatives. Dr. Hogg and the present writer represented this country at the Florence Congress in 1874.

Laterly it became obvious that the labourer's work was done. He resigned the editorship of the *Journal* to his son, his attendances at the Royal Horticultural Society's meetings became less regular, and on the 14th inst. the end came quietly and peacefully.

ROYAL HORTICULTURAL SOCIETY.—The next Fruit and Floral Meeting of the Royal Horticultural Society will be held on Tuesday, March 23, in the Drill Hall, James Street, Victoria Street, Westminster, 1 to 5 P.M. A lecture on "Bad Transference and its Effects on Fruit" will be given at 3 o'clock by the Rev. GORDON SALMON, M.A.

ROBBERY AT THE OFFICES OF THE ROYAL HORTICULTURAL SOCIETY.—An inpatient robbery was perpetrated at the Royal Horticultural Society on Thursday, March 11. The precincts of the Royal Horticultural Society's Council Room were invaded by a thief, who quietly and expeditiously appropriated the overcoat of the Assistant-Secretary, Mr. J. WEATHERS. The latter was on the other side of the dividing-curtain, but heard nothing. The thief was considerate enough to leave behind a bundle of papers which he took from one of the pockets. In view of the possibility of a thief making off with some of the most valuable books from the Lindley Library, which finds a home in the Council Room, and the loss of which, unlike that of Mr. WEATHERS' coat, might be simply irreparable, some means ought forthwith to be found to render the access of a thief to this room much more difficult of accomplishment than it is.

ROSE SHOW FIXTURES FOR 1897.—The following dates of Rose shows are kindly furnished by Mr. E. MABLEY, viz., June 17, Thursday, Colchester and Ryde; June 23, Wednesday, Portsmouth (N.R.S.); June 26, Saturday, Windsor; June 29, Tuesday, Canterbury, Sutton, and Westminster (R.H.S.); June 30, Wednesday, Croydon; July 2, Friday, Crystal Palace (N.R.S.); July 7, Wednesday, Glasgow and Reigate;

July 8, Thursday, Bath, Gloucester, and Woodbridge; July 15, Thursday, Norwich (N.R.S.), and Helensburgh July 22, Thursday, Halifax and Treatham July 27, Tuesday, Tisbury. Our correspondent states that these are the only dates definitely fixed that have as yet reached him, but others will reach him about the middle of the month of April, which will be published in due course in these columns.

HORTICULTURAL CLUB.—The usual monthly dinner and *conversazione* took place at the rooms of the Club, Hotel Windsor, Victoria Street, Westminster, S.W., on Tuesday evening March 9. The chair was to have been taken by Sir J. D. T. LLEWELLYN, Bart., but business at the House of Commons prevented him from attending. Mr. SALMON, Clerk of the Gardeners' Company, was requested to take his place, and in a few appropriate words he thanked the members for the honour they had done him, the youngest member of the Club, in placing him in so honourable a position. There were also present Messrs. Geo. Paul, F. Rochford, James Walker, J. Assbee, T. Francis Rivers, F. Rivers, jun., C. E. Reasson, G. Bunyard, James H. Veitch, and the Secretary. A paper was read by Mr. T. Francis Rivers, entitled "Notes on Fruit," which displayed an intimate knowledge of the whole subject, especially the raising of new varieties of fruit. This paper we hope to give in a future issue. It was followed by a very interesting discussion, in which most of the members present took part. Mr. G. Mount, of Canterbury, contributed to the decoration of the table with some of the magnificent Roses which he exhibited at the Drill Hall, and which won such general admiration, and for which a vote of thanks was recorded to him by the committee.

BOTANIC GARDEN, ST. PETERSBURG.—Dr. FISCHER von WALDEHEIM has been appointed successor to the late Professor BATALEIN in the Directorate of the Imperial Botanic Garden.

GEORGES VILLE, the eminent chemist, attached to the Museum d'Histoire Naturelle, died on the 22nd ult. in his 74th year.

HUNTS COUNTY COUNCIL.—Mr. D. T. FISHER has just completed a course of lectures on "Cottage and Allotment Gardening" in various districts of Huntingdonshire. The subjects of the lectures were as follows:—First lecture, "How to make Dead Soils Live and Grow Good Crops. The Draining, Trenching, Digging, Enriching, and Clearing of the Earth." Second lecture, "Potatoes for the Home, the Market, the Million; Onions and other Root-crops." Third lecture, "Apples, Bush-fruits, and Strawberries, &c."

THE EXECUTIVE COMMITTEE OF THE INTERNATIONAL HORTICULTURAL EXHIBITION OF 1866.—The death of Dr. Hogg, on the 11th inst., lessens by one the surviving members of the Executive Committee of the International Horticultural Exhibition and Botanical Congress of 1866—perhaps the chief horticultural event in Her Majesty's long reign. Looking at Heath's photograph of the Executive Committee taken in 1866, we note that the survivors now form a comparatively small minority. They are Sir Daniel Cooper, Bart., Treasurer; Messrs. W. Bull, Edward Easton, John Lee, W. Paul, H. J. Veitch, Dr. Masters, Congress Secretary, and Richard Dean, the Assistant-Secretary. The Executive Committee originally consisted of twenty-one persons, including Mr. Dean, twenty-two. Dr. Berthold Seemann, the original Congress Secretary, went abroad, resigning the secretaryship, and was succeeded by Dr. M. T. Masters, but his name was retained on the committee. The Deputy-Chairman, Mr. J. J. Blandy, never, it is believed, saw the exhibition, and he died before the report was issued. Those who went down to The Star and Garter Hotel at Richmond to dine at the conclusion of the labours of the committee were twenty-one in number, including Mr. Charles Lee, who rendered valuable services in laying out the exhibition ground in conjunction with Mr. John Gibson, Mr. George Eyles, and Mr. Harry J. Veitch. The absentees were Mr. J. J. Blandy, Mr. J. Fleming, and Dr. See-

mann. To the best of our knowledge, Mr. Edw. and Easton, the civil engineer, still survives. Of the 110 jurors who made the awards on that occasion, probably not more than twenty survive. Of the speakers at the banquet at the Guildhall of the city of London, which was presided over by the father of the present Lord Mayor, only Sir Daniel Cooper remains; and of the six members of the Common Council of the City, who had so much to do with the arrangement of the banquet, not one survives.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held on Monday, March 22, when a paper will be read by Mr. C. H. HOOGER (Fellow), entitled "Fruit-growing as an Auxiliary to Agriculture." The chair to be taken at 8 o'clock.

SOCIETY OF JERSEY GARDENERS.—A monthly meeting was held in the Lyric Hall, Jersey, on Thursday evening, March 11, there being a large attendance of members present. Mr. H. J. SKINGLEY, gardener to CHAS. GODFREY, Esq., read a paper upon "Ferns," in which he offered valuable remarks upon the propagation and treatment of Ferns in general. Mr. P. BOIS made a few remarks on variation in Ferns, and a good discussion followed. Various Certificates and other awards were made to interesting exhibits.

CAPE FRUIT.—The ss. *Tantallon Castle* has arrived from the Cape with 728 cases of fruit, consigned as follows:—292 cases of Grapes, to Mr. HUDSON; 195 cases do., to the Colonial Consignments and Distributing Company (Ltd.); 5 cases to W. R. SUTTON & Co.; 56 do., and 29 cases of Peas, to Messrs. WOODHEAD, PLANT & Co.; 129 cases of Grapes to Mr. E. HUDSON; and 109 cases do., to Mr. NATHAN. This entire consignment arrived in very good condition.

RENFREWSHIRE GARDENERS' SOCIETY.—The concluding fortnightly meeting for this session was held on the 10th inst. Mr. MORTON ROSSHALL read an excellent paper on the "Rock Garden," in which he described the principal effects to be secured in the formation of such a garden, and a list of plants most suitable for planting was included. Mr. MAXWELL BALSTON afterwards gave a paper on "The Rose: its history and culture." The part of this paper dealing with the history of the Rose was much appreciated, and the cultural details in connection with both papers were discussed by the members present.

READING GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.—An interesting paper upon "Table Decorations" was read by Mr. POWELL, of Park Place Gardens, Henley-on-Thames, before the members of this body on Monday evening, March 15, in the Club Room, British Workman. Mr. C. B. STEVENS, the President, presided over a large gathering of members. A very interesting discussion took place, in which Messrs. NEVE, TURTON, STANTON, MARTIN, WOODFORD LEES, DEARLOVE, TUNBRIDGE, CHAMBERLAIN and FRY took part.

CARDIFF GARDENERS' ASSOCIATION.—The usual fortnightly meeting was held in the Reference Room of the Cardiff Free Library, on the 9th inst. The Society met by the invitation of Mr. BALLANER, the librarian, to examine the collection of books on gardening and allied subjects contained in the reference library. In giving his welcome to the association, Mr. BALLANER intimated his willingness to add any work on horticulture which the Society might propose as desirable to make the collection a more complete one. A short address was given on gardening literature by the vice-president, after which the books were examined by the members.

A FLOWER SHOW IN INDIA.—The annual Flower Show of the Agri-Horticultural Society of India was held in the society's garden at Alipore, a suburb of Calcutta, on Feb. 19 and 20. Considering the deficient rainfall, there was a much better display of fruit and vegetables than had been anticipated. It proved that the soil of the plains of India is capable of producing much more than is generally believed, even in

a bad season, providing water can be obtained, and good cultivation is given. The plant classes were contested by some of the leading Calcutta nurserymen, and the groups staged for effect were very good. The feature of the show was the flowering annuals, which made a very fine display, the best being *Asters*, *Petunias*, *Verbenas*, and *Phlox Drummondii*. Some fine plants of *Cissampelos Dampieri* were shown, in 10 and 12-inch pots. They appeared to be potted very lightly, in a compost of leaf mould, cow-manure, and a little loam. Honorary exhibits were sent from the Royal Botanic Garden, Seebore, from Baboo Lalal Dhilli Choud; and from the Maharajah's garden, Durbungah, the two first exhibits contained some rare and valuable plants, and the Durbungah exhibit was an excellent miscellaneous collection of fruits, flowers, and vegetables.

NEWCASTLE AND DISTRICT HORTICULTURAL IMPROVEMENT SOCIETY.—The monthly meeting was held on Tuesday, March 9, when Mr. JOHN BULLOCK presided over a good attendance of members. Among the flowers exhibited were *Orchids* and *Hyacinths* by Mr. LAWSON, gardener at Heathdale, Gosforth; and a collection of *Dendrobiums* by Mr. MURRAY, the gardener at Oakwood. Mr. W. H. LEONARD read a paper on the "Chemical Composition of Roots, Vegetables, Seeds and Fruits." The paper included tables showing the constituents of each of the different parts of plants. A lively discussion was afterwards engaged in.

PRESENTATION.—On the occasion of his leaving the gardens of Lord PALMOUTH at Moreworth Castle, after thirteen years' service, Mr. H. MARKHAM was the recipient of a beautiful ink-stand, with suitable inscription engraved thereon, presented by the young men employed in the garden, and a silver-mounted biscuit-box from his lordship's servants. Mr. MARKHAM had to leave Moreworth owing to the continued ill-health of himself, his wife, and family, induced by the damp, relaxing air of the place. We hope that he will soon meet with an appointment commensurate with his abilities as a gardener.

SHIRLEY AND SURROUNDING DISTRICT GARDENERS' AND AMATEURS' MUTUAL IMPROVEMENT ASSOCIATION. The annual general meeting was held at the Parish Room, Shirley, Southampton, on the 15th inst., there being a good attendance, the chair being occupied by the Vice-President, W. F. MAYOSS, Esq. The report showed the Society to have had 140 members, to have held thirteen meetings during the year, at which the average attendance was forty two. The statement of accounts showed a small balance in favour of the association. The President, W. F. G. SPRINGER, Esq., C.C., and the Hon. Sec., H. J. HOBBS, were re-elected, and also an enlarged committee of fifteen, instead of nine, as formerly. Mr. A. DEAN, Lecturer in Horticulture to the Surrey County Council, gave a brief but interesting address on "Horticultural Progress during the Victorian Era."

DEVON AND EXETER GARDENERS' ASSOCIATION, CINERARIAS AND PRIMULAS.—At the fortnightly meeting on March 3, Mr. J. WEEKS, gardener to Mr. E. A. SANDERS, Stoke House, Exeter, read an instructive and carefully prepared paper on *Cinerarias* and *Primulas*. Mr. H. WEBBER occupied the chair. The papers dealt pretty fully with the history of the plants, and the cultural details furnished were very good. In the case of the *Cineraria*, both single-flowered and double-flowered varieties were dealt with; the same also as regarded the *Primula*, although in the case of this plant hardy species were reviewed, and their culture touched upon.

M. G. BONNIER has been elected a member of the Botanical section of the Académie des Sciences (Institut de France).

STOCK-TAKING: FEBRUARY.—As was to be expected, the very unsettled political outlook has been one means of raising the imports of the past month from £35,476,736 in February, 1896, to

£27,245,164 for the month just ended—an increase amounting to £1,768,423. From the "summary" table of the Returns for February we take the following figures:—

IMPORTS.	1896.	1897.	Difference.
	£	£	
Total value ...	35,476,736	37,245,164	+1,768,423
(A) Articles of food and drink, duty free ...	11,490,928	11,860,774	+439,811
(B) Articles of food and drink, dutiable ...	1,749,632	2,127,945	+378,313
Raw materials for textile manufactures ...	7,317,791	8,691,585	+1,373,794
Raw materials for sundry industries and manufactures ...	2,746,438	2,795,651	+49,223
(A.) Miscellaneous articles ...	1,125,915	1,139,623	+13,708
(B.) Parcel Post ...	13,433	98,743	+4,810

We may note here that the increase on the two months, as compared with January and February of last year, amounts to £3,270,241. As for food imports in the month just closed, Wheat shows an increase of 1,393,689 cwt.; in Wheat-meal and flour, 123,369 cwt.; Barley has decreased by 329,190 cwt.; Oats have gone down by 190,680 cwt.; Indian corn, however, has gone up 110,080 cwt.; Indian corn-meal having an increase of 36,600 cwt.; Tea shows the large increase of 3,093,212 pounds; unmanufactured tobacco has gone up by 1,529,769 lb.; while unmanufactured shows a falling off to the amount of 75,688 lb. Sugar shows a falling off in both refined and candied, to the extent of 337,875 cwt.; unrefined having gone down by 1,070,812 cwt.—all as compared with February, 1896. There is a great increase in the supply of raw materials for textile manufactures, the whole increase being £773,794. The figures relating to the imports of fruit, &c., are given in the subjoined table:—

IMPORTS.	1896.	1897.	Difference.
Fruits, raw:—			
Apples ... bushel	308,864	623,265	+439,401
Cherries
Plums	719	369	-359
Pears	1,399	3,117	+1,718
Grapes	1,446	1,405	-41
Unenumerated	39,975	39,397	-578
Onions	451,098	552,119	+101,021
Potatoes ... cwt	39,980	40,790	+810
Vegetables, raw, unenumerated ... value	£12,713	£68,514	+4,100

From the Cape, with other products, have come splendid looking samples of Oranges—beautiful without, but (judging from those purchased by the writer at 4s. a-piece), very deceitful as to flesh and flavour. To come to—

EXPORTS,

but little surprise need be felt at the falling off shown in the total—£1,839,413. Considering the state of things in the near East, and in India—famine and disease, but little wonder need be expressed. The loss for the two months of the year now belonging to the past is placed in the Board of Trade Returns at £3,199,663; but it is satisfactory to note that matters in the United States look promising, and point to a further and not far distant revival of trade in several branches—a consummation devoutly to be wished.

ISLE OF WIGHT HORTICULTURAL IMPROVEMENT ASSOCIATION.—The monthly meeting of this Association was held at Warburton's Hotel, Newport, on Saturday, March 6, when there was a good gathering of members, who were present to hear a paper read on Winter Vegetables, by Mr. W. TARBURCK, F.R.H.S., gardener to Sir CHARLES SEELEY, Bart., Brooke House. Dr. J. GARVES, B.A., J.P., chairman of the Association, presided, and made a few appropriate remarks expressing regret that the essayist, through ill-health, was not able to read his paper. A dish of

excellent tubers of *Stachys tuberosa* was shown by Mr. W. E. WICKENS, gardener to R. R. PITTS, Esq., J.P., C.C., Longy House, Newport. Mr. J. J. LINSING obtained a Certificate for a collection of *Cyclamen Charming Bride*, two-year old corms. Several new members were elected.

AN INSTITUTE FOR THE TEACHING OF BOTANY.—Mr. MARTINDALE is advocating the establishment, in the Royal Botanic Garden, Regent's Park, of an institute for botanical teaching in London. Since botany ceased to be a necessary subject in the curriculum in the medical schools, there has been a deficiency in our teaching establishments, those few that do exist turning their attention almost exclusively to biological and physiological botany. Years ago we used to lament the too exclusive attention paid to morphology and the systematic botany of flowering plants; but now all that is changed, the pendulum has swung in the opposite direction, and the highly trained microscopists often come up for examination very poorly equipped with a knowledge of plants and their natural orders. This is a distinct misfortune to medical men, travellers, horticulturists, and others connected with economic botany. If the Royal Botanic can justify its title by the establishment of a school for educational purposes, and for research, we shall be disposed to look more leniently on its extraneous frivolities.

ANTHURIUM SCHERZERIANUM.—A First class Certificate has been awarded by the Société Nationale d'Horticulture d'France to a variety called *Le Géant*, and a First-class Award for a group of seedlings, all raised by M. A. de la DEYSSASSE of Angers. These are all variations from one species.

KEW.—His Majesty the King of the BELGIANS paid a visit to the Royal Gardens during the past week.

TULIP FROM CHITRAL.—We understand that the Tulip which we recently figured (January 30) was collected at Chitral by Surgeon-Lieutenant A. F. STEVENS, I.M.S., and was presented by him to the Agricultural and Horticultural Society of India.

LAPAGERIA ROSEA IN THE OPEN AIR.—A Devonshire correspondent, writing in reference to the paragraph on this subject which appeared in our last issue, p. 171, says that Mr. ROBIN'S garden lies in a coolish snath of the Haldon Hills, and quite two miles from the sea. The plants are growing on a western aspect. Both *L.*, and its variety *alba*, are not uncommon in Devonshire and Cornwall, flowering with merely slight protection against severe weather.

MINIATURE CHRYSANTHEMUMS.—M. ANATOLE CORDONNIER contributes to the *Revue Horticole* for March 1 the following letter on these dwarf plants:—"The miniature Chrysanthemums which I showed last year in Paris at the Exhibition of the French National Horticultural Society were growing in pots from 2 to 3 inches in size at most, and bore each a single flower from 5 to 6 inches across. They were raised in the following way:—About August 15, cuttings with a crown-bud "taken" a few days previously from plants in pots or in the open air were placed in pots of 3 cent. (about 1 in.) across. The pots were filled with compost mixed with "Papillon" manure during the winter, to which a large proportion (about a third) of sand was added. These pots were sunk in an hot-bed, and kept shaded for three weeks under a clove lid glass. At the end of the time the little plants showed roots; they were then re-potted into 2 to 3-inch pots, and the plants kept in a cool-house, where they flowered naturally. These little plants in small ornamental pots, and mixed with Ferns, make a charming and a lasting decoration, requiring no other care than occasional watering."

PUBLICATIONS RECEIVED.—*Country Life* (20, Tavistock Street), a weekly journal, profusely illustrated, and interesting to all fond of rural work, sports, or recreation.—*The Navy and Army* (HUDSON G. KEARNS, London, S.E., and GEORGE NEWNS, 10, Southampton Street), a fortnightly publication, edited

by Commander CHAS. N. ROBINSON, R.N. The letter-press deals with such subjects as the title of the newspaper suggests, and the illustrations are good and numerous.—*Nature Notes* (London: JOHN BALL & SONS), edited by JAMES BRITTON, F.L.S., continues its valuable work in connection with the Selborne Society.—*The European Mail* (Imperial Buildings, Ludgate Circus, E.C.). A useful paper to send to absent friends.—*Bulletino della R. Società Toscana di Orticultura*, February.—*Pharmaceutical Journal*, March 6.—*Favourite Flowers of Garden and Greenhouse*, vol. iii, No. 29.—*The Summary of a Meteorological Journal* kept by C. L. PRINCE, at his Observatory, Crowborough Hill, Sussex.—*Schedules of Prizes, National Rose Society*, for Exhibitions at Portsmouth, June 23; at the Crystal Palace, Sydenham, July 2, and at Carrow Priory, Norwich, July 15.—*The Botanical Gazette* (Chicago), February.—*Garden and Forest* (New York), February 24 and March 3.—*The Florists' Exchange* (New York), February 27.—*The National Nurseryman* (Rochester, N. Y.), March.—*The American Florist* (Chicago and New York), February 27.—*Mechanics' Monthly*, March.—*The Canadian Horticulturist*, published by the Ontario Fruit Growers' Association, February.—*Catalogue of Duplicate Specimens in the Billoware Herbarium* (N. Carolina, U.S.A.).—*The Botanical Magazine* (Tokyo), January 29.—*Müller's Deutsche Gärtnerei-Zeitung*, March 10.—*Botanische Jahrbücher für Systematik, Pflanzengeschichte und Pflanzengeographie*, von A. ENGELM (Leipzig), February 23.—*Illustrirte Flora* (Wien), March 1.—*Botanisches Centralblatt*, Band lxi., No. 10.—*Gartenflora* (Berlin), March 1.—*Wiener Illustrirte Garten-Zeitung*, February.—*Le Jardin*, March 5.—*Annales Agronomiques*, February 25.—*L'Amylotopus*, un nouveau genre de Myxomycètes, par E. ROZE (Extrait du Journal de Botanique, December 16, 1896).—*Nouvelles Observations sur les Bactériacées de la Pomme de Terre*, par M. E. ROZE, and *La Maladie de la Gale de la Pomme de Terre*, par M. E. ROZE (Extraits du Bulletin de la Société Mycologique de France).—*Revue Diplomatique et Coloniale*, 1re Année, No. 1, March 1 (Paris).—*Association Française pour l'Avancement des Sciences* (Paris), M. E. ROZE, sur deux plantes tunisiennes du XVI. Siècle.—*Le Chrysanthème*, Journal de la Société Française des Chrysanthémistes (Lyon), March 5.—*The Dublin*, by various writers (MACMILLAN & Co.).—W. WESLEY, *Catalogue of Botanical Books*, 28, Essex Street, Strand; 3000 numbers, comprehensive, accurate, and well arranged.—*Moniteur Horticole Belye*.—*Nord Horticole*.—*Ferns and Fern Culture* (J. BIRKENHEAD, Sale).

the perianth segments are cut to the base; in structure it comes near to *Scilla bifolia*. *Geo. Nicholson, Royal Gardens, Kew.*

species is worthy of cultivation. The lorate foliage is stiff and notched at the apex; the flower racemes are erect, and carry a number of pale yellow flowers, the great attraction being the purple-coloured crest of the lip which gives them a distinct character. The species is plentifully distributed in India and Ceylon, and it is usually grown in this country under the name of *Aërides Wightianum*. The plant is figured in the *Botanical Magazine*, t. 5138.

Sarcobolium bellinum.—Plants of this free flowering species are to be seen in the Orchid-house. It is a small plant of compact habit, with small leaves, 6 inches or more in length, and carrying short peduncles furnished with a few of the pretty blooms, the petals and sepals of which are of a pale yellow colour with deep brown blotches, which almost cover the ground colour. The labellum is white with a hairy look, and has a blotch of yellow in the centre. This is an early flowerer, introduced through Messrs. Low & Co., from Burmah, in 1884. *R. L. H.*

HOME CORRESPONDENCE.

ENDIVE.—That Endive is an old inhabitant of our gardens there can be no doubt. A native of the East Indies, it has found its way into many countries, and in France it is largely grown and eaten, boiled, and in various ways as salad. In this country, as Mr. Henri de Vilmorin has pointed out, we make no such good use of Endive as a boiled vegetable, as the French do. The precise time when it was introduced to this country is not exactly known. Suffice it to say, that it formed one of the items of a bill-of-fare in the reign of Queen Elizabeth; and Gerard's instructions as to its management does not materially differ from the practice of modern cultivators of the plant. Its ancient popularity was doubtless enhanced by its being esteemed one of the best antidotes to scurvy. This at the time the plant was introduced to this country was, no doubt, a more formidable disease than now, and from coming into use in winter, when salt meat formed a much greater proportion of the general food than it does at present, Endive, no doubt, as well as other plants of its class, speedily became a favourite; at all events, we may reasonably infer that its property of checking a disease so much dreaded at the time led to the plant being welcomed to the gardens of all types are cultivated in gardens in this country, distinct enough in appearance to be regarded as species, but yet doubtless derived from a common origin—one is the curled form, the other the broad, flat-leaved, known as the Batavian; and there are various forms of both, but more of the curled than the broad-leaved is probably the normal form. The curled varieties are selections from it, and in taking on their curled and handsome cut-leaved character, they have, it is likely, lost some of their original hardiness from the autumn and early winter, and the varieties of the Batavian type for general autumn and early winter work. A fact supporting the view of a common origin is, that the seeds are alike in all respects. Except in market gardens and those of the wealthy, Endive is rarely found; it has never held the popular taste as the Lettuce has. Endive can be found but in very few allotments and cottage gardens, though a good deal of attention is given to summer salad; yet a dish of well-blanching Endive, set round with slices of highly-coloured Beet, is an ornament to the table, to say the least of it. Some of the French selections of the green curled are extremely handsome; the leaves, in some cases delicately and exquisitely cut, and lines of some of these alternating with those of the green and white Batavian types, would prove attractive, and furnish borders usually empty in winter. *R. D.* [For how long? Ed.]

THE CARDOON AS A DECORATIVE PLANT.—Several kinds of vegetable are utilised for decoration, whether in beds during the summer, in vases or baskets; such are red foliaged Beetroots, curled Kales, &c. The favour of the Cardoon does not please everybody, and in this case it would be preferable to grow the plant as a garden ornament. I have seen this done, and the effect was excellent, indeed as good as that obtained from *Fernduana cinnerea*, *Aralia papyrifera*, *Wigandia caracasana*, or other foliage plants employed in the

CHIONOSCILLA ALLENI.

The first mention of this name I can find is in a letter from Mr. James Allen, Park House, Shepton Mallet, to Mr. J. G. Baker. The latter gentleman has kindly allowed me to copy the following extracts:—"I think I mentioned to you a year or two since that I have found a good many natural hybrids of *Scilla bifolia* and *Chionodoxa Lucilie* come up in my garden. Both of these species seed very freely with me, and are getting quite a nuisance, as they crowd everything out. These hybrids I have named *Chionoscilla*, and when they get into strong plants, I think the best of them will be great favourites. . . . I send you flowers of some of these, and I think you will at once see that they are intermediate in their character. These seedlings bear seed freely, and the seedlings of the second generation are apt to revert to one or other of the original parents." The letter from which I have quoted, is dated March 2, 1893; a previous one, dated April 3, 1889, gives particulars of these accidental crosses. There are dried specimens in the Kew Herbarium from Mr. Allen, and also from Rev. Wolley Dod. The specimen here figured flowered in the Rockery at Kew, amongst a lot of *Chionodoxa* received from Mr. Whittall, Smyrna; and in all probability we received the bulb from him. A glance at the illustration (fig. 57) will show what a handsome garden plant it is. The colour and general aspect are that of a good *Chionodoxa Lucilie*, but

FIG. 57.—CHIONOSCILLA ALLENI.

SCOTLAND.

NOTES FROM EDINBURGH ROYAL BOTANICAL GARDEN.

Vanda parviflora.—Although it can hardly be called a showy Orchid, yet, on account of its remarkable colouring, and the time at which it flowers, this

garden. Careless plant singly on the grass or in groups, especially the variety with prickly foliage (also the best for culinary purposes) have a picturesque effect. Seeds of the de Tours variety should be sown in a hot-bed-frame in February or March, and the seeds should be new in order that the seedlings may be vigorous, and not inclined to throw flowers. The seeds may be sown on the soil in the frame or three in a thumb-pot; the latter method being preferred, the tubers and liking to be "tricked out" owing to their possessing a tap-root. When the three young plants are well developed the strongest should be chosen, and the others destroyed. Until the middle of May they should be carefully repotted, and special attention paid to affording water in order to prevent any check to growth. A large hole is made and filled with well-manured soil, and as soon as the weather permits it the plants are transplanted to the spot. A mulch of farmyard-manure should be placed around each plant, and copious waterings afforded to aid development, remembering that the more luxuriant the plants the less likelihood that they will flower, and thus spoil their decorative aspect. Well protected against frost with straw coverings, or removed bodily to a cellar, such plants are quite tender and fit for cooking. *Louis Gentil, Ken.*

FARFUGIUM GRANDE.—In a cottage window in Hyde I noticed a grand specimen of the old neglected *Farfugium grande*, a good old plant for decorative purposes. In the same window a plant of *Primula obconica* seemed to be quite at home, the same was edged up with sticks and string; this attracted my attention, and I was bold enough to make inquiries. This was the information gained of the lady who evidently had liked after the window decoration, "Law bless me, sir, it is a beautiful plant, but don't you know, sir, it is an awful poisonous plant; my sons say it gives you a rash if you are not careful, so I protect my children from it in the way you see." *Rusticus.*

A SIMPLE FUNERAL-WREATH.—I wanted a wreath to place on a lamented friend's grave, and I desired it made of his favourite flowers, combined with some leaves; which, it seemed to me, would, together, convey to those who knew him and me, and were aware of our long-time friendship, something like the thoughts I wished to express. I wrote to my friend, Mr. W. Spinks (Messrs. Hewitt & Co's Nursery, Solihull), stating what I desired. This is what I received: a wreath of very moderate size, composed of bunches of home-grown Lilies of the Valley, and deliciously-perfumed purple Violets in alternation; the leaves of the Lilies and (here and there) small sprays of Bay-leaves being the only greenery used. The bunches of flowers were tied very loosely, so as to avoid any appearance of formality; and the result was so charmingly effective, that I venture to pen these lines in the hope that they may not be without their use. The flowers chosen were, as indicated above, my departed friend's special favourites; and the combination was intended to convey in the language of flowers suggestions of (symbolically) the sweetness of disposition and vernal character of the departed one, and my own affectionate regard for him; while, by the bay-leaves, I sought to typify my friend's chief characteristic—the conscientious doing of everything he undertook throughout the thirty years I lived in daily intercourse with him, and the victory he won in the battle of life. *Edward W. Badger, Birmingham.*

PLANTING POTATOS.—In many gardens it is a common practice to plant Potatoes at a given date regardless of the situation or nature of the soil. In low-lying places, or on stiff soil, it is prudent to plant late, late frosts being more injurious in such than on higher ground. With properly prepared sets the shoots soon show through the soil, and if very early planted on stiff land, the latter becomes hard before the shoots find their way through it, the consequence being spindly growth. Better by far allow the sets to remain unplanted till the middle or end of the month of April, when the elements will have reduced the crust to a good fifth. The depth at which the sets should be placed depends on the variety, and the space required by the tops. When Potatoes are grown as a field-crop, 27 inches is the usual distance for all varieties between the rows, though some would give better crops if more space was allowed. With close rows, there is less soil available for earthing-up, and many tubers get exposed, whereas, when the rows are wider apart, there is more soil. In gardens the rows should be wider than 27 inches, and

the sets in the rows more apart. The smaller distance suits *Asheaf*, *Walnut-leaf*, and other small-haulm varieties; but mid and late-season varieties should have much more. On stiff land, shallow planting is best. Blanks are frequently seen in Potato-fields owing to the sets failing to grow, and sometimes the haulm is very weak. This misfortune is due largely to lack of care in selecting the sets, or from planting sets that are quite dormant; but if planting be done in the middle of April, unsuitable sets would be detected, and cast on one side. Potato sets that are allowed to sprout to a great length in the clamps, and the longer sprouts are removed at planting time cannot make a second strong growth, hence a comparative failure of the crop in some instances. The gardener with his small area to plant, should be enabled to have well-prepared sets of all the varieties he grows, and failure, except from the ravages of disease, should be unknown to him. Some gardeners inter-crop, but it is not a practice to be encouraged, it being better to have one good crop than two poor ones, but want of space compels many a man to adopt it. Those Potatoes which readily admit of inter-cropping are the short-topped ones. When Broccoli, Kale, Savoys, &c., are planted between rows of Potatoes, the space between the rows ought not to be less than 3 feet. Tubers of mid and late season varieties intended solely for planting purposes in the garden should be grown, if possible, in a bed, this affording the necessary change of soil; moreover, they can remain in the soil till perfectly mature, which could scarcely be carried out if the Potato-land were inter-cropped with other plants that might need mounding up before the crop was ripe for lifting. *H. C. Prinsp.*

DIFFERENCES IN PRUNING ROSES. I have lately been enabled to inspect Roses in places situated 200 to 300 miles apart. Two points greatly attracted my notice. The first was the present promising state of the plants everywhere, and the second their semi-uniform state of growth. Taking the last first, it is surprising how slightly distance modifies times and seasons of growth between widely-separated localities. The whole of the wide area of Scotland and England, as represented by actual growths, made up to the middle of March, 1897, may be found between one inch and two inches high. And the most puzzling part of the problem lies in the fact, that the longest growths are by no means always found furthest south. Doubtless local circumstances of shelter, soil, &c., largely determine the inception and progress of growth. But then the environments of Roses are conspicuously local, almost erratic, rather than geographical, or affairs of altitude, latitude, and longitude. Hence the latest Roses I have seen this March have been those growing in or near London. But every now and again we are surprised by sudden development of growth, and equal abnormal conditions of dormancy within short distance of their opposites. Doubtless many of these departures as to times and conditions of growth are the results of soil, site, culture, and especially seasons of planting and pruning, and ratio of vitality. The whole subject is of especial interest to the rosarian, in as well as of great importance to the gardener, inasmuch as the later the spring growths of Roses, in reason, the safer the buds, and the more perfect the blossoms. We owe the promising state of our Roses this March to the mildness of the winter. So far, hardly a Rose anywhere has been crippled by the severity of the winter. Even searching in March winds, unless at the time of the late severe storm, which was destructive through its sheer force rather than its cold, have always been wholly absent; and unless March, which hardly came in like a lamb, goes out like a very fierce lion indeed, it is not likely to deal very harshly with our Roses. In that hope, pruning and pegging-down are operations which are proceeding in all directions. Earlier pruning than there used to be is also another prominent sign of the times. In the choice between a loss of force and sap through the conversion of buds into food for late frosts, and the sacrifice of force through bleeding resulting from late pruning, more rosarians now prefer the former to the latter risk. The wholesale pegging-down of perpetuals and Teas is also becoming more popular, and deservedly so, day by day. *D. T. F.*

HYBRID FUCHSIA.—I send some flowering shoots of a Fuchsia raised from seed obtained by crossing an ordinary greenhouse variety with *F. splendens*, the latter being the seed parent. The plant has been continuously in flower since August last, although only growing in a 6-inch pot, and now carries 147

blossoms in various stages of development. During the shortest days of winter it was very beautiful. *South Devon.* [A very fine flowering and elegant form; quite an acquisition. The flowers are pendulous, their colour is rosy-red, the tips of the sepals greenish. *Ed.J*]

FRUIT NOTES FROM BARHAM COURT.

An hour spent in the fruit room at Barham Court in company with Mr. Woodward affords an amount of interest seldom enjoyed elsewhere. The number of little-known varieties of Apples and Pears that are remarked is noteworthy. On the occasion of a visit, several good varieties of Pears and Apples were noted which had kept in first-rate condition. One of these was *Pear Passe Crassane*, a variety which was never very good at Mereworth Castle. In some places this Pear is only fit to eat after an unusually warm season, but at Barham it is seldom that it is not good. The fruit noted were large, some of them weighing 12 to 14 oz., and flesh melting and flavour excellent. Dr. Hogg, in his *Fruit Manual*, remarks that at Teddington the variety was useless, as is also the case in many other places.

Olivier de Serres is another first-rate late Pear, which is in season after that nice fruit *Josephine de Malines* is past its best. The variety keeps sound when carefully stored in a suitable fruit-room—say, one having an average temperature of 40°, and in which the air is slightly moist; a common fault of fruit-rooms, especially those built above the ground, is that they are too dry. In a dry room the fruit, instead of keeping plump and fresh-looking, shrivels. Those persons who like a somewhat crisp, piquant-flavoured Pear, should grow this variety, affording the tree a good position, and keeping the roots near the surface of the ground, so that the fruits may mature well.

Nouvelle Fulvie is a Pear which has very juicy pulp, fine in texture, and sweet. The fruit keeps sound till February, and in some years rather later. Like most good Pears, the tree should be planted in a warm position, and in the land is heavy and cold, and the latitude northerly, it should be given a good place on an east or west wall.

Josephine de Malines is one of our best Pears, and the fruits are of good dessert size. When properly ripened in a warm room, the flesh, which is of a salmon colour, becomes very melting. It is at its best in January, although it will keep till the end of February. *H. Markham.*

BERLIN.

A GENERAL horticultural exhibition will be held here from April 25 to May 9, to celebrate the 75th anniversary of the Horticultural Society of Prussia. This exhibition will be still larger than the noted one held in 1890. Over 11,000 square metres are already occupied, that is 4000 metres more than in 1890. The large chemistry-hall in the park of Treptow, in which the Industrial Exhibition took place last year, will be transformed into a large Rose-garden, where more than 900 metres of Roses will be seen. Artificial rocks will be decorated with *Rhododendrons*, &c.; and a waterfall will be illuminated by electric light in various colours. The building in which last year the Fisheries Exhibition was held will contain instead of the aquariums seven dioramas, and also rocks and grottos; in short, all will be enlarged. But strange to say, up till now there are not many Orchids entered, although the 1st prize for 100 plants is 1000 marks (£50), offered by the city of Berlin. English Orchid-growers would probably be successful if they would send their plants; out-flowers would also be welcome. As to Cyclamens and other plants there will be great competition, and it would be highly interesting to German gardeners to compare the English strains with their own. Address for the Programme and Schedule to the Secretary-General, Berlin, N., Invalidenstrasse 42.

CULTURAL MEMORANDA.

ADIANTUM CUNEATUM.

It is time to make preparations for the repotting of *Adiantums*, and at the same time the stock may be increased by the division of any plants that have become larger in size than is convenient. Prepare, in the first instance, a sufficient quantity of compost, taking care that it is sweet, porous, and moderately dry. In preference to the use of a great quantity of peat, I recommend a freer use of light fibrous loam, somewhat half-decayed leaves, also peat broken roughly, and sufficient charcoal and sand to prevent stagnation and sourness. A water-logged or sour soil is inimical to most Ferns. The soil should be made moderately warm before potting, and all the necessary pots made scrupulously clean, and carefully drained by pebbles. Shake a good portion of the old soil from the roots and pot firmly, just slightly covering the young crowns. For some time afterwards the greatest care will be necessary in watering the plants, it being most easy to give more than is required. When the roots have penetrated the new soil, the supply of water may be gradually increased with advantage. Neglect in regard to the immediate application of water when necessary is sure to be attended by failure. Subsequently a little soot or liquid-manure may be added to the water occasionally, but soot-water should be clear. The common species, as *A. cuneatum*, will start freely in a temperature of 55° by night, and such a degree of heat is most conducive to a sturdy useful growth. Slugs and various insects are very injurious to the young and tender fronds, and must be sought for and destroyed. Young plants may be raised easily from spores, and in private gardens there are usually plenty of seedlings from self-sown spores. If these be taken up carefully and potted, and placed in a warm corner near the glass, they will quickly grow into nice serviceable plants. *H. Markham.*

EUPHORBIA (POINSETTIA) PULCHERRIMA.

As this plant seems to be creating some interest lately, I venture to mention a simple method of culture which answers well in the southern counties. The method also has the advantage of saving labour, as the plants practically require little or no attention for several months of the year. (See fig. 58.)

After flowering, the plants are kept dry until about May, and then cut back. When they have started into growth, say about June, they are planted out in the beds in the pits, which previously had done duty for forcing Potatoes, &c. After the *Euphorbias* have taken root in the bed, they are frequently exposed to the elements. I find that by the middle of August they have made fine strong cuttings, which, when rooted and grown on, frequently give bracts quite 18 inches across.

EUPHORBIA JACQUINLEFLORA.

This is a lovely winter-blooming plant to grow in pots to furnish sprays for decorative purposes. The cuttings may be taken at the end of June or the beginning of July. Pretty good plants can be had by striking as late as the beginning of August. The cuttings may be placed in a hotbed, and after rooting, potted off, with a subsequent shift into 4 or 5 inch pots, and grown on in an intermediate temperature with plenty of light, especially towards the flowering period. With the above treatment we have measured sprays of flowers 19 inches in length, and I have no doubt larger sprays could be had with better treatment than ours usually have.

After the flowers have expanded they will stand for a couple of months in a conservatory with an average temperature of 45° to 50°. The sprays have a very pleasing effect amongst other plants. Of course, anyone requiring a larger quantity of smaller sprays for cutting would be inclined to start earlier in the season, and plant out, besides pinching the shoots occasionally. [In order to secure fine effects with plants in pots, some gardeners strike eight to ten cuttings in a 18-size, and repot without separating them. Ed.] *James Baer, Boldre Grange Gardens, Lymington.*

GESNERA GERMINA.

This lovely old *Gesnera* is one of the most useful plants I know of for winter-stove decoration, but it has the good property of blooming at almost any desired season. The present month is a very suitable time to shake the tubers out of the spent soil, and start them for coming into flower in the winter. Place the tubers rather thickly on the surface of well-drained pots or pans, filled to within 3 inches of the rim with any light kind of peaty soil and sand, from which it will be easy to separate the roots without injury later on, and cover them to the depth of about 2 inches. Afford a gentle watering, and place the pans in a temperature of 65° or 70°. No more water must be afforded than will preserve the soil in a moist state; and as soon as the plants are 1 to 2 inches high, they should be separated and potted, the number of plants going in a pot being a matter of choice and convenience. If fine specimens are wanted, one tuber in a pot only should be set. The plants should be stopped when about 4 inches high, or let alone in this respect. Gardeners usually put five plants in a flower-pot of 8 inches diameter, which suffice to make an effective mass. After potting, keep the atmosphere close and moist, but afford very little water until the roots start into growth. When potted off from the pans, they should be placed at least 1 inch deeper than before; for the reason, that they throw out the greater part of their true roots near the surface, and

FIG. 58.—FRUIT AND SECTION OF EUPHORBIA (POINSETTIA) PULCHERRIMA.

it is by means of these roots that nourishment is chiefly obtained. The plants should be kept close to the glass during the summer months, but it will be necessary to shade them during bright sunshine, and the atmosphere should be maintained in a thoroughly moist state; but this must not be effected by excluding air or using heavy shading, otherwise the plants will assume a sickly and drawn appearance, and the foliage lose its colour and mottled beauty; moreover, they must not be syringed, as to do so spoils the beauty and freshness of the leaves. The chief enemy to this *Gesnera* is the mealy-bug. If there is one about the place, it is sure to get on this plant. *Edward Bennett, Queen's Road, Epsom.*

NOTICES OF BOOKS.

AN ILLUSTRATED FLORA OF THE NORTHERN UNITED STATES, CANADA, AND THE BRITISH POSSESSIONS. . . . by N. L. Britton, Ph.D., and Hon. Addison Brown. . . . Three Vols. Vol. I. (New York: Charles Scribner's Sons. Imp. 8vo, pp. 612.)

This is the first instalment of a work that will be valuable to botanists, and to growers of hardy herbaceous plants and shrubs, so many of which came originally from the area comprehended in this volume. It is a book on the plan of *Bentham's* (illustrated) *Herbbook to the British Flora*. The arrangement of the orders is in conformity with that of Engler. Lindley's proposal to end all ordinal names in *aceae* is followed, for which we may be thankful. The descriptions are accurate, concise, and clear, the illustrations helpful; there are more than

1400 of them in this one volume, and it is intended that every plant mentioned shall be thus illustrated. Of course, the woodcuts are small, but they are clear, and, what is of great importance, the proportionate size is given, so that although the illustrations are in almost all cases considerably reduced, yet the actual size of the plant can be easily ascertained. As in "*Bentham's*," tabular keys are given which are useful, but often not free from pitfalls for the unwary. The system of nomenclature adopted is what may be termed the Neo-American, in which an exaggerated respect for certain so-called "laws," but which are merely arbitrary devices to secure the greatest facilities to the student in his speaking or writing of particular plants, occasionally leads to great confusion, and breaks the very important rule that forbids us to attribute to any author anything that he has not said. As the synonymy is duly attended to, and a full index given, the inconvenience from these changes in nomenclature is lessened, but still in such matters we prefer equity to law. The book is a very valuable addition to the garden library.

LE CHRYSANTHÈME A LA GRANDE FLEUR. By Anatole Cordonnier. (Published by the Author, Baillet, Nord, France.)

We noticed this work about a year ago, when it was first published, and are not surprised to find that a second edition has been called for. In style and get-up generally the new issue, considering the low price at which it is published (2fr. 50c.), leaves little or nothing to be desired; and, in addition to the cultural matter contained in the work as originally noticed, we find that the author has increased the size to about 200 pages, and added further explanatory illustrations.

So comprehensive is the scope, that M. Cordonnier's book must be pronounced at once one of the most entertaining and useful manuals that have appeared on the subject of *Chrysanthemum* cultivation. It is divided into four parts, the first of which deals with cultivation in its various phases, from the cutting to the blooming plant; the second is devoted to a useful list of selected varieties for various purposes, with descriptions and a note as to the best bud to be taken; the third part deals with a variety of subjects interesting to his readers; and the concluding portion is in the form of a monthly cultural calendar.

M. Cordonnier is an able exponent of the art which be teaches, and a prominent exhibitor at most of the leading continental shows; he is also secretary of the Northern French *Chrysanthemum* Society, and therefore writes with authority.

English readers who understand French will find *Le Chrysanthème a la Grande Fleur* worthy of perusal, and should not fail to place it on their shelves for future reference, although, of course, it must be understood that it is intended primarily for continental growers. An important feature of the book is the indication of the proper bud to be taken in the case of many of the varieties described in the selected lists.

ORCHID NOTES FROM KEW.

EUPHORBIA ELIZABETHLE.—An example of this orchid, which has thriven unusually since its introduction from Madagascar in 1892, is now in flower at Kew. Last year the plant matured two new pseudo-bulbs, which are *Onion-like*, purplish, about 1 inch in diameter, and bear four leaves each, the terminal one of which is 3 feet 9 inches long and 2 inches wide. The flower-spikes grow out at right angles, two from the base of each new pseudo-bulb, and from opposite points. The spikes are 1 foot long, and bear in the aggregate sixty-four flowers and buds, the strongest spike showing twenty-three. A second plant has developed three spikes, one of which bears about thirty flowers and buds. The plants are grown in pure sphagnum in 5 inch teak baskets suspended from the roof over a water-tank in a hot, moist house. Whilst growing they are kept saturated at the root. In the same house is a plant of the newly imported, and most remarkable-looking *E. Petersiana*, which seems

to be in a state of suspended animation. Has anyone succeeded in getting a plant of this Orchid to start?

Aerides Vandarum is now in flower in the cool Orchard-house, where it has grown vigorously since its removal, some five years ago, from the tropical-house to a shaded position along with *Odontoglossums*. It now covers a large slab of tree-fern stem covered with sphagnum-moss, in which its thick, wrinkled, grey roots evidently like to ramble. The subulate leaves are fully 8 inches long, and of a healthy dark-green hue. There are eight flowers open upon the plant, all excepting two being solitary, on short slender stalks; they are pure white, 2 inches in width, and the segments are waved and toothed in the most extraordinary manner. This species first flowered in this country in 1857, when it was figured in the *Botanical Magazine* as *A. cylindricum* (t. 4982). It is a native of the Sikkim Himalaya and Khasia at 5000 feet elevation, "hence it is a sub-tropical plant, a circumstance of which cultivators should take note." (Veitch).

Phaiolopsis Bosalli.—A plant of this rare little species, received from the Calcutta Botanic Gardens two years ago as *P. Parishii*, is now in flower. On the plant flowering, Mr. Rolfe at once recognised it as *P. Bosalli*. When described by Reichenbach in the *Gardeners' Chronicle*, 1883, xix., 274, from specimens introduced by Messrs. H. Low & Co., it was said to be a native of the Philippines; but this is now known to be a mistake, this species having since been several times collected in Burma. It has ovate oblong green leaves, a short stoutish peduncle, bearing when strong as many as twelve flowers; the Kew plant, being small, has, however, only three flowers. The sepals are lanceolate, 1 in. in length; the petals shorter, bright yellow, barred and blotched with dull brown; the lip is whitish, short, curiously bent back, with a pair of car-like lobes, and an erect purple bristle on the crest. Its nearest ally is *P. cornu-cervi*. A figure of it has been prepared for the *Botanical Magazine*.

Cycnocheilus Lankiviesii.—Two *p* plants of this handsome Orchid, both males, are now in flower in the Kew collection. They were received last year from Demerara, where this species is indigenous, and they have grown vigorously all the winter in a hot, moist house. The strongest of the new pseudo-bulbs, which average eight inches in length, carries a spike of flowers, each four inches across, in colour dull yellowish green, heavily mottled with brownish-purple; the narrow, oblong, fleshy lip is white and yellow, with a few conspicuous red spots. The column is 3 inches long, slender, very gracefully curved, and of a purple colour, except at the apex, where it is thicker and mottled with green. The raceme springs from the axil of a leaf near the apex of the pseudo-bulb, and is horizontal rather than pendulous. The leaves are falcate, plicate, 9 inches long, 1½ inch broad, and six or eight grow on each pseudo-bulb. During the growth of the flower buds there is a copious secretion of nectar at the base of the pedicels, and behind the brown linear bracts which subtend each pedicel.

Arpophyllum medianum is a Reichenbachian species discovered in Guatemala by Herr Wendland, to whom Kew is indebted for the example now flowering in the cool Orchard-house. It is similar to *A. giganteum* in habit, and has a dense erect spike of flowers 6 inches long, the colour being two shades of bright rose-purple.

Lelia glauca, better known perhaps as *Brassavola*, is now common in collections, but we do not often see so good a variety of it as is now in flower at Kew. It has four flowers, each 4 inches across, with broad regular segments, and a large well-formed lip, coloured creamy white with a conspicuous blotch of purple on the disc. There is also a plant in flower of the common form.

Bulbophyllum barbigerum is now in flower, the plant has increased fourfold since Sir Trevor Lawrence shared with Kew his only example five years ago. It now has pseudo-bulbs 1 inch in diameter, leaves 2 inches long, with two flower-spikes each 6 inches long, and bearing a dozen of its singular hairy versatile flowers. II. II.

SOCIETIES.

ROYAL HORTICULTURAL Scientific Committee.

MARCH 9.—Present: Dr. M. T. Masters (in the chair); Mr. McLachlan, Mr. Michael, Rev. W. Wilks, Prof. M. Ward, Dr. Müller, Mr. J. T. Bonnet-Poë, Mr. Douglas, and Rev. G. Henslow (Hon. Secs.).

Beetles with Grapes.—Mr. McLachlan had received some small beetles found about the roots of Vines, about a quarter of an inch long, with a blunt thorax and rather sluggish in manner. They proved to be *Triox subulbosus*, and were introduced in the crushed bones used for mixture. Not being vegetable feeders they do no harm to the Vines. The best trap would be a dried rabbit skin with the inner side downwards.

Larvæ of Daddy Longlegs.—He also received a sample of propagating soil in which Iceland Poppies were grown, abounding with the caterpillars of this fly. Bisulphide of carbon, cyanide of potassium (1 to 1 per cent. solution in water), or to remove the soil and burn it, were methods recommended in such cases.

Apple Root with Adventitious Buds.—Dr. H. Müller exhibited a specimen, thickly covered in places with innumerable buds, usually known as "Burr Knot." The original cause is obscure, but Dr. Masters observed that such roots are often cut up and used for propagating.

Gynicathy, etc., with Root Failure.—A collection of bulbous plants were received from Mr. W. C. Atkinson of Aigburgh, Liverpool, in which the roots had been very imperfectly developed, but then arrested and decayed. Mr. Douglas undertook to investigate the case, Dr. Masters observing that the bulbs might not have been properly ripened before lifting.

Drift Wood from Arctic Seas.—Dr. M. T. Masters exhibited specimens of wood obtained by Mr. Fisher. They had apparently travelled from Siberia to Frenz Joseph Land, and consisted probably of the Siberian *Prunus Cembra* (dwarf form), Willow, Elm, &c.

EDINBURGH BOTANICAL.

MARCH 11.—The members of the above Society held their monthly meeting at 5, St. Andrew Square, Edinburgh, on the above date, Dr. A. P. ALLEN in the chair. The private business consisted chiefly of the Treasurer's statement of accounts for the session 1895-96, which was found to be satisfactory.

The next item of public business consisted of a paper "On the Photo-Micrography of Organic Structures, Recent and Fossil," read by R. A. BOBROWSON, Esq., M.A., B.Sc., of St. Andrew's; and some excellent specimens of photographs of sections of wood and fossil trees were exhibited. After a little discussion as to the manner of using the apparatus, the reader was awarded a vote of thanks for his paper.

The report of the excursion of the Scottish Alpine Botanical Club to Clova in 1896 was read by Dr. W. CRAIG.

In the meteorological observations for February, taken at the Royal Botanical Garden, and read by Mr. A. D. RICHARDSON, the following items were noted: Barometer: highest reading 30.55 inches at 9 p.m. on the 13th; lowest 29.256 inches at 9 a.m. on the 2nd; mean 29.851, being 1.50 above the average. Shade thermometers: highest 66° 2' on the 26th; lowest 25° 2' on the 12th; frost occurred on three days. Radiation thermometers: highest in sun 101° 0' on the 23rd; lowest on grass 17° 0' on the 17th; frost occurred on grass on eight days. Sunshine: total for month 428 hours; sunniest day the 27th, with 5 hours; being 64.4 per cent. of the possible amount; sunless days 10. Rainfall: total for month 1.790 inch, being 0.781 inch below the average; greatest fall in twenty-four hours 0.515 inch on 23th; rainy days, fourteen.

TRURO DAFFODILS.

MARCH 16, 17.—The exhibition of Daffodils and other spring flowers held at Truro on the above dates must have filled Cornwall with enthusiasm for these early-flowering plants. It was certainly one of the best collections of Daffodils that has been staged by any society in England for some time, and great credit is due to the officers for the zeal they have manifested.

The principal winner in Barr's competition was Miss CURRY, of Lisnore, Ireland, who had a collection of fifty varieties, including some remarkably showy and distinct flowers. Lady M. BOSWICK was the good 2nd. In all, there were about fifty varieties of Daffodils only.

Rev. G. H. ENGLEHEART, of Appleshaw Vicarage, Andover, acted as judge, and he had difficult work, as the specimens were exceptionally uniform in quality.

In the classes for spring bulbs and early herbaceous plants there was also good competition.

Rhododendrons were a special feature, and an attractive exhibit came from D. H. SULLIVAN, Esq., Truro, who was 1st; T. HUGHES, Esq., 2nd. They were all grown out doors, and showed how much earlier these plants bloom in Cornwall

than in most parts of England. Cavellias from the open were also very fine, for a collection of which T. HUGHES, Esq., St. Austell, was 1st.

Messrs. BARR & SONS, Covent Garden, contributed a splendid collection of their well known Daffodils and other spring flowers.

Mr. T. S. WAKE sent a good collection of Daffodils, Anemones, and Primulas.

Messrs. J. JAMES & SONS, of Farnham Royal, Slough, sent some beautiful specimens of their strain of *Cicneraria*.

MANCHESTER ROYAL BOTANIC.

MARCH 16, 17.—Under rather favourable auspices as regarded weather, the show in the Town Hall, Manchester, presented a brilliant aspect. The Hippocreatums from Messrs. Ker, Liverpool, were gorgeous, and the Orchids, both for quantity, and in the quality of the plants, greatly exceeded any previous spring show. The earlier breeds of Cattleyas were splendidly in evidence, and with *Musevellias*, *Odontoglossums*, and *Cypripediums*, formed an interesting display. Many novelties were presented, but the judges, taking a leaf out of the Instructions of the Council of the Royal Horticultural Society, were inexorable in keeping down the number of the awards, so that those made at this show, which counts for something, particularly in regard to the cultivation of Orchids, may be looked upon as well bestowed.

The chief honors, with Gold Medal, fell to ELIJAH ASHWORTH, Esq., Hurefield House, Wulmslow, and we do not know, if we take the twenty-five feet of frontage table which two gardeners—the brothers Holbrook—put up, if ever Mr. Ashworth exhibited from his rich store a better lot. His Cattleyas formed a particularly rich group. His Cattleya Trianae Normanni was a marvel of brilliancy, quite equaling Mr. BULL'S *C. hildae*, of similar colour, that took a First-class Certificate at the Royal Horticultural Society's meeting at the Hill Hotel last autumn. Another with amethyst-colored segments and of close fold in motion, with a lip forming a great circle with the lower lobe of intense crimson, lacked up with prominent orange to fill up under the column was noted. There were one or two others which received an Award of Merit, but really, there were so many select varieties here, that it must have been difficult to pass them by. The varieties of *C. Trianae* also were fine flowers.

Another plant, still unacquainted, *O. splendensimum* grandiflorum with numerous spikes of very high coloured flowers, was remarked. D. S. LEECHMAN was also noteworthy, and D. noble nobilis (but not the giant Mr. ASHWORTH used to show) was prominent. A pretty, classic looking *Dendrobium* with fine flowers, and of a form, the whiteness very pronounced, and possessing a deep roseate coloured eye. D. Wardium and D. crassinode were fine flowers; and there was a fairly good *O. Schneiderianum*. The pretty *Odontoglossum nevium* (now) was in the flower—it is a plant too seldom, and well worth a look. There were also good *O. crispum* and *O. Anderssonianum*. *Cypripediums* were represented in numbers. *C. Rothschildianum* being very fine; and one *P* that still holds its own as a distinct and much valued species, viz. *C. × oleum* with its fine ruby-colored lines on the dorsal sepal, and a purple and white result. In all, the plants of the party worthy goods obtained by the cross-breeder. The whole of the plants were nicely put up among a variety of greenery.

A. WARBURTON, Esq., Vine House, Haslingdean (Mr. Jno. Lofthouse, gr.), made his first effort as an Orchid exhibitor, at Manchester, and his collection was at least as good as it was elsewhere. The three *Odontoglossum* which have been so much in evidence here and at Ghent were here again, viz. Ann Charles, a full square flower, of exquisite spotting of a ruby tint, and with segments almost overlapping, received a First-class Certificate. This variety is sure to improve as the plant grows stronger. A *Kegonias*, which received an Award of Merit from the Royal Horticultural Society, was passed over; and Victoria Regina, a very handsomely spotted variety, and a fine plant, received an Award of Merit, as did also *O. Warburtonianum*. Mr. Warburton showed what is probably the finest Cattleya Warszewicz delicata that has ever been exhibited. The flowers of exquisite size form, white segments, and a large, well-expanded lip, furnished with a circular spot of orange, resting on a flesh-colored lower extremity. This should have received an award. There was also a bright-colored *Dendrobium noble nobilis*, and several other good things.

THOMAS STRAYER, Esq., St. Paul Hill (Mr. R. Johnson, gr.), also had a First-class Certificate for *Cypripedium × rubens* (*bellatulum × collossum*). The colours here are very vivid, and so is the spotting. The same gentleman also obtained an Award of Merit for *C. × bellatulum × C. bellatulum × C. Rothschildianum*. The petaliferous segments here are twisted unlike the mould-boarded *C. × piperitum*, and although the coloring is not so striking, the formation is singularly attractive. There were *Dendrobies* in some variety, and a finely grown piece of *Geoglyca cristata* also.

W. THOMPSON, Esq., Walton Grange (Mr. Stevens, gr.), had some particularly fine *Odontoglossums*. The flowers of *Odontoglossum* excellens were as large and as full as the finest *O. Pescatorei*, the yellowish shading on the lints being very captivating, the flower justifying the award of a First-class Certificate. All the rarest and best of the new *Odontoglossa*

were represented in this exhibit, including *O. Wilckeanum*, an *O. Pescatorei* of old formation, its panicle-bearing by all but disappearing; *O. truncatum*, and *O. luteo-purpureum*, the latter with two spikes, each with twenty flowers, being singled-out as meriting a Cultural Commendation.

S. HECULIERE, Esq., Hale, had a fine group of well cultivated plants—nothing very rare amongst them, but casting a dash of colour all over. An example of *Dendrobium Wardianum*, which received a Cultural Commendation, was loaded with hundreds of flowers, and had one individual growth of about 7 feet high. His specimen of *D. nobile* was also crowded with flowers, and a most effective specimen plant. There was also a capital specimen of the beautiful white-lipped *Miltonia* *concolor*, and another of good character. **A. G. WEST, Esq., Breakland**, showed a fine piece of *Dendrobium melanodesmum*, a rather showy *D. Owenianum*, a very rich-coloured *D. nobile nobiliss*; the new *Dendrobium × Breuchluranum*, said to be a cross between *D. nobile* and *D. Wardianum*, but showing traces of *D. splendissimum grandifolium*.

Archdeacon RAWSTON, Balderstone Grange, exhibited a well-flowered plant of *Dendrobium Hillebrandii*, which received a Cultural Commendation. **E. F. MOORE, Esq., Bourton-on-the-Water**, received a Cultural Commendation for *D. macrophyllum superbum* loaded with flowers.

The nurserymen's exhibits were upon the whole very good. **M. BRUXE, of Chesham**, had a fine lot of the former, and being rewarded for his pains with the Society's Gold Medal. We have seen Mr. Cypher shrouded in *Dendrobium* than on this occasion, still he showed a grand lot of well cultivated plants; *Dendrobium Cypheri* was very well shown. It is a fine light form of *D. nobile*, and is well situated; *D. nobile* and *D. g. Dendrobis*, but there are so many now of *D. nobile* and *D. Ainsworthianum* section that one tires of looking at them. *D. × hillebrandii* is a good break of the *D. luteolum* type, and its singular spoon-shaped lip makes it different from most others. There are also several *Epiphyllums* of the rhizophorous-order exhibited by this firm, the bright orange-scarlet and prolific-flowered *O. Brimicum* being one of the best. The *Odontoglossum* were well represented, and *Miltonia* of the *Rosei* order; also *O. Halli kenoglossum* and *O. luteolum*, *Cypripedium* *melanodesmum* in quantity. In regard to *Cypripediums* and *C. Elliottianum*. *C. ciliolatum*, one of the best both for show and breeding, was finely shown in this group. An Award of Merit was voted this group.

Mr. JOHN ROBERTS, Bowdon, decorated the orchestra with the best lot of *Orchids* yet shown. It was brilliant with lots of *Dendrobies*, one of which, named *Robson's nobile giganteum*, received an Award of Merit. There were several good *Lycaste Skinneri* here, well grown and flowered; and the group of *Cymbidium carneum* was particularly noticeable. Other *Cymbidiums* of the *Lowii* section were prominent, one or two good plants of the *Glaucum* variety; *D. splendissimum* nicely in flower, and quantities of the white *Coleogyne* formed a fringe to the whole.

Messrs. CHARLESWORTH & Co., Bradford, had some choice plants; and a First-class Certificate was awarded them for *Sophr. Lælia*, *Mordani*, which represents a *Lælia flava* and *Sophrontes* combined, bringing out a singular mixture of orange and red, thereon amalgamation of the two species which is probably more scientifically than commercially useful. The Award of Merit was given to *Cattleya Trianae*, with the perfectly-formed segment of *lancea* flesh, and an unusually large inflated lip of a rich ruby colour, with an orange blotch, marking the column, was well merited. Flowering plants of *Cymbidium Lowianum* in fine variety, and the pretty *Cypripediums Druryi* and *Euryclæa*, as well as the handsome *C. siliquigerum*; *Odontoglossum septimum superbum* (Award of Merit) of large size and flowers of good substance; and some excellent *O. crispum* were observed.

Messrs. HEATH & Co., Chesham, had a fine lot of *Dendrobium*, *Cypripediums*, and *Odontoglossum*, but they were far too crowded to be effective. We noticed some *O. crispum* of fine quality, and an extra fine *O. luteo-purpureum*, *Cypripedium caudatum*, and *C. niveum*, as well as *C. Fatio-Lanceanum*, and a particularly rich-flowered *C. ciliolatum*.

Messrs. B. S. WILLIAMS & SON had a miscellaneous lot of spring-flowering plants. The *Orchids* were choice, and the singular *Cirriophorum picturatum* commanded attention—the lip of this flower is like a canoe, and the flowers are set in a semi-circle. *Madevella Schrebleri* is one of the brightest novelties we have seen. An Award of Merit was given to *O. crispum* *superbum*, for colour only we presume, also an Award of Merit for a margin coloured *O. crispum*—an acquisition.

Messrs. LEWIS & Co., Southgate, had several good hybrid *Cypripediums*. *Odontoglossum nutans superbum* received an Award of Merit; the flower was of fine form, the spreading and blotching being bright, and the plant was well cultivated. An extra fine *O. Pescatorei*, with fine flushing and some spots, was exhibited; also the rather pretty *Cattleya dolosa hibernica*.

Messrs. R. F. KEN & SOSS had a grand collection of *Andropogon* conspurcator among them, a self-scarlet *King*, and *Sagittæ*, a very good match; *Ema* and *Niobe* are great improvements in the *margarita conspicua* colour type; and *Euryclæa*, and, in fact, many others, are clear in colour, good in substance, and in form.

Messrs. DICKSON, BROWN & TAIT had a fine collection of *Andropogon*.

Messrs. DICKSON, ELL, Chester, had excellent *Daltonia* and showy cut border flowers.

Thos. BROSSE, Esq., Llanthony, sent charming boxes of cut orchids and cut border flowers.

Mr. P. WEARNE sent a very fine *Odontoglossum trianthum* from the garden, with a spike 18 inches long, and full of rich flowers.

LAW NOTES.

ASSESSMENT OF GLASS-HOUSES AND GARDEN LAND.

The assessment of glass-houses and garden land in the Brentford Union is still giving a great deal of dissatisfaction to market gardeners and fruit and flower growers, and recently quite a long list of appeals were disposed of by the Assessment Committee of the Union, with very slight reductions made in a few cases. The valuation list was prepared last year by Mr. C. F. Jones, professional valuer to the guardians, and in September last several appeals were made without avail. This year the appellants were fortified by the expert evidence of Messrs. Protheroe & Morris, a member of whose firm stoutly contested each assessment. Nearly all, however, were governed by one point—how the land should be assessed—as building land, or as it stood from year to year.

In the chief case taken, that of a florist at Cbiswick, the land was situated close to the main road, and in extent it was 2½ acres; the appellant paid £3500 for it, and upon it he erected a handsome show conservatory, costing between £600 and £700, and there were other houses of smaller character, the total spent on the buildings being £1675, the outlay for site and buildings being £5175. Upon this the Assessment Committee placed an assessment of £223 gross, £175 ratable. By the appellant it was contended that the price given for the land was excessive, but inasmuch as appellant's father and grandfather had held it, there was some sentiment in the matter, and moreover it was near appellant's shop. The rent it was really worth was £10 an acre, or £25 in all. The wh-house was an extravagant structure, and worth only a value of £425, and the other houses could be erected at 4d. per cubic foot, which equalled £550. There were some more houses valued at £709 12s. 4d.

Upon these figures, appellant contended that he was entitled to 75 per cent. upon the buildings; upon the show house the value should be 5 per cent. only with a fifth deduction, and the other buildings should be dealt with in the same way. The gross should be £117, and ratable £92. It was further contended that it was contrary to the Act of Parliament to rate the land as building land. If it were so taken, all the buildings should be taken off it and without them, no person of the appellant's trade could carry on his business. He obtained the land for the purposes of his trade, not as a building site.

The real way to deal with the question of the land would be to take it, what it would be let for from year to year after making the necessary deductions for outgoings and repairs. Replying to these various arguments, the committee urged, that on appellant's own figures, he brought the total up to £5175, and upon that, he would surely not be content with less than 4 per cent. profit. They looked at it from a common-sense point of view, that if he did not make that at the least, the site was so valuable for building that he could sell it in building plots. Obviously, appellant derived a great advantage from having his houses at that price, or he would not go outside the London area, where he could get land at 30s. an acre good enough to put glass-houses on. He would not have thrown £3500 capital away over the land—even from sentiment—if he did not see that he was going to get some good value from it as a return. They declined to entertain the view that they were bound to put a value upon the land irrespectively of the price paid for it. It was near appellant's shop, near his customers, the rail and the main road. If a man had what was good building land, which in Chesham had the price of 10s. an acre, and he would use it in any other way, the committee was in no way bound to rate it as if it were out in the middle of the country. They confirmed the assessment, and left the appellant to go to Quarter Sessions if he were still dissatisfied.

In the course of another case which came from Twickenham, the committee urged as a ground in support of raising an assessment on houses, that next year half the rates would be allowed under the Agricultural Rating Act. Mr. Morris, in reply, urged that this had nothing whatever to do with the matter of local assessment. That was a matter for the Imperial Exchequer solely. The remainder of the committee was that it enhanced the value of land in the rural, because a large part of the deductions in the

nature of outgoings was taken off. If part of a man's rates were paid him, he must reap a benefit, and this should be taken into account in considering the lettable value of the land. Mr. Morris demurred to this view. The Act was passed to benefit the tenants; here was the assessment committee making a tenant suffer for it, and obviously using it as a lever to get more out of him. It was deliberately attempting to take away all the benefit which the Act conferred. The Act might only be in force for five years, and at the end of that time it was reasonable to suppose that assessments would be granted with no reduction in consequence. The committee in this case granted a small abatement.

CHARGES FOR GARDEN WATER.

Judge Bagshawe, of the Brentford County Court, sat in his private room at the Middle Temple on Saturday last, for the purpose of concluding the case of the "Grand Junction Waterworks Company v. Cowley." In this case, Mr. Victor Cowley of Ealing, Secretary to the Ealing Water Consumers' Protection Committee, was sued by the company for £1 ls. for water used by the defendant for other than domestic purposes—namely, for garden purposes during the season of 1896; or, alternatively, for £1 ls. damages for the use by defendant of water of the plaintiff's for such purposes during such period. The case was defended for the purpose of obtaining a decision from his Honour on the legality of the company's insistence upon the minimum payment of a guinea a season for water supplied for garden purposes irrespective of the size of the garden. It was admitted that water was used in defendant's garden during the season of 1896, and that the company had a right to make a special charge for it; the defendant had, therefore, paid 5s. into Court, and denied further liability. Judge Bagshawe, in giving judgment, said that he found the offer to supply water to gardeners by means of a hose for the sum of 1 guinea was reasonable, and the use of the water was an implied acceptance of the terms imposed by the company. In fixing the charge, the company were bound to take into account not merely the minimum amount of water used, or even the amount used by the reasonably-minded consumer, but also that taken by the numerous body of consumers who construed their rights with the utmost liberality towards themselves. Considering all this, he held the charge of 1 guinea to be fair. He gave judgment for the company for the amount claimed, with costs upon the highest scale. He also certified, for the purposes of an appeal, that the question litigated was of importance, and of general and public interest.

Obituary.

MR. J. CRUICKSHANK, FROMGORE HOUSE GARDENS.—To the numerous gardeners who, as young men, have, during the last fifty years, been through the Royal Gardens, Windsor, the news of the sudden death of James Cruickshank will be received with much regret. Although seventy-two years of age, he enjoyed good health, and died practically in harness, as he was attending to his duties on the day of his death, March 4. He came to the Royal Gardens from Castle Fraser, Aberdeenshire, in July, 1847; consequently, had he lived till July next, deceased would have completed fifty years in the Royal service as a journeyman in the various departments for seven years, and was appointed foreman in the Castle Gardens and Slopes, where he remained another seven years; and when the Crown took over Fromgore House on the death of H.R.H. the Duchess of Kent, in 1861, he was appointed foreman of Fromgore House Gardens.

He was a gardener of the old school, with a good knowledge of hardy plants and shrubs, also wild flowers, and could tell many a good tale of the rambles he took in Scotland, in search of new and rare species, during his boyhood. Being of a happy and jovial disposition he was very popular, and never happier than when quoting "Lobby Burns," whose poems he seemed to have learned by heart.

The funeral took place at Windsor Cemetery on the 9th inst., and was largely attended, the remains being followed to the grave by Mr. O. Thomas, the Queen's head-gardener; Mr. W. Tait, bailiff; all the foremen at the Royal gardens, deceased's men, relatives, &c.

Among the many handsome wreaths sent to his funeral, as tokens of sympathy and respect by numerous relatives and friends, was a beautiful one of immortelles, having on a card attached, "From Queen Victoria."

ENQUIRY.

"He that questioneth much shall learn much."—Bacon.

HIPPEASTRUMS IN JADDO.—Will some of our correspondents inform "Anateer" if Jaddo is a suitable material for Hippeastrums. He planted some in it, but the old roots look shrivelled and inclined to rot. What kind of treatment would be suitable?

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named: and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

Table with columns for TEMPERATURE, ACCUMULATED, RAINFALL, and BRIGHT SUN. It includes sub-columns for Day-deg., Day-deg., Day-deg., Day-deg., 10ths Inch, and In. and rows for various weather conditions like Above (+) or below (-) the Mean for the week ending March 13, 1907.

The districts indicated by number in the first column are the following:—

- 0, Scotland N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London; 6, Principal Grazing, &c. Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.—Channel Islands.

MARKETS.

COVENT GARDEN, MARCH 18.

PLANTS IN POTS.—AVERAGE WHOLESALE PRICES.

Table listing prices for various plants in pots, including Adiantum, Aspidistra, Begonia, Azalea, Cineraria, Cyclamen, Fuchsia, Dracaena, Evergreen Shrubs, Erica, and Ferns.

ROOTS FOR THE GARDEN IN VARIETY COMING VERY GOOD.

FRUIT.—AVERAGE WHOLESALE PRICES.

Table listing prices for various fruits, including Apples, Grapes, Currants, Figs, and Peaches.

OUT FLOWERS.—AVERAGE WHOLESALE PRICES.

Table listing prices for various out-flowers, including Anemones, Arums, Azalea, Bouvardia, Carnations, Blooms, Eucharis, Hyacinth, Lilac, Liliun Harris, Lily of the Valley, Maidenhair Fern, Marguerite, Mimosa, Nerissus, and Orchid-bloom.

VEGETABLES.—AVERAGE WHOLESALE PRICES.

Table listing prices for various vegetables, including Artichokes, Chinese, Asparagus, Beans, Cauliflowers, Cabbidowers, Carrots, Cauliflowers, Cauliflowers, Corn, Cucumbers, Fennel, Horseradish, Kidney Beans, Leeks, Lettuce, Onions, Peas, Potatoes, Pumpkins, Radishes, Spinach, and Tomatoes.

Fresh arrivals have sold rather more freely the last few days, but there are no signs of any improvement in prices. Lincoln Saxons, 29s. to 69s.; do, Maincrop, 55s. to 71s. John Bull, Wellington Street, Covent Garden.

BOOKS.—C. O. L. Silver Ferns and Lyopods, by B. S. Williams & Son, Victoria and Paradise Nurseries, Upper Holloway, N.—The Fern. Bullion's Histoire des Plantes, in several volumes.

COAL ASHES: A. P. We agree with you that coal-ashes are of little or no value as manure, and not worth the cost of cartage. Wood-ashes with liquid manure are much more valuable. We thank you for your communication on the Potato disease, but we can no longer be the last of the party. It is caused by the growth of a fungous mould which produces the effects you so graphically describe. The spores, or seeds, are in the air, and fall on the plant. When the weather is favourable to the fungus, it grows and destroys the Potato-plant, but if the weather is unfavourable to the growth of the fungus, then, of course, the Potato-plant does not suffer.

CROCUS FOR PLANTING IN THE TURF: Crocus. If you require Crocus to flower in the autumn, you should plant C. nudiflorus, C. speciosus, C. odoratus, C. sativus, C. serotinus, C. Pallasiana, &c. Spring-flowering Crocus (which are more numerous, might include C. vernus [var. versicolor] the common variegated spring Crocus, of which the bulb-growers have many varieties; C. Susimans, small and deep yellow—there is a purple variety of this species; C. aureus, C. nivialis, C. Adonis, in many varieties. The best practice in regard to Crocuses planted in the grass, is to group them in compact patches—not scattering them all over the surface—which answers well enough for Snowdrops, whose foliage matures earlier, and therefore need not hinder a lawn being mown in April. The turf

of these patches should remain unmown till May or later, according to the character of the season. GRATING-WAX: B. G. S. Bees-wax, and as much bested or tallow as will make it workable. Melt the bees-wax in a glue-pot or similar arrangement over a fire, and add the fat by degrees, occasionally testing the consistency of the mass. When cold, it should set somewhat hard, with a shining surface, but should not crack in cooling. This kind of grating-wax should be used warm. There are other recipes, but this one is simple and good.

INSECTS: M. B. Dorset. We have carefully examined the Cucumber soil and the specimen in the match-box, and can find no worms whatever. From your letter we suspect that it is wireworms that are causing the mischief.—W. X. H. We were unable to discover the insect. Nothing was in the bottle but a fragment of a growth of Cattleya.

LOUIS: R. H. We do not advise you to grow them in pots, but in the tanks.

MOLES and "HOGNICE": W. C. If trapping does not lessen their numbers, we are unable to suggest a remedy. By "hognice" you probably mean the short tailed field-mouse or vole, which some eats will kill and eat, all but the incisor teeth and feet. We should suppose that the balance of Nature has been disturbed by the gamekeepers of the locality, killing off the carnivorous birds and small quadrupeds. Everything is sacrificed in some places to the rearing of pheasants, master and man being equally unhelpful.

NAMES OF PLANTS: Correspondents not answered in this issue are invited to go on as usual to send the following number:—J. L. 1, Chirlopentium picturatum; 2, Dendrobium aggregatum.—A. G. The small form of Brassia verrucosa.—J. T. Every spring we get a number of fine forms of Dendrobium Wardianum from fresh-imported plants, but our experience is that, although the plants which bore them may again produce good flowers, they never come so good again as the flowers (often only one or two on a plant) which first appeared under cultivation. Your No. 3 is a grand flower. No. 2 would be a good form of D. W. candidum, but for the present, flash on the petals. It is, however, a very pretty variety, and will always be distinct. No. 2 is above the average.—R. G. A very fine form of Dendrobium Wardianum. See reply to "R. T."—E. P. Phaius maculatus.—C. W. A. The yellow-tinted flower is a very good form of Orlotoglossum Andersonianum. The other a blotched variety of Orlotoglossum crispum, with a slight suggestion of O. Wilckeanum albens about it. It is difficult to say how many of these variable Orchids are of hybrid origin.—C. B. H. Your plant is Asparagus plumosus var. carduus, and A. p. and is the same, the best of the best. It is the result of cultivating the plant in small pots, or confined spaces. Afford it good rich soil, and plenty of space for its roots, and the climbing robust habit soon shows itself.—Amicus. The Cedar of Lebanon.

NOTICE TO QUIT EMPLOYMENT: G. A. P. The customary period of notice for a gardener to quit his situation, in the absence of any written agreement or willful wrong-doing, is one month.

PERFUME SHRUBS: Primrose. You must please be more explicit, perfumers use so many shrubs for their purposes. Perhaps you mean Lavender.

VIOLETS AND PRIMULA: G. Beatrice. The Violets show good cultivation; and the winter having been generally of a mild character has favoured the flowering of your plants. The Primula is one of the so-called blue-flowered varieties, of which there are many, variegated but little in their colouring.

WHAT DISTANCE TREES MAY BE PLANTED FROM DIVIDING LINES OF PROPERTY: R. Maitre, New Orleans. We have no law which determines the distance at which trees, &c., may be planted, and the matter resolves itself into an arrangement between the parties interested; or an aggrieved party can bring an action in the courts against the owner of the adjoining trees, &c., for deprivation of light, injury to his land, &c.

COMMUNICATIONS RECEIVED.—J. D. we followed the official list. A. E. B. J. Corley.—E. A. B. M. B. Middleburgh.—The William Berlin, & Co. J. V. Versailles. A. O. C. H. P.—H. J. H. F. E. R. E. W. C. W. THE

Gardeners' Chronicle.

SATURDAY, MARCH 27, 1897.

JUAN FERNANDEZ.

THE appearance of a new "flora" of these beautiful and highly interesting islands is perhaps sufficient justification for giving some particulars of their history and vegetation in this place, especially as the original is in Spanish, and therefore not likely to come under the notice of many of the readers of the *Gardeners' Chronicle*. To save the reader the trouble of looking them up, I will give some particulars from my own account of the islands in the *Botany of the "Challenger" Expedition*, merely premising that the figures relating to distances, &c. are approximations. Originally, the name Juan Fernandez was applied to a group of three volcanic islands, of which the two principal were called Masatierra (meaning nearer the mainland) and Masafuera, indicating their respective positions with regard to the mainland. In this country, the name Juan Fernandez is ordinarily applied to Masatierra only. This island, which is much the larger of the two, lies in about 33° 45' S. latitude and 80° W. longitude, or about 400 statute miles from the coast of Chili. The area is about 20 square miles, and the greatest altitude 3000 feet. A mile to the south is a small island called Santa Clara, or Goat Island. Masafuera is some ninety miles westward of Juan Fernandez. It is a rocky mass, having precipitous coasts, extremely difficult to land on.

Juan Fernandez? was a favourite resort of the buccaners in their expeditions against the Spanish possessions in South America, and the scene of many strange, exciting, and even romantic events; not the least of which was Alexander Selkirk's solitary existence in the island during a period of four years and four months. It is almost superfluous to mention that it is generally believed that the events of Selkirk's life in Juan Fernandez formed the foundation of Defoe's famous and familiar novel, *Robinson Crusoe*; though, from motives of his own, the author transferred the scene to an island off the mouth of the Orinoco river in the West Indian seas. But those who read the narratives of the early voyagers in the Pacific know that they contain materials for many a story. As a matter of fact, Defoe's inspiration may have been derived from the adventures of an earlier sojourner in the island than Selkirk, as set forth in Captain William Dampier's account of his first voyage round the world, in a privateer ship, as he himself designated it. They arrived at "John Fernando" in March, 1681, and they went ashore, as

Dampier relates, to seek "a Mosquito Indian," whom they had left on the island when they were chased hence by three Spanish ships in the year 1681. I venture to extract the paragraph in Dampier's narrative relating to this man's captivity in the island, although it is neither horticultural nor botanical:—

"This Indian lived here alone above three years, and although he was several times sought after by the Spaniards, who knew he was left on the island, yet they could never find him. He was in the woods hunting for goats when Captain Watlin drew off his men, and the ship was under sail before he came back to shore. He had with him his gun and a knife, with a small horn of powder, and a few shot, which being spent, he contrived a way, by notching his knife, to saw the barrel of his gun into small pieces, wherewith he made harpoons, lances, hooks, and a long knife; heating the pieces first in the fire, which he struck with his gun-flint and a piece of the barrel of his gun, which he hardened—having learnt to do that among the English. The hot pieces of iron he would hammer out and bend as he pleased with stones, and saw them with a jagged knife, or grind them to an edge by long labour, and harden them to a good temper as there was occasion. All this may seem strange to those that are not acquainted with the sagacity of the Indians; but it is no more than these Mosquito men are accustomed to in their own country, where they make their own fishing and striking instruments, without either forge or anvil, though they spend a great deal of time about them. . . . With such instruments as he made in that manner he got such provision as the island afforded, either goats or fish. He told us that at first he was forced to eat seal, which is very ordinary meat, before he had made hooks; but afterwards he never killed any seals but to make lines, cutting their skins into thongs. He had a little house or hut half a mile from the sea, which was lined with goats' skin: his couch or bartec of sticks lying along about 2 feet distant from the ground, was spread with the same, and was all his bedding. He had no cloaths left, having worn out those he brought from Watlin's ship, but only a skin about his waste. He saw our ship the day before we came to an anchor, and did believe we were English, and therefore kill'd three goats in the morning, before we came to an anchor, and dress them with Cabbage, to treat us when we came ashore. He came then to the sea-side to congratulate our safe arrival."

I will conclude these allusions to the probable original, or originals, for he may have drawn something from both, of Defoe's hero by adding that Alexander Selkirk joined a privateering expedition organised by Dampier, which sailed from Kinsale in 1703; and he was left on the island at his own request in October, 1704. The first edition of *Robinson Crusoe* was published in 1719. Dampier was unfortunate in his expedition, but he was accompanied Captain Woodes Rogers on a later one, and was with him when Selkirk was rescued in 1709.

Dr. Johow's *Flores* contains very few indigenous plants not included in my enumeration in the *Botany of the "Challenger" Expedition*. His is altogether a much more comprehensive work than mine; yet I am gratified to say that he gives me full credit for what I was able to accomplish under less favourable conditions. He has spent several months in the islands, and from actual observation and study of the plants in their homes has been able to correct some of the errors of previous writers; and, although he describes half-a-dozen new species, his total is rather less than mine, in consequence of the rejection of a number of spurious species.

All travellers agree in describing the vegetation of Juan Fernandez as very beautiful, which the admirably executed views in Dr. Johow's

attractive book fully confirm. As in most remote islands, the number of species, as compared with the nearest continental areas of the same extent, is small, whilst the number of genera and orders represented is relatively large. Dr. Johow's numbers are:—143 species belonging to eighty-seven genera and forty-three natural orders. These numbers include only the flowering plants and Ferns, almost half of which are peculiar to the island, and forty-two out of the total are Ferns. Singular to say, not a single Lycopodium, nor a Selaginella, has been found; yet filmy Ferns abound, there being upwards of a dozen different species. Noteworthy among the Juan Fernandez Ferns are *Dicksonia Berteroana* and *Thyrsopteris elegans*, the latter an endemic genus of one species.

Apart from Ferns, few of the plants peculiar to the island are in cultivation; and, indeed, few of them are particularly suitable for cultivation.

Here, as in many other islands—St. Helena, the Chatham group, and the Galapagos, for example—small arborescent Compositae, many of them resiniferous, form a noteworthy feature in the indigenous vegetation. The genus most numerous in species is *Robinsonia*, so named by De Candolle in commemoration of DeFoe's hero; but *Dendroseris*, belonging to the same group as the Sow-Thistle, *Sonchus*, some species of which attain the form and dimensions of miniature trees in Madeira and the Canaries, is still more remarkable, on account of the size and showy character of the flower-heads. Dr. Johow describes a new species, *D. gigantea*, from 15 to 20 feet high, "with a trunk as thick as a man's thigh;" and about twenty years ago Messrs. Veitch imported and flowered *D. macrophylla*, a species of somewhat smaller dimensions, having deep yellow flower-heads nearly 3 inches across. There is a coloured figure of this in the *Botanical Magazine*, pl. 6553. It was sent home by Mr. Downton, collector for Messrs. Veitch, who also discovered, in the same island, the beautiful *Wahlenbergia tuberosa*, *Botanical Magazine*, pl. 6155.

Another composite was named *Vendredia* (from *vendredi*, French for Friday) by the late Dr. Baillon, after Crusoe's man Friday, but this name has to give way to the earlier *Rhinodendron*. I, myself, when drawing up my account of the flora of Juan Fernandez, having to deal with a shrubby plant of the Boraginaceae, which had been erroneously referred to *Cynoglossum*, named it *Selkirkia*, on the ground that Selkirk deserved this kind of distinction quite as much as Defoe's imaginary hero.

In addition to some charming landscape views, Dr. Johow figures a number of the more remarkable plants; among them *Dendroseris mirantha*, *Plantago fernandeziana*, *Myrcogonia fernandeziana*, *Gunnera peltata*, *Santalum fernandezianum*, *Juncus australis*, and *Dicksonia Berteroana*. The *Plantago* is remarkable in having a stem from 3 to 6 feet high, in which character it is only equalled by the Sandwich Island *P. princeps*. *Myrcogonia fernandeziana* is the commonest and tallest tree in the island, growing from 60 to 80 feet high; and it furnishes a valuable and durable timber. It is a member of the *Myrtaceae*. *Gunnera peltata* forms a trunk sometimes as much as 20 feet long, the lower part of which is horizontal, and the upper oblique or erect. Its large-peltate leaves are sometimes more than 6 feet across. I believe it is the only arborescent species. From a geographical standpoint,

* *Estadillo sobre la Flora de las Islas de Juan Fernandez*, by Federico Johow. A espensas del Gobierno de Chile. Santiago de Chile: Corvantes, 1896, 4to, pp. 209, with 18 plates, 2 maps, and some figures in the text.

† Which not otherwise explained, or evident from the context, Juan Fernandez is here used in the restricted sense, and is equal to Masatierra.

the Sandalwood—*Santalum fernandoianum*—is, perhaps, the most interesting element in the flora. Until recently, its existence was little more than traditional, though dead wood found in the main island had been declared by experts to belong to the genus *Santalum*. Bertero in 1830, and Gay in 1849, mention a Sandalwood as having been abundant, and the latter refers it to *Santalum album*, and states that it all perished, or was destroyed, in one year, though by what agency he does not inform us. Its recent history is this:—In 1868 branches of a pleasant-smelling wood, bearing a few leaves, were found amongst some fuel purchased for one of the ships of the Chilean navy. This was microscopically examined, and identified as Sandalwood. In 1888 Mr. F. Philippi succeeded in obtaining a small bundle of twigs bearing leaves, and one of them a few flower-buds; but it was not till 1892 that he ventured to publish it under the name given above. Still, no living example of the tree had been seen by a botanist. As Dr. Johow says, the reader will understand his joy, after five weeks' fruitless searching, and the offer of a substantial reward, on being shown a tree of respectable dimensions by a colonist, Pedro Arredondo. This tree was about 30 feet high, with a trunk 4 feet 6 inches in girth, and it was situated in the middle of a wood in Masatierra. Fortunately, too, it was in flower, so that Dr. Johow was able to complete the description of the species, which is closely allied to *S. Freycinetianum*, a native of the Sandwich, Marquesas, and Society Islands. The interest attaching to the discovery of a true Sandalwood in Juan Fernandez may be realised from the facts that no species inhabits the mainland of America, and the nearest habitat of any other species of the genus is in the Marquesas Islands, some 3500 miles distant from Juan Fernandez. From Dr. Johow's researches, there is now no doubt that Sandalwood was formerly abundant, both in Masatierra and Masafuera. The lucrative nature of the Sandalwood trade led to the almost total extinction of the trees, not only in Juan Fernandez, but also in the Sandwich and other islands in the Pacific. Seemann (*Flora Vitiensis*, pp. 209—215), gives a brief history of the Sandalwood trade in the Pacific, from which it is evident that it was carried on in the most reckless manner, and at an appalling loss of human life, both among the ferocious natives and the unprincipled traders of various nationalities.

The Chonta, or Palm of Juan Fernandez, *Juania australis*, is endemic in Masatierra, where, contrary to Mosley's impression, it is still abundant, being spread all over the wooded part. It is described as very slender and graceful; the trunk, though rarely exceeding 8 inches in diameter, rises high above all the other trees of the forests, where its head of waving feathery leaves is very effective, and when adorned with festoons of its scarlet fruit it is very striking and attractive. It is now in cultivation at Kew and elsewhere, and likely to become as great a favourite among half-hardy Palms as *Howea Belmoreana*, from Lord Howe Island.

The tree Ferns, three in number, *Alsophila pinnata*, *Dicksonia Berteroana*, and *Thyrsopteris elegans*, constitute a beautiful and graceful feature almost everywhere in the woods, or forests as they are generally designated. Dr. Johow gives a view in which tree Ferns form a lovely foreground, and he also gives the portrait of a plant of *Dicksonia Berteroana*, having

several stout lateral branches. This Fern, he says, attains truly gigantic dimensions in Masafuera. All three of these Ferns are in cultivation in this country.

In conclusion, I can only add, that Dr. Johow's book does great credit to him and the Chilean Government, at whose expense it was published, and will perpetuate some of the beauties of the historically and botanically interesting Juan Fernandez. *W. Botting Henesley*.

ORCHID NOTES AND GLEANINGS.

DENDROBIUM NOBILE NOBILIUS.

In the language of the astute advertiser, "Imitation is the best evidence of Merit," but where applied to very fine and totally distinct varieties of showy

FIG. 59.—AN OLD AND DEFECTIVE METHOD OF RIND-GRAFTING. (SEE P. 199)

but variable species of Orchids, it gives a lot of trouble to those who wish to be accurate in their names. Few plants have had their names appropriated more than *Dendrobium nobile nobilius*, the true stock of which can only proceed from the weakling picked up by Mr. James at Stevens' Rooms some twenty years ago, and which, after being nearly killed by being exhibited by Messrs. Rollison at the great quinquennial exhibition at Ghent in 1878, found its way back to its original owner, who from the pseudobulbs (for the leading growths were dead) succeeded in raising half-a-dozen plants, from which all the plants that are true to name have come. *D. nobile nobilius* is not an ordinary case of variation, for to one who knows its stout, tall growth, and its richly coloured flowers, there is nothing like it. And yet scarcely an importation of *D. nobile arives* which does not produce varieties which in the eyes of their affectionate owners are either the true thing, or better. On the continent it is even more badly represented than in England, and it is re-assuring to

get flowers of the right thing, taken from a plant of the original stock, from Messrs. Linden, of Brussels. They are a little over 4 inches across, and the sepals and petals are of that deep rich amethyst purple so peculiar to the variety. There are plenty of good and finely-coloured *D. nobile*, but there is but one *D. nobile nobilius*, and the only chance of confusing it with another is to get a badly-grown specimen of it to compare a well-grown example of another dark form with. *J. O'B.*

EULOPHIELLA ELISABETHÆ.

Few Orchids of recent introduction have been so well received as *Eulophiella Elisabethæ* when offered in quantity by Messrs. Protheroe & Morris for Messrs. F. Sander & Co., in June and July, 1893. The plants then sold were good and sound, and there seemed to be nothing to prevent the plant becoming a useful subject, and a general favourite. But when cultivators began to compare notes of its behaviour in their hands it soon acquired the reputation of being "a bad doer;" a character it seems to have deserved, for probably but a small percentage of the importation now exists. But as with most other plants of bad repute an occasional specimen is met with growing in the most vigorous manner, giving no trouble to the grower, flowering regularly and profusely, and thus demonstrating that it is from no peculiarity in the plant itself that failure arises, but from a want of knowledge of how to treat it, or a lack of the necessary convenience. A case in point is the specimen of *Eulophiella Elisabethæ*, purchased by Gen. C. Raphael, Esq., Castle Hill, Englefield Green, Surrey (gr., Mr. H. Adams), at the first sale in 1893, and which has flowered grandly every year. At present the plant bears three stout spikes, averaging thirty-five wax-like white flowers, tinged with purplish-rose on the reverse side. The plant is grown in a warm, rather moist house, and is kept well supplied with water at the roots, especially while in active growth.

CATTLEYA WARNERI

grows to a height of about 16 inches, the leaves being about 3 inches across, of a thick leathery texture, dark green in colour. The flowers are large and showy; they are sometimes produced with as many as five on a spike, but this is an unusual number. It should be grown in a pot or a basket suspended from the roof of the house, in a compost of peat and sphagnum-moss. It requires a good amount of heat during the growing season, which is in the winter and spring months; the flowers are produced from the uncompleted bulb. This is matured soon after the flowering time is over. The plant requires a good season of rest, and during this period water should be withheld, only just sufficient being given to prevent the shrivelling of the bulbs. *Orchid Album*, vol. xi., part 131, p. 521.

DENDROBIUM TRANSPARENS ALBUM

Requires the same treatment as that given by us for *D. transparens* in vol. ix. of this work, plate 396. Like the type, it is well adapted for growing in small teak-wood baskets, or in shallow pans, so that they may be suspended near the roof-glass, fully exposed to the sun and light; some shading, however, will be necessary when the sun is very powerful. An abundant supply of moisture to the roots as well as in the atmosphere, and a judicious admission of air, are conditions essential to the welfare of the plant. During the growing season especially, the supply of water must be liberal, but during the resting period it may be reduced to a minimum, just sufficient water being required to prevent the pseudo-bulbs becoming shrivelled. As the species flowers after the resting period, the plant requires a moderate amount of water at its roots as soon as the flower-buds begin to show to enable the plant to develop the flowers, which will last much longer in beauty when properly nourished. *Orchid Album*, vol. xi., part 131, p. 522.

CYMBIDIUM TIGRINUM

was discovered by the Rev. C. S. Parish in the mountains of Tenasserim, at an elevation of 6000 feet, as far back as 1893; it is, however, far from common in collections, as importations are neither large nor

numerous. The cool end of the Cattleya-house will be found most suitable for this plant. It should be potted in a compost of good rough fibrous peat and loam, the latter material predominating, with ample drainage. Plenty of pot-room should be given, as the plant produces thick, fleshy roots freely. During the growing period a copious supply of water will be found essential, which afterwards may be gradually diminished. Propagation may be effected by dividing the pseudo-bulbs. The plant which forms the subject of our plate, flowered in the collection of H. S. Leon, Esq., of Bletchley Park, Bucks, where so many choice specimens of Orchids bear testimony to the able management of Mr. Hislop, the gardener. *Orchid Album*, vol. xi., part 131, pl. 523.

CYRIPEDIUM GRATRIANUM.

To succeed well in growing this plant, it should be potted in a mixture of brown peat fibre and living sphagnum-moss; ample drainage should be given, as otherwise the peat is apt to become sour, which

counties, from my instructions, and has proved a success during the last three years, a vigorous growth having always followed. It can be employed upon stocks varying in size from half-an-inch to an inch-and-a-half in diameter, and scions may be made from wood one or two years old in the case of fruit-trees.

Fig. 59 represents an old mode of rind-grafting, the defects of which can be seen at the place of union. Figs. 60, 61, illustrate the preparation of stock and scion for the method that I advocate—in the one case upon a small stock, and in the other upon a larger one. In fig. 62 the graft is shown when completed and waxed, and in fig. 63 is illustrated the effect of one year's growth after the grafting has been done. It will be seen to offer more than ordinary resistance against the wind. For the living specimens I send you I am indebted to Mr. Crawford, gardener, Severn House, Ironbridge, and to his employer, as showing the use made of my instructions in the gardens there two years ago. *Robert Smith, Horticultural Instructor, Shropshire County Council.*

cultivation—the truth being that not one of these bulbs out of every hundred outlives its second season in the open air. The same statement is true of the pretty cream-coloured form of Trumpet-Daffodil known as *pallidus procerus*, which collectors have done their best to obliterate from its headquarters in the Basses Pyrenees. At the time of its first introduction in quantity, a dozen years ago, one of the largest growers of Narcissus for cut bloom invested considerable sums in bulbs of this last plant, but it speedily showed its resentment of cultivation, and disappeared. On some soils it will live for a few years if planted in turf, but I know no other way of keeping it alive. Of the beautiful little pure white pseudo-Narcissus, *N. moschatius* of the High Pyrenees, even this much cannot be said, for except in a very few localities of quite exceptional soil and climate, it is ungrowable. My advice to those who admire the small wild species of Narcissus mentioned, is to grow them in successive generations from seed, sowing it in pots plunged in ashes in a cold-frame.

FIG. 60.—LARGE BRANCHES: GRAFTED ACCORDING TO THE METHOD RECOMMENDED, SHOWING THE GRAFT IN POSITION BEFORE IT IS COVERED WITH WAX.

FIG. 61.—SMALL BRANCHES GRAFTED, AND READY FOR WAXING.

would be fatal to the well-being of the plant. It will be found to do well in the East Indian-house, and during the growing season it requires a liberal supply of water. During the dark and dull days of winter a smaller quantity will suffice, although the plants should never be allowed to become dry; great care and circumspection is therefore required in this respect. The atmosphere also should be kept in a moist state, as otherwise thrips will undoubtedly commit ravages which will permanently disfigure the plants. The subject of our illustration flowered in the collection of S. Gratrix, Esq., of West Point, Whalley Range, Manchester, to whom we have much pleasure in dedicating it. The Orchid collection at West Point is confided to the charge of Mr. McLeod, and bids fair to become one of the finest in the kingdom. *Orchid Album*, vol. xi., part 131, pl. 524.

SMITH'S IMPROVED METHOD OF GRAFTING.

This method of grafting is recommended for fruit or other trees, in the orchard and garden, and especially in exposed situations. The scion has a threefold grip of the stock or branch it is placed upon, and this is covered during the first year by the union. The method has been tested in Shropshire and neighbouring

NOTES ON THE NARCISSUS.

(Continued from p. 184.)

KINDS REQUIRING SPECIAL CULTIVATION.—The geographical extent of the Narcissus is sufficiently wide for some few kinds to come from a low elevation in latitudes which indicate their tenderness in England. The autumn-flowering *N. viridiflorus* and *serotinus*, from North Africa and the extreme South of Europe, can be flowered only in a warm greenhouse, and that not easily. The dainty little *N. monophyllus* or white *Corbularia* demands the un-English conditions of dry sun-heat in summer and shelter in winter, and is altogether too frail for our average spring weather. *N. triandrus* and the European *Corbularias*, or Hoop-petticoats, though some degrees hardier, and grown with fair success in a few exceptionally favoured English gardens, must be reckoned cold-frame plants. They should be dried off and sun-dried in their pots or pans from May to September, and freely supplied with water whilst growing. The same treatment suits *N. cyclamineus*, a most difficult subject in most gardens. Tens of thousands of *N. Corbularia*, *triandrus*, and *cyclamineus* are imported annually, almost, it is to be feared, to their extermination in some of their native places abroad, and are advertised and bought as though amenable to ordinary outdoor

The young plants grow healthily enough up to the time of flowering, after which they die out like the imported bulbs.

The larger forms of pseudo-Narcissus of the High Pyrenees, *N. variflorus* and *abscessus* (*nauticus*), succeed fairly well, but by no means everywhere, under cultivation. To these there is little doubt that our garden bicolor Daffodils, and such vigorous forms as *Emperur*, owe a part, at least, of their parentage, but in their pure form they are fastidious as to soil, like nearly all wild Narcissus, and dislike nitrogenous stimulants. Indeed, the only clear exception to this rule which has come under my notice is the group of yellow trumpet Daffodils, classed as *N. major*. The best known of these, *N. maximus*, is an unmodified wild plant from the Landes, yet thrives in rich kitchen-garden soil. There are, however, difficulties in its cultivation: it is in some years, for no apparent reasons of weather, almost flowerless, and has the perplexing character of keeping its foliage green and unwithered for weeks after all other Narcissus have gone to rest, and thus gives no indication of the proper season for lifting its bulbs. My own experience is that little injury is done by lifting it at the end of June while still green, but that in deep, moist soils it may advantageously be left for some three seasons undisturbed. It is a curious fact that while the garden forms of

N. poeticus, as already noted, will flourish in ground made too rich for other *Narcissi*, yet its wild counterparts, e.g., the Pyrenean and Italian *N. poeticus*, invariably die out in my garden and elsewhere when cultivated, and will live only in grass. The well-known *N. poeticus ornatus*, for instance, will grow almost like a weed in any garden; but a wild plant which closely resembles it, collected by myself in northern Italy, has defeated all my devices to keep it alive elsewhere than in grass. I may here venture an opinion that the suitability of grass-land for some *Narcissi* and other bulbs is not only chemical but mechanical. Certainly, when the turf is broken up (I speak of my own ground), they will not flourish in it as before, though no manure of any kind be added to it. It is not impossible that the turf affords some protection in winter, especially against the alternate freezing and thawing of the surface-soil, which *Narcissi* greatly dislike. It must not be forgotten that many of the wild kinds under discussion are covered, in their homes, by a thick blanket of snow for some months. The drawback to relegating troublesome sorts to the grass is that their flowers are necessarily smaller than when cultivated.

The white garden Trumpets, *N. cernuus*, *albicans*, &c., inherit much of the fastidiousness of the wild *N. moschatus*, from which they are almost certainly descended. Where they fail, as they do over a large part of England, they should be planted in grass; no other kind of treatment by artificial soil or position being permanently beneficial.

The late-flowering double or *Gardenia-flowered* *poeticus*, most valuable for cut bloom in May, requires the very opposite sort of treatment. On poor, and especially on dry ground, a large proportion of its flowers come a "blind" or abortive. It should be planted rather deeply, on ground well dug and enriched, and the beds if possible flooded with water if April be dry. This plant, like *N. maximum*, should be moved only every third year, but should be surfaced every February with old stable-manure or a little dissolved bone-manure.

There is an important section of early-flowering and attractive yellow Trumpet *Daffodils* which has proved very vexatious to the market gardener, namely, that of *N. spiralis*, including such fine varieties as *Arli Right*, *Henry Irving*, *Golden Spur*, and some others. The popular little *Tenby Daffodil*, one of the first to bloom, presents the same difficulty in most districts. Of these kinds the bulbs become rootless and rusty, and the entire plant dwindles away when grown for a few seasons on the same ground. That very handsome *Daffodil*, *Golden Spur*, tends to die out on the Dutch farms in its second season, and is maintained only by a constant interchange of stocks with the English growers. Fresh stock-rotation of crops, and annual lifting, are the only availing expedients.

The larger forms of *N. polyanthus*, or *Tazetta*, are of great beauty, and in mild localities, such as the Scilly Islands, of extreme value as being almost winter-flowering. But the finest of them, such as *Bazelma major*, and *orientalis* (*Muzart*), are of southerly origin, and liable to destruction in winters of unusual severity. In the average English garden they require deep, rich soil on a south border, and may be left unmoved for two or three years. *G. H. Engleheart*.

(To be continued.)

FORESTRY.

THE MINERAL FOOD OF CONIFERS.

Is the *Gardener's Chronicle* of February 13, Mr. J. J. Willis mentions the researches of Prof. Schultz regarding the proportion of phosphoric acid in different classes of soil for Pines. In 1892, Dr. Ramann of Eberswalde published (*Zeitschrift für Forst- und Jagdwesen*, Jan. 1892) the result of some investigations he had made upon the food-supply of the three classes of plantation trees known in sylvicultural language as the "predominant," "dominant," and "suppressed" stems, which constitute the stock of a crowded wood,

Dr. Ramann's researches were confined, however, to the three principal ash-constituents (lime, potash, and phosphoric acid) of the respective stems, and the proportion existing between the weight of needles, and the increase of wood resulting from their assimilative activity, thus furnishing confirmatory evidence on this question.

Dr. Ramann dealt with the Scots Pine growing on the diluvial sand of the North German plains, the selected trees belonging to the "thicket" and "pole" stages, these being twenty and thirty years of age respectively. Three trees out of each stage were taken, one for each of the classes named above. The point Dr. Ramann set himself to unravel was the real cause of the falling-off in growth which occurs in suppressed trees. Two probable causes suggest themselves: 1st, insufficient light; 2nd, insufficient nutriment from the soil. We can only give the more important data from which the doctor arrives at his conclusions, as figures alone occupy several pages. To decide the effect of light upon the increase of stem-volume, the needles from each tree were weighed, and the increase in volume during the previous five years measured. From these data the relation between needle-weight and wood-production is seen to be—

Stem 1—100 grammes produced	206 ccm.
" 2—100 " "	178 "
" 3—100 " "	169 "
" 4—100 " "	185 "
" 5—100 " "	170 "
" 6—100 " "	201 "

or on an average—

Stems 1—6 produced	181 ccm.
" 4—6 " "	187 "
" 1—6 " "	183 "

for each 100 grammes of needles, thus demonstrating that the same quantity (approximately) of dry substance was produced by the same weight of needles, in spite of the different development of individual trees. Dr. Ramann therefore concludes that "the influence of light cannot have caused the condition of the suppressed, and still less that of the dominant trees alone. One must conclude that sufficient light exists in normal Scots Pine plantations for the needles of suppressed trees to assimilate in a degree corresponding to their numbers." The nourishment of the stems with mineral food is then gone into, and the relation between the mineral-food obtained from the soil and the production of wood in the stem compared. The trees belonging to the "pole" stage contained the following percentage of ash:—

	With Needles.	Without Needles.
1. Predominant	569 per cent.	549 per cent.
2. Dominant	505 "	464 "
3. Suppressed	643 "	593 "

Those of the "thicket" stage:—

4. Predominant	711 per cent.	612 per cent.
5. Dominant	826 "	790 "
6. Suppressed	799 "	697 "

From the above figures it appears that no important differences exist in the mineral-food taken up by the various trees (the constituent elements being in proportion to the total ash). The figures also show the difference between the ash of the twenty years old and that of the thirty years old trees, and the stem analyses indicated that the development of the latter up to the twentieth year closely approached that of the former. This facilitates the question being answered, What quantity of mineral-food was taken up by the tree between the twentieth and thirtieth years, and how much organic substance was formed with its aid?

Only the proportion of wood by volume can be considered, as the necessary conditions for estimating its weight were wanting. It is therefore assumed that the ash contents of the thirty years old trees, when these had completed their twentieth year, bore the same proportion to the volume of wood then formed as the total ash bears to the total volume at the thirtieth year. According to this assumption, tables are given showing the quantities of lime, potash, phosphoric acid, and total ash in the three stems of the "pole" wood at the twentieth year, and also the quantities of these substances taken up between the twentieth and thirtieth years, both with

and without needles. According to these tables, the greatest increase or quantity of mineral constituents taken up was in the predominant tree, which doubled its ash during the ten years. The ash of the dominant tree increased by about 30 per cent., while that of the suppressed tree showed an actual reduction in ash-constituents, which is accounted for by loss of needles and branches during the period, proving that the quantity taken up must have been very small. Upon comparing the quantities gained by the first two stems, it is seen that 1 gramme of the different constituents is contained in the following quantities of wood:—

1 gramme of potash,	2,500 ccm.
in the predominant stem to each	1,821 "
" dominant	2,800 "
1 gramme of lime,	877 "
" predominant stem to each	2,800 "
" dominant	8,110 "
1 gramme of phosphoric acid,	9,783 "
" predominant stem to each	479 "
" dominant	692 "

With the exception of potash, the ash-constituents show a considerable falling off in the dominant stem. The fact that potash forms an exception is partly accounted for by the relatively high proportion of this substance in the soil of the district. Lime, on the other hand, is deficient, and the falling off in this substance is very marked.

The conclusions to which Dr. Ramann comes are: 1st, the quantity of needles on a suppressed tree produce, in proportion to their weight, the same quantity of wood as that produced by a tree in full possession of light; 2nd, the diminished growth of single stems is to be attributed in the first place to an insufficient absorption of mineral food.

The cause of these varied degrees of development may lie in the concurrence of vigorous growth, in individual capacity for food absorption, or in favourable or unfavourable influences to which the individual tree was exposed; and in Nature probably all three factors operate, sometimes one, sometimes another prevailing. If the above conclusions are correct, it may modify the theory, but scarcely the practice of thinning, which is always directed towards ensuring the survival of the strongest individuals. If a full supply of light has hitherto been regarded as the cause instead of the effect of the development of the latter, it cannot be regarded as of great practical importance, although of scientific interest. We know from practical experience that all species bear more shade on good than on poor soils, and this partly confirms the above conclusions, although investigations with other species may show different results. *A. C. Forbes*.

NURSERY NOTES.

MESSRS. W. CUTBUSH AND SONS.

For some years past it has been evident that the florists have well-nigh exhausted the capabilities of the *Hyacinth* for further improvement. During this time there has been a considerable number of new varieties introduced into our collections, but although the growers have succeeded in creating a wonderful multiplicity of named varieties, and in some instances they have added flowers with novel tints, there has been little progress manifested in respect to the size of scape and flower, or in the refinement of them.

In Messrs. Cutbush & Sons' collection, which a few days ago was very fresh and beautiful in the nursery at High Barnet, we found but one novelty included, and this notwithstanding (as Mr. W. Cutbush informed us) that most of the collections on the Continent were visited and examined last spring, with a view to securing any that were of surpassing merit. New ones there were, of course, but they are no better than existing varieties. The new one is named *Isabella*, and is a double flower, white, or in some instances inclined to assume the palest tint. The "bells" are extremely large, and we were disposed to admire it, for considering that the bulbs were young and of moderate size only, they had thrown very commendable spikes indeed. Still, it is

well known that double-flowering Hyacinths are now-a-days less popular than single ones, which are generally more reliable and more showy. The double flowers, nevertheless, are useful to the florist, and especially so in the case of such large "bells" as this new one has. The best of the older sorts were represented among the plants, and some of the best known are so perfect when well cultivated that it is not surprising that they are found difficult to excel. In the whites the more noticeable were *La Grandesse*, *Lady of the Lake*, *Madame Van der Hoop*, *albus maximus*, *Mont Blanc*; and of shaded or tinted varieties there are *Grandeur à Meryville*, *Anna Maria*, *Voltaire*, &c. Several yellow flowering varieties were noticed of the type of *Ida*, *King of Yellows*, *Van Vondel*, &c. Among the blue-flowered ones it is still difficult to select any that are better than *King of the Blues*, *Clas*, *Dickens*, *Grand Maître*, *Duke of Clarence*, *Czar Peter*, *Lord Derby*, *Queen of the Blues*, *Celestina*, *Lori Byron* and *Regulus*. Of the softer pink or rose-coloured flowers, *La Belle* is a very desirable variety. It usually

and large size. Prose-pine no doubt remains one of the best of the rose-caroline varieties; and *Keizerskroon* with its yellow and scarlet flowers, is one of most showy of all; *Joost Van Vondel* is a name that stands for a pure white flower, and for a crimson one with white base. Unfortunately, there are many instances among Hyacinths and Tulips where one name has been given to several varieties.

At *Barnet* one is very strongly reminded of the neglect that at the present day is shown to the beautiful hard-wooded Cape plants that used to form handsome features in most greenhouses. Messrs. Cutbush were among the last of the growers to give up the culture of these plants, which had been for years one of their specialties. However, as Mr. Cutbush remarked, "a nurseryman must grow what he can sell;" and in a great measure, the houses that were once filled with fine hard-wooded heaths, *Epacris*, *Pimelias*, and such like plants, are now devoted to other purposes. The soft-wooded Heaths and many of the *Acacias*, including *A. armata*,

FORCED ASPARAGUS.

I AM aware that little new can be said in regard to the forcing of Asparagus, and the following remarks mostly apply to forcing as carried out in permanent beds—an old plan, I saw advised in these pages many years ago. To force lifted roots is not a profitable business—in fact, in my owners of gardens have not sufficient land to grow it, and do not care to purchase the roots of the nurseryman to furnish a winter supply. It may be urged that a difficulty is found in obtaining Asparagus in useful quantity from permanent beds from the month of November. At that early period, however, it is advisable to begin to force Asparagus in period-beds in the open, unless flues or hot-water pipes can be used. To force this plant in the manner indicated, the beds must be specially made, and the plants receive special treatment, otherwise the returns in the shape of heads will be poor. My present remarks apply to the

FIG. 62.—A COMPLETED GRAFT: NEW STYLE. (SEE P. 199.)

FIG. 63.—METHOD OF GRAFTING RECOMMENDED: SHOWING THE GRAFT AFTER THE FIRST YEAR'S GROWTH. (SEE P. 199.)

flowers abundantly, producing a good scape of flowers. *Pink Perfection*, *Bella Donna*, and *Rosy Morn*, are also good. *Amy*, *King of the Belgians*, *Lord Macanlay*, *King of the Scarlets*, *Koh-i-noor*, *Princess Louise*, and *Queen of Naples*, are all deeper in colour, and belong to a very showy section.

Turning to the Tulips, the collection at *Barnet* is composed exclusively of known kinds. A number of these were to be seen in good sized batches of plants, with blooms but partially open.

Cottage Maid is a rosy-pink single flower, with a sort of white feather on the exterior of the segments; then there is a curiously flaked variety named *Standard Royal*; the well known *Potterbakker* can be had with scarlet, yellow, or white flowers. *Thomas Moore* is distinct, being terra cotta colour, mixed upon the exterior with scarlet; it has a fine globular form. *Vermilion Brilliant* is an early one—of very dazzling colour. Of yellow ones, there are *Chrysolora*, *Gannet Bird*, and *Yellow Prince*. The flowers of *Yellow Prince* are fragrant. One of the very best single early-flowering yellow Tulips is *Ophir d'Or*; it has golden-yellow flowers, the segments are long, and the blooms are of pretty form

A. Iophantha, *A. Drummondii*, *A. cordata*, and *A. Ricciana*, are still valued in gardens, and the *Boronias* also, such as *B. megastigma*, *B. elatior*, and *B. heterophylla*. All of these were noticed in some quantity.

In one house there were about 3000 young *Roses* of climbing varieties; they had been grafted in warmth since Christmas, and are now making growth. They will presently break again from the base of the present growth, and at the end of the season, plants so treated have usually made strong growths of about 14 feet long. They will be transferred at a later date from the 5-inch pots they are in at present, into others of 8 or 9 inches. *Turner's Crimson Rambler*, the climbing *Teas* and *Noisettes*, and others, are all successfully treated by this method of winter grafting. The *Cinerarias* and *Cyclamens*, especially the latter, will soon have passed, and the propagation of *Dahlia*s and other plants is being effected. Messrs. Cutbush's extremely fine collection of *Carnations*, which includes a large number of plants of the *Malmaison* varieties, is at *Highbate*, and the *Palus* and other decorative plants also. At *Barnet* considerable space is devoted to hardy trees and shrubs.

period] from January onward till the beds in the open afford supplies; and at this period forcing may be carried out at a small cost in labour and time, and the produce will be but little inferior to that of unforced roots. To supply a few early dishes of Asparagus, the roots are lifted and forced indoors, as our permanent beds are not heated by flues or hot-water pipes, and as lifting is not a profitable proceeding. The value to the grower of permanent beds for what may be termed a full, or at least a good supply, consists in being able to cut heads from the beds three or four times a week at a trifling outlay. For heating I use tree leaves, and in many gardens these can be obtained if diligently raked up as they fall, before they get blown into inaccessible places, and these leaves furnish a quantity of leaf mould in the course of two years or thereabouts.

At *Ston* there exists a series of Asparagus beds measuring 10 to 50 feet in length, and 1 foot in width, raised 2 feet from the level, with alleys of 3 feet in width between them. These alleys are 1 foot deep, and the beds are enclosed with 1½ inches thick brick-walls, pigeon-holed. In November these alleys have the half-decayed leaves cleared out, fresh leaves being

substituted for them; the latter are placed in a large heap to get compacted by fermentation before putting them in the alleys. It is necessary to make several additions, the first filling soon sinking, and each fresh lot is well trodden down and rammed as well, in order to make the whole as compact as possible. The alleys are filled towards the middle of December, the leaves then over-topping the beds a few inches. The fermenting leaves afford a mild, moist heat that does not unduly hasten the growth of the shoots, and these are succulent, and of greater edible length than shoots from hard-furred roots in hot-beds.

The beds must be covered, and formerly I made use of wooden-shutters covered with litter, but shutters are not really needed in mild weather, a thickness of a few inches of litter sufficing to keep the beds warm. In frosty weather the shutters are of much use, and ours are made of boards 15 inches wide, which are laid on the tops of the walls with cross-pieces laid on to keep them in place, and bracken or litter, and garden-weeds over all. The alleys are always kept quite filled with warm leaves, so that heat is communicated to the space above the soil of the beds. Cutting begins towards the end of the first month, that is about six weeks from the date when the beds are covered over completely, and it finishes when the beds in the open come into bearing. The beds at Sion have been forced for the last twenty years, and their productiveness is still very great, a fact that is due probably to the roots of the plants finding access to the decaying masses of leaves left in the alleys the summer through. The management of the beds after cutting leaves, includes the supply of an abundant quantity of water, the beds having, by their formation, perfect drainage, which have to be flooded with water in very hot weather; first allowing the land a good dressing of fish-manure or guano, and occasionally of salt. The soil of the garden being of a very light description needs a great deal of water, but heavy soils would require much less. If the leaves sink excessively in summer time, the beds are mulched with litter, but it is seldom needed if some of the soil is raked from the beds into the alleys when cutting has ceased; at that time a dressing of decayed cow-dung is applied. When Asparagus is forced every year, the roots begin to furnish heads with great regularity. I would advise the use of tree-leaves in preference to stable-dung, the heat being milder and more lasting. With fire-heat in any form the beds are liable to get too dry, and the application of water during the forcing is a necessity that cannot be avoided, whereas the use of leaves has no disadvantage unless it is its slowness as compared with other methods. *G. Wythes.*

THE WEEK'S WORK.

THE HARDY FRUIT GARDEN.

By H. W. WARR, Rayleigh, Essex.

Disbudbing Wall-trees.—Continue to disbud wall and other trees at short intervals of time, as recommended by me in the issue for March 13, and do this till all of the surplus buds have been rubbed off. By removing only a small percentage of the buds from trees at each operation, no check to growth is inflicted. The shape and fruitfulness of young trees are brought about by careful disbudding, by pinching the tips of over-vigorous shoots and forcing, and by arranging the shoots early in point of time, not wasting the energies of a tree by letting shoots attain a length of 3 or 4 inches before removing them, as is too often the case at this busy season.

Orchard-trees.—An examination should be made of all staked trees, making loose ones firm in the ground and all ties secure, especial care being taken to placing a pad of leather, straw or cloth between the bark and the stake, yet not making the ligature so tight that it will cut into the bark before it will want renewing. The same remarks apply to the securing of the branches of espalier-trees.

Raspberry Canes.—If the operation of tying the canes has been so long delayed, no time should now be lost in getting it done. Allow a distance of 6 inches between the canes in tying them to the wires with bands of raffia, in the case of canes of annual-bearing Raspberries, which were cut down to the ground early in February. The young growths resulting from the cutting down of last year's canes will now require to be thinned to 5 or 6 inches from one another in the rows, in order to secure strong canes for fruiting from July onwards till cut down by frosts. As the young canes grow they should be tied

to two stout strings twisted round a series of stiffish sticks stuck into the ground at short intervals in the rows.

Protecting Materials.—The various blinds, &c. in use for the protection of the fruit blossom from frost should be let down over the trees when frost is apprehended, not otherwise, as if let down during fairly warm nights, when the thermometer registers several degrees above the freezing-point, aphids is sure to effect a lodgment on the trees.

Vines on Walls.—If these Vines have been treated as recommended in the *Gardeners' Chronicle*, on p. 123, February 20, all the buds excepting one should be rubbed off each spur or eye to which last year's shoots were pruned back, retaining, as a matter of course, the one that is the most promising. This will produce this year's fruit. When the bunches show, leave, so far as can then be judged, the largest-framed and best-formed on each shoot. Later on, when the bunches have set their berries, and the best to constitute the crop can be definitely determined, it will be necessary to make a further reduction in the number of the bunches. In Vine-culture, the size and strength of the Vine, as well as the kind of soil, situation, and climate, have all to be considered.

THE FLOWER GARDEN.

By CHARLES HERRIN, Gardener, Drogheda, Maidenhead.

Rhododendrons and other American Plants.—These plants may be moved with almost perfect safety now or during the next few weeks. Late planting is not advisable, but I have transplanted Rhododendrons from one part of an estate to another until the middle of May. The recent rains will have thoroughly soaked the soil about the roots, and thus the conditions necessary for transplanting now exist. Where the natural soil consists of a heavy clay, or contains much lime, make-up beds become a necessity. These need not be composed of peat, as both Rhododendrons and Azaleas will grow and flower freely in a compost of sandy loam and leaf-soil; and if peat be not available, sandy loam and half-rotten leaves in equal proportions will prove a good substitute. These plants root chiefly near the surface, and the beds of prepared soil need be but shallow, say, 4 or 5 inches, but the subsoil should be porous, for they require an abundance of moisture, and if this does not drain away quickly the plants do not succeed. Make the plants quite firm in the soil, and then afford a good mulching of leaf-mould, and one thorough soaking of water to settle the soil about the roots. A sheltered site should be selected for hybrids of the Nobleman type, and other early-flowering varieties. If these be partially sheltered by deciduous trees, and screened by evergreen shrubs, they will afford valuable blossoms in most years. Should frost threaten when the plants are about to flower, cut any with buds just showing colour, and they will open in a few days if placed in water in a warm room. Hardy Azaleas of the Ghent and pontica sections are excellent companions to Rhododendrons, and require similar treatment. Besides possessing pink, crimson, and yellow flowers in many shades, they are also decidedly sweet-scented. *Ledum latifolium*, *Perpetuas*, *Kalmias*, and *Vacciniums* may also be transplanted now.

Water Lilies.—The introduction of the fine varieties of *Nymphaea* raised by M. Latour-Marillac has caused more attention to be directed to this style of water gardening. They should be planted from the present time throughout April, or until growth commences. The most suitable situation is a lake, or pond, where the water is from 2 to 4 feet deep, with 6 inches or more of mud at the bottom, but I have seen them doing well where there were only 18 inches, or even less water. The best method of cultivation is to plant the tubers in shallow baskets or tubs, and to hold about a bushel of soil, and use good fibrous loam, broken moderately fine, and leaf-soil in nearly equal proportions. When planted, tie them down to the basket to prevent the plants being pulled out or disturbed by swans, or other means; and before sinking the basket in the pond, lay a few stones on the surface of the soil. Where the water is shallow, small baskets or large punnets may be used in which to plant the Lili-tubers. The following are good varieties to plant:—*N. Martiana carnea*, *N. M. rosea*, *N. M. albida*, *N. M. chrysantha*, *N. L. Leyleke*, *N. M. (of more slender growth than the other varieties)*, *N. L. purpurea*, *N. odorata sulphurea*. The common white Water Lily, *N. alba*, is also worth planting, and will grow almost anywhere.

THE KITCHEN GARDEN.

By W. FARR, Gardener, Highclere Castle, Newbury.

Kidney Beans.—Seed may now be sown in quantity either in pots or cutting-boxes, if these are 6 to 8 inches in depth, for the production of pods in the months of May and early June. This sowing will not need to be grown in a hot-house after germination, which should take place in heat of 60° to 65°, but they may be placed in any cold-pit or frame that may be available about the end of next month, advantage being taken to forward growth by closing the lights soon after midday, by allowing the warmth in the frame, with air given, to reach 70°, and by covering the glass at night more or less, according to the outside temperature. As fast as the frames are cleared of the early Potatoes, &c., the soil should be levelled, and Kidney Beans sown. *Ne Plus Ultra* being one of the best for the purpose, being of dwarf, compact growth, and a heavy cropper. Plants now in bearing should receive copious supplies of weak liquid-manure twice a week, and be syringed daily with clear soft-water. The soil for Beans in pots should be rich, light, and be warmed before being used in potting them. No Kidney Bean should be grown in a fruit-house, if it can be avoided, or remain in any house after a crop is gathered, or red-spider will soon spread from the plants to others in the house.

Peas under Glass, &c.—Peas which are being forwarded under glass should be afforded weak liquid manure occasionally, and ventilated freely in the warm part of the day, closing the lights in good time, and if standing in frames covering the lights on cold nights. Plants being forwarded under glass for planting outside should be planted without further delay, or they will be no earlier than the first outdoor sowings. If the land be heavy, leaf-soil should be worked in round about the roots in planting them. As soon as planted, dust the plants with fresh soot, and put the sticks to them. The early sowings now coming up must be protected from the ravages of birds and mice. Against the birds use black thread stretched in intercrossed lines just above the soil, and for the latter use traps; and let the rows be mounded up when the plants are a few inches high. When sowing the main-crop Peas, it is advisable to wet the seeds and roll them in red lead powder.

Seakale.—Seakale may at this season be easily blanched where it grows, by placing sifted coal-ashes over the crowns about 9 inches or 1 foot deep, so as to shut out the light. Shoots obtained in this manner are of excellent quality.

Vegetable Marrows.—If Vegetable Marrows are to be forced under glass, seed should be sown forthwith on a mild hot-bed, and preferably where the plants are to grow and fruit. When up, allow the plants all the light possible; afford air freely from the first on all favourable occasions, taking care, however, to protect the plants from cold winds at all times, shutting up the frames early in the afternoon, and covering them securely at night for the present.

PLANTS UNDER GLASS.

By G. H. MACOCK, Gardener, Luton Ho Park, Luton.

Boundarvias.—The young plants that were struck from cuttings taken from selected old plants which were dried off in October, and then pruned back so as to furnish suitable shoots for the purpose in the winter, will now, if they are kept fairly moist, move freely. It will be necessary to nip the points of the shoots to induce bushiness; and to keep the plants in active growth, a warmth of 65° to 70° by night, and 10° more by day, should be maintained, affording them a slight amount of shade during the hottest hours of the day. Slips with a heel, and small pieces of the roots, will strike at the present season when placed in bottom-heat of 75° to 80°; but late autumn or winter-struck plants give the better results, and make finer plants in the shortest period of time.

Cyclamens from Seed, if pricked off into pans, will probably now require to be potted into thumb-pots, taking care in doing so to place the corn to only half its depth in the soil. Place the potted seedlings on a bed or solid stage (not shelves) near the glass, in a moist warm-house or pit.

The *Taberna* (*Polyanthes tuberosa*).—Some of the best should now be potted in a mixture of three parts partially-decayed turfy loam and one of leaf-mould, with a small amount of sharp sand. I prefer to pot the bulbs in the spring; but if sown at the first, they need not be bigger than large 18's. If any of the bulbs exhibit signs of decay, the affected parts should be cut clean away, and the bulbs strewed

with or rolled in charcoal powder and lime. In potting, the bulbs should be buried to one-half their depth, and firmly potted. One bulb in a pot is enough; and the soil should neither be too wet or too dry. Plunge the pots in a bed of coal-ashes, with a cold frame over it, introducing them to the forcing-house as may be required. The forcing must be very gradual, no water should be afforded before the flower-spikes push up, unless the soil should get very dry, but afterwards water when necessary, as with other plants, affording liquid-manure if the spikes appear weakly, and syringing frequently in order to prevent infestation of the leaves by red-spider. By following out this course, a continuous supply of flowers can be obtained from the month of August until the end of the year.

Agathae cœlestis.—A good stock of cuttings of this plant may now be struck in a cool-house under a hand-light or bell-glass, the rooted cuttings being potted without delay. It is a plant that flowers best when the roots are somewhat pot-bound. The potting soil should be chiefly fibrous loam, and 4's are sufficiently large pots to flower them in. Grow them in a cold frame during the summer, removing them in the autumn to a house with a temperature of 50° by night and 55° by day. The plants will require stopping once or twice in the early stages, but beyond keeping green-fly in check, it is an easily cultivated subject. For supplying a profusion of blue flowers during the autumn and winter months, when blue flowers are scarce, this *Agathae* should not be neglected.

General Remarks.—See that Marguerites do not get over-run with the meagrot, and as the grubs that are bred are to be mined in the leaves, should be nipped with the thumb-nail. Sow seed of Nigouette in pots in loam which has been stacked for not less time than nine months. Plants of *Reinwardtia* (*Litum*) *trigynum* and *Libonia floribunda* which have flowered should now have their shoots cut in severely, and be placed in such a position that strong, healthy growth be made. Cuttings may be taken when the shoots have grown to a few inches in length.

THE ORCHID HOUSES.

By W. H. WHITE, ORCHID GROWER, BURFORD, DORSET.

Incidentous Calanthes.—The species and hybrids of this genus are exceedingly beautiful, and useful for decorative purposes. Unfortunately, near large towns there are usually fogs prevalent at the season when the plants commence to bloom, which sometimes destroy the inflorescence. To commence the cultivation of these *Calanthes*, the following hybrids would form a useful and pleasing collection:—*C. Veitchii*, *C. V. alta*, *C. Sedoni*, *C. Bella*, *C. Harrisii*, *C. Halli*, *C. Victoria Regina*, *C. Burfordiense*, *C. Bryan*, *C. William Murray*, *C. versicolor*, *C. perlyraea*, and the varieties of *C. vestita*, as *C. Turneri*, *C. T. nivalis*, *C. rubro-oculata*, and *C. luteo-oculata*. *Calanthe* (*Limatodes*) *rosa* is a distinct and charming species, well worth growing. The means of raising them will be repeated below when roots are made. Shake out the exhausted soil, and shorten the roots to about 1 inch. The part left is necessary to keep the pseudo-bulbs firm until they are established. The soil should consist of one-half tuff yellow loam, one-fourth fine chemp, or well-decayed leaf-soil, and one-fourth cow-dunged sphagnum-moss, small crocks, and coarse silver-sand. Half-fill the pots with drainage, and over this place a thin layer of loamy turf, with the grass-side downwards. When potting, shake the soil down moderately, firmly, and to the base of the pseudo-bulbs, to within half an inch of the rim of the pot, this will leave sufficient space for a top-dressing of fibrous loam when the plants are in active growth. The usual practice is to plant the pseudo-bulbs singly, but where house-room is limited, several may advantageously be planted together in pots of a suitable size. The plants require the lightest and best position in the East Indian-house, or they may be successfully cultivated in the plant-stove, Pine-pit, or Cucumber-house. Give no water at the root until the plants have been potted into their vessels, but merely syringe between the pots several times a day, according to the state of the weather. When the new growths have begun to grow freely, slightly sprinkle the soil with water by means of a fine rose watering-can, but even then the beginner must use much discretion; for if the soil be made too wet by dipping or watering, the tips of the young roots decay, and the health of the plant becomes impaired. When the roots have a firm hold of the sides of the pot, water may be given less hesitatingly, and when thoroughly well established an abundance of water should be alternated with weak liquid cow-manure.

The stock of any particular variety may be increased by taking off the old back bulbs previous to their potting, and inserting them close together in pots or shallow pans filled with sphagnum-moss, but affording no water. Place them in a light position, and when the bulbs commence to grow, re-pot them singly, as previously advised. Seedlings from last spring may be potted off now. The best method is to place several around the edge of the smallest-sized pots, and suspend them from the roof of the house. They will receive the same kind of treatment as the older plants. Any of the latter that are bearing seed-spikes should not now be disturbed by repotting; but be placed in full sunshine to mature and ripen the seed. Immediately the pods burst, carefully wrap a piece of tissue-paper around them to prevent loss of seed, and when the old stems commence to die down, cut them off. By that time the plants we are now potting will have made many roots, and upon those which have the greatest number of roots the seed should be sown. It usually germinates in a few months, and until this takes place those plants must be watered. When the seedlings are up, and have made some roots, they should be kept moist, but they must not be disturbed before next spring. *Calanthe Regnierii*, and its varieties *Sanderiana*, *Williamsii*, and *Stevensii* will now be in bloom; these also will require repotting after the spikes are cut and growth has recommenced. This section of the *Calanthes* is more serviceable to those who, for reasons stated above, fall to grow the early winter-flowering varieties satisfactorily.

Phyllitis cynosuroides and *E. conopsea* have started to grow, and may be repotted. Give them the same treatment as the *Calanthes*, in regard to potting, watering, and resting, but when growing they should have rather more shade.

THE APIARY.

By EXPERT.

Weather and the Bees.—While not exceptionally unseasonable, the weather keeps dull and cloudy, cold winds confining bees within doors, except on the odd days when sunshine warms them into activity and eagerness to get a fly abroad. One can easily understand the great amount of good done to a full colony of bees when a real "flying day" occurs for the first time in spring after several months of inactivity. Essentially an outdoor worker, the open air and sunshine is life to the bee in far more senses than to the majority of insects. Nor does anything afford more genuine enjoyment to the true bee-man than to see the "turn-out" of strong stocks when they do get their first real flying day in spring, and show him that they have not forgotten how to scent pollen, and bring it home.

Contracting the Hives.—Although we advise no stimulating this month, the weather may be quite warm enough towards its close to warrant a full examination of the brood-nest, and a consequent crowding of the bees on fewer combs for the sake of warmth. Empty space below the combs may now be dispensed with.

Uniting Queenless Bees.—Where stocks are ascertained beyond doubt to be queenless, the bees should be added to the next stock as follows: Bring the two hives as close together as they can conveniently be placed by gradually lessening the distance between them a yard or so daily. Smoke the bees slightly, and sprinkle both lots with thin syrup, then remove an outside frame from the hive which is to receive the queenless bees, and substitute one from the last-named with the adhering bees in its stead; pour a little syrup in between the combs, and give more smoke as the frames are placed together, and proceed as before till the bees of both stocks are joined together in one hive. Examine carefully to see that no frames containing brood or eggs are removed from the hive where the queen is. If the space has been properly contracted by division boards, the removal of these give the required room for added frames.

Stimulating.—This is often started nearly a month too early, and much mischief has been caused thereby. When the bees are well off for food, they are best left alone until plenty of mature pollen can be had. Of course the resources of the neighbourhood will be taken into account; but where a natural supply exists, we do not like to forestall that supply by artificial means, it is wisest to let nature and the season guide us. Stimulating is useful enough if judiciously begun and carefully continued, but it has been misunderstood and terribly abused in times past, principally, as we think, by beginning too early, and in some cases by carelessness and neglect afterwards. Many also imagine that syrup alone will cause queens

to commence egg laying—in this is a mistake; unless pollen be already in the hive, or is obtainable in other ways, stimulating is only half accomplished, and no start is made. Whenever brood is being raised, pollen will invariably be seen in the cells of the opposite comb ready for the nurse-bees' use, we thus know for certain that the larvae require uterogenous food as well as honey; and in localities where pollen is scarce, it becomes necessary to fall back upon such substitutes as we know of. The time to begin stimulating must be regulated by two things—first, the earliness of the district in which bees are kept; and second, by the season. In plain words, when bees are carrying in pollen freely, supplement this by giving syrup slowly and regularly (not by fits and starts), or by uncaping sealed food at intervals of a few days, but do not expose brood or uncoveer hives oftener than is absolutely necessary. It must not be supposed that stocks which are working vigorously may be left to take care of themselves henceforward, their very prosperity now may be the cause of disaster later on, if the rapidly increasing population should exhaust the stock of food in store, and the bee-keeper does not take care of the "cupboard" by guarding against famine.

FRUITS UNDER GLASS.

By F. HARRIS, GARDENER, EASTON CASTLE, LEDBURY.

Cucumbers.—Those recently planted now making rapid progress should have the lateral shoots constantly nipped at the joints, and the main shoots, as well as the longer laterals, evenly distributed without crowding them, and be tied loosely to the trellis, supporting the plants as they grow in houses. In ordinary pits and frames the same kind of treatment is required, but instead of tying the bine, it must be kept in place by means of wooden hooks, or bits of brick or stone. The laterals should be stopped one leaf in advance of a fruit. Top-dress with fibrous loam, old mortar, some fresh horse-droppings, and one handful of soot per bushel of soil, affording a temperature of 85°. Plants in bearing should occasionally be afforded liquid-manure. Do not preserve old plants whose best time is over, but clear them out, whitewash the pit, and clean the glass, put in new hillocks of soil, and start with vigorous young plants. If old, and they must be retained for a short time, thin out the old leaves, taking in preference all of those which are mildewed, or infested with thrips or red-spider, syringing those that are left with soap-suds and flowers-of-sulphur; top-dress the bed, and apply manure-water. New growth will soon push in sufficient quantity to cover the trellis anew, and furnish Cucumbers till the young plants come into bearing. Sow Cucumbers-seeds occasionally.

Strawberries.—Plants which have fruited, if required for planting out, should be placed in a cold-frame, and gradually inured to the outside air; when planted out on a warm border good fruits are obtained from such plants late in the autumn. When removing them from the forcing-house, see that the soil is thoroughly moistened. Strawberry plants carrying ripe fruit should be afforded air freely, and if the fruit is not wanted for a few days, remove the plants to a cool, dry house, and shade from strong sunshine. The fruit will not keep for a longer period than one week. Successional plants must be kept gently moving, affording weak stimulants to those growing in small pots, which have set twelve to eighteen fruits each. When thinning the fruits on late successions, remove more than is the rule with the earlier batches. As soon as things get a little colder, attend the fruits to prevent the stalks from bending over.

Tomatoes.—Those plants which are carrying fruit now swelling fast should be afforded liquid-manure once or twice a week, but plants that have not set much fruit will be the better for being kept rather dry at the root, and not stimulated with manure. When Tomatoes are planted in large pots, or their roots have the run of a large mass of soil, the growth is very strong, and as a consequence they set badly; but if the plants are firmly potted in smallish pots and kept a little dryer, this tendency is overcome. The lateral shoots should be pinched out, and the tips of the leaves removed if very luxuriant. Attend the plants more air as the sun-heat increases, which will have the effect of facilitating fruit-setting. Succession plants should be repotted before the roots get pot-bound, giving two or more shifts till they come into their fruiting pots. I prepare the plants by getting them into their fruiting sizes as fast as may be, standing them in light places in vinerias and other forcing houses. See that the plants for outdoor fruiting are potted, staked, and kept in good condition, and not starved in small pots.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturalists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, MAR. 27	Royal Botanic Soc. Meet.
WEDNESDAY, MAR. 31	Royal Bot. Soc., Spring Exhibition.
THURSDAY, APRIL 1	Linnean Society. Royal Hort. Soc. of Ireland—Spring Show.
SALES.	
MONDAY, MAR. 29	Tuberose, Cannas, Carnations, Begonias, &c., at Protheroe & Morris' Rooms.
TUESDAY, MAR. 30	Asters, Anemones, Tigridias, Roses, Imported and Established Orchids, &c., at Protheroe & Morris' Rooms. Border Plants, Roses, Shrubs, Bulbs, Lilies, at Stevens' Rooms.
WEDNESDAY, MAR. 31	Japanese Lilies, Carnations, Azaleas, Roses, Heliconias Plants, &c., at Protheroe & Morris' Rooms. Great Sale of Roses, Edibles, Fruit Trees, Ornamental Shrubs, Lilies, &c., at Stevens' Rooms.
THURSDAY, APRIL 1	Special Sale of Border Plants, Lilies, Bulbs, Roses, &c., at Stevens' Rooms.
FRIDAY, APRIL 2	Imported and Established Orchids, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—45.39.

LOCAL TEMPERATURES:—

LONDON.—*March 24*: Max., 62°; Min., 49°.
PROVINCES.—*March 24*: Max., 55°, Yarmouth; Min., 44°, Southam Head.

TESTIMONIALS are now often such matters of course, got up for every conceivable purpose, with little or no discrimination, that many of them are looked on by subscribing victims as a species of blackmail, and the whole system is apt to inspire loathing. Of course, we are alluding to some and not all public testimonials. For some there is ample justification; while in the case of those which are kept private we have, of course, no right to raise any objection at all.

In the case of our late friend Dr. HOGG, it may be known to some of our readers that an attempt was made, shortly before his death, to collect together in a handsome Album a series of portraits of his old associates and colleagues. About a hundred portraits were thus received (comprising most of the representative men), and the number might doubtless have been much increased, but for the system of selection adopted. Unfortunately, the delays in the preparation of the Album were such, that the finished volume only appeared on our table shortly after the decease of the great pomologist. The secret was well kept till nearly the end, when, foreseeing the probable issue of the case, the nature of the proposed gift was made known to the intended recipient. There is at least reason to believe that some of our friend's last anxious hours were rendered pleasant by the intelligence conveyed to him.

It is impossible not to feel sorry at the painful frustration of a plan which excited universal sympathy, but we could not have done otherwise under the circumstances. For the future, we have the satisfaction of knowing that the Album now becomes the property of Mr. R.

MILLIGAN HOGG, the only son and the present editor of the *Journal of Horticulture*. To him it will come as a pious souvenir of the past, and a great encouragement for the future.

And now we make way for another old friend, whose proposal we doubt not will be warmly received:—

"Grand as the exhibitions of fruit often are at the present time, the Royal Horticultural Society has no special medal to offer as the highest award for fruit. It has its Flora, its Baukasia, Veitch, &c., but no special fruit medal. May I, therefore, suggest this. Is there not now unusual and highly fitting opportunity to have such medal, and let it be in the honour of the one whom to know was to love, and to associate with was indeed a privilege.

"Let, then, a subscription list be opened that we, by giving, may thus testify our regard and high estimation and deep sense of our appreciation of the valuable contributions to all that appertains to the better understanding of our fruits, our fruit trees, and their varieties. Let the fund thus raised be to found a medal or medals to be annually awarded or otherwise for fruit excellence in exhibition only, and that such medal be entitled 'The Robert Hogg Fruit Medal.' If this can be done, as indeed it should, I for one shall be most willing to give my mite, though but a poor token of a life-long admiration of the man and his work. *Harrison Weir, Screenooks.*"

Our readers will find on p. 210 in the report of the Royal Horticultural Society's meeting of Tuesday last, an eulogistic estimate of the late R. HOGG, addressed by the Rev. W. WILKS to the assembled members of the Fruit Committee.

We have already alluded to the successful results consequent on a Commission of inquiry, of which Prof. SARGENT was a member. We have now before us the full text of the letter of the Secretary of the Interior to the President (CLEVELAND), transmitting a report by the National Forestry Commission to the National Academy of Sciences, recommending the establishment of additional forest reservations. We have not space to enter into detail, but we may say that in addition to previous reserves, the President has now sanctioned the reserve of no fewer than 21,379,840 acres, mostly in the Central and Western States. Thus the conservation of forests of untold value, till now in danger of extirpation, has been secured, to the enormous advantage of the country, economically and climatically:—

"The total area of the reservations hereby proposed," says the secretary, "exceeds that of all those heretofore established by about 4,000,000 acres, but as our public forests are being rapidly denuded, and the loss resulting therefrom is incalculable, I do not think this apparently large area should militate in any degree against the recommendation of the commission.

"I respectfully suggest that the one hundred and sixty-fifth anniversary (February 22, 1897) of the birth of the father of our country could be no more appropriately commemorated than by the promulgation by yourself of proclamations establishing these grand forest reservations."

Of each of the thirteen Reserves a short account is given, from which we take the following by way of illustration:—

"3. The Teton Forest Reserve.

"This proposed reserve embraces 829,440 acres, and is south of and adjacent to the Yellowstone Park Timber Land Reserve. The forests which cover it are similar in character to those in the Yellowstone National Park; they are capable of supplying all local demands that will probably ever be made on them, but have little commercial value. This proposed reserve contains the Teton Range of mountains

and Jackson Lake, and some of the grandest and most picturesque scenery of the Rocky Mountains. Within its borders are many streams flowing west, south, and north, and as a reservoir of moisture it is important. Incidentally, it may be mentioned that the proposed reserve is a favourite home of the elk and other large game, and that as a game reserve it would well supplement the Yellowstone National Park and the Yellowstone Park Timber Land Reserve.

"9. The Olympic Forest Reserve.

"This proposed reserve occupies the high and broken Olympic Mountain region in north-western Washington, and contains an estimated area of 2,188,500 acres. This is a region of steep and jagged mountains, their highest peaks clothed with glaciers and with perpetual snow. The forests here, watered by more copious rains than fall on any other part of the United States, are composed of enormous Spruces, Firs, and Cedars, and in productiveness are surpassed in the world only by the Red-wood forests of the Californian coast region. Few explorers have penetrated far into this region, which from the denseness of its forest-covering, offers exceptional difficulties to travel; and there is no record that it has been crossed in a north to south direction. This proposed reserve, no doubt, contains for its area the largest and most valuable body of timber belonging to the nation; and here is probably the only part of the United States where the forest, unmarked by fire or the axe, still exists over a great area in its primeval splendor.

"The character of its forests, which can be made to yield permanently vast quantities of timber, its wildness, the picturesque quality of its surface, and its remoteness, make the proposed Olympic reserve one of the most valuable of all the forest reserves which have been made or proposed."

"The commission is now engaged in perfecting a scheme of forest management which it believes will make the administration of the reserves possible, and which in due time will be submitted to you. It believes that the solution of this difficult problem will, however, be made easier if reserved areas are now increased, as the greater the number of people interested in drawing supplies from the reserved territory, or in mining in them, the greater will be the pressure on Congress to enact laws permitting their proper administration. For this reason it is the unanimous opinion of the commission that the establishment, by proclamation, of the reserves described above is now a matter of the utmost importance to the development and welfare of the whole country."

The attainment of this end has been one of the main objects of Professor SARGENT's labours for many years. He may be congratulated on his success, for greater service to his country it would be difficult to render.

TREE FERNS AT MENABILITY.—This well-known Cornish garden, belonging to JOHN RASHLEIGH, Esq., has frequently furnished materials illustrating the successful cultivation of plants coming from warmer regions than our own, especially those of New Zealand, South Australia, and Japan. Our illustration (fig. 64), taken from a photograph by Mr. RASHLEIGH himself, represents a group of Tree Ferns growing in a sheltered spot in the pleasure grounds at Menability. The largest, 8 feet high, came from Kew about five years ago, at which time its weight was 14 cwt., and height of stem 8 feet. The seven others came from Sydney rather more than two years ago, and they are 8 feet high. These plants, Mr. RASHLEIGH tells us, are kept in good condition by daily syringing the trunks in dry weather. In rainy or dull weather they take care of themselves.

LINNEAN SOCIETY.—On the occasion of the meeting on Thursday, April 1, 1897, at 8 P.M., papers will be read:—1. "On the Evolution of Oxygen from Coloured Bacteria," by A. J. EWART, B.Sc., Ph.D. 11. "On the Germination of Spores of Agaricoreæ," by Miss HELEN BEATRIX POTTER.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—We understand that the net proceeds from the performance of the comedy-opera "Dorothy," recently given in aid of the Victorian Era Fund, amounted to £60 2s. 3d., and a cheque for that sum has been forwarded to the Secretary of the Institution by Mr. H. MORRIS VETICH.

THE HAMBURG EXHIBITION.—One of the attractions will be a work by M. SCHUBERTSCHE, for which a special position will be chosen, and which will take the form of a series of representations by means of plants and paintings of the various floras of the globe.

of £150 in one series, exclusive of gold and silver medals, are open to gardeners and amateurs only. Other liberal prizes are offered to the trade.

CAPE FRUIT.—The Union Company's steamer, *Taylor*, has arrived from the Cape of Good Hope with the following consignment of fruit, viz.:—To Mr. G. E. HUDSON, 289 cases of Grapes; 150 do., to Mr. NATHAN; 34 cases of Grapes and 12 of Pears to Messrs. WOODHEAD, PLANT & Co.; and 100 cases of Grapes to the Colonial Consignment and Distributing Co. (Ld.); and most of the fruit turned out in excellent condition.

RELIQUIÆ MUELLERIANÆ.—It seems that Mr. J. G. LUEHMANN, who rendered so much valuable service to the Baron, has taken upon himself to continue the publication of leaflets descriptive of new plants, in the same way as that carried on by the indefatigable VON MUELLER.

MR. HENRY STEVENS AS A PHOTOGRAPHER.—The proprietors of the *Graphic* have recently conducted an amateur photographic competition. Exhibits from all parts of the world have been received, and the competitors, it is said, numbered several thousands each of them being permitted to send six

FIG. 64.—TREE FERNS AT MENAVELLY, CORNWALL. (SEE P. 204.)

Thus, a moor, a Norwegian fiord, with a pine (Scandinavian) plants, and a Mexican view, with gigantic Caeti, are already completed, and other scenes are in preparation.

COMING EVENTS CASTING THEIR SHADOWS BEFORE.—One of the greatest of these promises to be that of the Edinburgh Chrysanthemum Society's show. It has already launched its Diamond Jubilee Schedule for November 18, 19, and 20, and offers prizes as follows:—1st, of £50 and a Gold Victorian Medal; 2nd, of £30 and a Silver Medal; 3rd, of £15; 4th, of £10; 5th, of £5; 6th, of £3. For twenty vases of twenty varieties of three blooms each, Chrysanthemum foliage only to be used, these special Diamond Jubilee prizes amounting to a sum

THE RECENT GALE.—It has been ascertained (remarks the *Daily Chronicle* of the 16th inst.) that during the recent gales on the south coast immense damage was done to the timber on the neighbouring estates of the Duke of Norfolk and the Duke of Richmond. It is estimated that the former lost quite 1000 trees, involving a great expense for clearing; whilst the Goodwood demesne suffered to a not less extent. The Duke of Richmond was specially grieved at the uprooting of eleven of his fine Cedars of Lebanon, part of the remnant of the 100 of those trees planted in and around Goodwood Park by CHARLES, the third duke, in 1760. There is to be an extensive planting of Cedars in the park and pleasure-grounds in commemoration of the Diamond Jubilee year.

photographs. The result has just been made known, and horticulturists will be interested to note that the first prize of £20 has been awarded to Mr. H. STEVENS, the well-known auctioneer. His photograph was entitled "Worn Out," and represents an aged woman in a worn-out donkey-cart. Mr. STEVENS is a frequent exhibitor of photographs, for which he has won many medals, but his latest success he is most proud of.

THE PENETRATION OF FROST INTO THE GROUND.—According to the researches of a French savant into the subject of earth penetration by frost, it makes a difference whether the earth be bare or covered with turf, in the former case, the penetration of the frost is much easier, quicker,

and deeper than in the latter, the layer of turf making an average difference of 50 centimètres in the amount of penetration. During the hardest frosts of 1896 it was observed that the frost penetrated the bare earth to a depth of 75 cm., whilst under turf the depth was about 50 cm. In the case of the former the frost in the first two or three days reached to a depth of 18 cm., whereas in earth covered with turf nineteen days of an average amount of frost of —1 Réau. (9° Fahr.) were required to show a trace of penetration at 5 cm. The continuous penetration of frost by night, and of sunheat by day, was likewise closely observed. It would be interesting to ascertain, in view of these statements, whether the protective layer of turf above the root of trees and shrubs retards or hastens growth.

WOOLTON GARDENERS' SOCIETY.—The last meeting of the session was held on the 18th inst., the Rev. GEORGE BEAUMONT presiding. There was an exhibition of plants and flowers, together with social amusements. Several groups of plants of a high character were shown. The attendance was most satisfactory, and a balance of £3 is to be given to the Victorian Era Fund.

THE CULTURE OF VEGETABLES.—Mr. E. KEMP TOOGOOD of Southampton has published a small pamphlet on this subject. It is intended for practical gardeners, and for them will be of much value; but we suggest to the reader that the preface be skipped, and that attention be paid simply to the practical directions, which are excellent.

HOOKE'S "ICONES PLANTARUM."—The February part (constituting the last part of the twenty-sixth volume), contains numerous descriptions and illustrations of plants of botanic interest contained in the Kew herbarium. A large series of species of *Eryngium* is figured and described by Mr. W. B. HEMBLEY. *Echinops bromeliifolius*, with linear leaves closely beset with spines at the margin, and furnished with cylindrical racemes of flowers, is a very extraordinary plant found in East Tropical Africa by Mr. SCOTT ELLIOT.

THE DOUGLAS FIR.—In the February number of the *Erythica*, Mr. J. G. LEMMON has revived an old name of KAFINESQUE'S, namely, *Abies mucronata*. The name was given in 1832, but was never taken up, and as the plant is not an *Abies*, it would have been better to have consigned it to oblivion. Mr. LEMMON, however, thinks otherwise, and calls the tree *Pseudo-tsuga mucronata*, Sudworth. Mr. SUDWORTH having, as we suppose, had nothing whatever to do either with the genus or the species! The result is a list of nine synonyms, the latest dating from 1895, besides others from European literature which are passed over. The gardener who speaks of the '*Douglas Fir*' is much happier!

APPLE CULTURE AND CIDER-MAKING.—With a view of obtaining accurate information, some of our Kentish friends are proposing to map out the fruit-growing portions of the county, parish by parish, and to report on the condition of the orchards. Prof. HALL, of Wye Agricultural College, is grafting his stocks with cider sorts from the West, and is arranging the holding of a cider conference in May. Cider-making involves considerable extra outlay, and is, except in two or three favoured localities, still in the experimental stage. Still, we can see no reason why, if made on scientific principles, and not "anyhow," it should not become remunerative, and a great boon to those consumers to whom malt liquor is objectionable. There is also no reason why the more modern bush culture of select Apples, cultivated and marketed on business principles, should not be combined with cider-making.

PLEASANT FOR THE BRITISH FARMER.—The steamboat called the *Ruba* has been lately put on the service between Antwerp and London, and is to be followed by the *Topaz* and the *Sapphire*. Any package of poultry, fruit, eggs, vegetables, &c., consigned to a Belgian station before 8 A.M. is delivered the next morning in the London markets at 5 A.M.

THE BRITISH MOSS-FLORA.—By R. BRATHWAITE, M.D., &c. The November part (xvii.) of this valuable publication treats of Fam. xix., Hypnaceæ i. Having on previous occasions called attention to the excellence of this work, it only remains to add that the quality of the letterpress and the accuracy of the illustrations are quite up to the usual standard.

POISON IN SPINACH.—Under the name of atropinism, or intoxication from Spinach (*Atriplex*), M. MATIGNON, physician to the French Legation at Peking, describes the ill effects which he has frequently observed among Chinese of the poorest class, particularly among beggars, and especially among the women. These ill effects are consequent upon the ingestion of young shoots of a certain variety of *Atriplex*, and are characterised by general swelling of the face, hands, and forearms, by sensitiveness, dilateness of movement, and circulation; and, particularly, by cutaneous disturbances, often complicated by ulcers more or less spreading over the swollen parts. M. LAVERAN has remarked upon this theory that, if these ill effects are attributable to feeding on the young shoots of a variety of Spinach, there is but a small number affected of those who eat it. The Chinese doctors think that it arises from irritation produced by a poison secreted by small greenish-yellow mites often found on Spinach. M. MATIGNON agrees with this opinion, which seems confirmed by the fact that ill effects are not felt when the Spinach shoots are carefully washed, or only eaten when cooked. Other hypotheses are admissible. It is possible, for instance, that these local troubles are produced directly by the mites. M. LAVERAN was impressed to see, in reading M. MATIGNON'S work, that only exposed surfaces are affected, that the right hand is more often injured than the left, and that the eruption is sometimes confined to the thumb and index finger of the right hand; that is to say, to the parts most exposed when gathering Spinach. It is comprehensible that fingers soiled with an irritant substance would easily infect the face, or that the mites would be sprinkled on the face, as on the hands and forearms. No gastric symptom is observable, the appetite is maintained throughout the course of the illness; this does not favour the idea of poison from any ingested matter. The mite mentioned as frequent upon Spinach shoots is perhaps one of those common in tropical America, which live in vegetation, and give rise, in human beings, whom they voluntarily attack, to intolerable itching, such as in our country is caused by the harvest-mite, a larval form of a mite of the Trombidium genus. The question should be studied from an etiological point of view, and the result of these complementary researches collated before the evil can be named; the title atropinism should apparently be discarded, as it is not the *Atriplex* which causes the mischief. *Revue Scientifique*.

DANEMARK.

ORCHID EXHIBITION AT COPENHAGEN.—A committee of Danish ladies arranged this month at Copenhagen a very interesting flower-show, partly consisting of Orchids brought home from London by the nurseryman and Orchid grower, Mr. O. Trier, at Copenhagen. Other Danish exhibitors sent a great many different species of Orchids in flower. Illustrations were furnished of Danish Orchid literature; also splendid paintings of the thirty-three species of Orchids indigenous to the country, and some of exotic species. The plants were nicely arranged in fine Danish ceramic ware, and the ladies had shown much taste and labour, having presented it all in a really delightful manner. The exhibition was visited by the entire Royal family, and had many admirers. The aim of this undertaking was to obtain funds for the Woman's Building at Copenhagen. At Chicago the Danish ladies exhibited very beautiful and useful objects.

The success attending this exhibition encouraged them to hold a grand exhibition during the whole of the summer of 1895 of objects entirely made by

women, which was also a successful undertaking, bringing in considerable financial gains.

The third successful and novel venture was the aforesaid Orchid Show, which affords a splendid example to ladies in other countries. II.

A GIGANTIC CYCLAMEN.

VERY much has been said and written of late about Cyclamens, and various modifications of existing types have been observed, that are likely hereafter to result in much greater variety in regard to the shape and form of the flowers. At the same time, there has been continued advance made in perfecting the well-known type, by obtaining increased size of flower with more substance, greater variety of colour, and better habit. In fig. 65 is presented a bloom taken from one of a few plants exhibited at the Drill Hall on the 9th inst., by the St. George's Nursery Company, Hanwell, when the strain obtained an Award of Merit. The segments of the flower were a trifle under 3 inches in length, of good substance, and the stems unusually stout. They were the finest Cyclamens we have seen.

THE INFLUENCE OF THE GRAFT ON THE FRUIT.

At whatever age in the history of horticulture the utility of the graft may first have been recognised, there is no doubt that a vast amount of information on the subject has gradually accumulated during an indefinitely long period of observation, and subsequently of methodical investigation. Extensive and important as the actual knowledge of the theory and art of grafting may be, there is also no doubt that much remains to be learnt, more particularly, perhaps, from a scientific standpoint. For although the most recent and authoritative works on horticulture indicate, for instance, nearly fifty different methods of grafting, the list is not infrequently extended by other new methods. Similarly, but to a much greater extent, is the knowledge increasing as regards the theory of grafting, the reason of course being that horticulturists were able to observe the apparent effects of the graft long before the physiology of plants was understood, even if considered. And even at the present day, not every man who can "graft" is in a position to investigate the effect of his work from a scientific point of view. To give the names of the men who have worked in this direction would be to mention many of the most eminent botanists of the century which is now at its close, and even a *résumé* of their interesting and useful results would extend much beyond the limits of a short article.

It is therefore now intended to refer to one aspect of the case only, viz., as regards the influence of the graft on the fruit of the Pear-tree, and in connection with a communication which has recently been made to the French Académie des Sciences, indicating the results obtained from observations made during three years by M. Gustave Rivière, the Director of the Versailles School of Horticulture, and M. G. Bailhache.

On the general subject of grafting, it may be mentioned in parenthesis, and in the words of M. Charles Baltet, one at least of whose classical works on horticulture has been translated into the English language, that whilst nullifying their existence the scion and the stock individually retain their original qualities, their characteristic properties, and each their proper constitution; their woody and cortical tissues continuing their development without any intermingling of their respective vessels or fibres. M. Baltet also employs a very graphic phrase, borrowed from the political world, which is, moreover, very applicable in this connection when he states that "grafting is a form of federative union wherein the interested parties retain their autonomy."

But whilst it is generally supposed and usually taught that the graft does not modify the specific character of the scion or of the stock, the above-mentioned explanation is not to be regarded as an absolute law, as has been shown by M. Daniel, whose researches on this subject have already been noticed

in this journal (*Gardeners' Chronicle*, 1895, part i., p. 140). Daniel was enabled to show that an alteration of taste in the scion and in the stock was obtainable by means of the graft, the most marked instance being that of the Savoy Cabbage grafted on the Turnip, whereby the former acquired to a considerable extent the very characteristic taste of the latter plant. The phenomenon was, moreover, proved to be more than temporary and fortuitous, inasmuch as the seeds obtained from the scions so grafted reproduced plants bearing the same "abnormal" characteristics of taste, and thereby indicating a real commencement of hybridity.

This change of taste resulting from the graft, as demonstrated by Daniel, nevertheless referred to herbaceous plants only, and the phenomenon would be all the more important if it also obtained as regards fruit-trees and Vines. Happily, said Professor Gourraud less than two years ago in the *Revue de Viticulture*, experience has hitherto shown that nothing similar occurs; and although, when the Phylloxera necessitated the reconstitution of many

that it has been observed for a considerable period that fruit trees in general, and some varieties of Pear-trees in particular, undergo certain characteristic changes according to the nature of the stock on which the grafts are placed. And if the essential peculiarities of the varieties are not altered, certain notable modifications obtain as regards the vigour and early maturity of the trees, and the weight, colour, and taste of the fruit when the scion is grafted on Pear-stock, and when it is grafted on the Quince. No precise scientific investigations would, moreover, appear to have been previously made on this particular subject, and Rivière and Bailhache conducted their researches during three years on absolutely identical conditions in connection with a variety of Pear known as the *Triomphe de Jodoigne*. The two trees selected for experiment were of the same age, viz. fifteen years old, their growth had always been normal, they were trained on the same system, they grew side by side, and their roots were consequently nourished by the same soil. But one tree was grafted on the Pear stock, and the other on the

(a) Average weight; (b) density; (c) proportion of free acid (expressed in terms of sulphuric acid); and (d) the total amount of sugar contained in the juice, a factor which, although the last-mentioned is not the least important. The difference, in fact, amounts to nearly nine grammes per litre of juice in favour of the fruit grown on the Quince stock. If the crop gathered from each tree be taken to consist of 500 Pears, each weighing 280 and 406 grammes respectively, the total amount of contained sugar would be represented by 7 kilos. (say 15 lb.) as regards the fruit grown on the Pear stock, and by 11 kilos. (say 24 lb.) as regards the tree grafted on the Quince.

MM. Rivière and Bailhache, moreover, record that certain analogous experiments conducted by them in 1886 and 1887 in relation to the *Doyenné d'Hiver* had given similar results as follows:—

Stock.	Average Weight of Fruit.		Percentage of Sugar in Juice.	
	Grammes.		Grammes.	
Quince	465		11.50	
Pear	230		9.04	

The final conclusions drawn from these observations is, therefore, stated to be that the stock exercises a notable influence on the scion, inasmuch as it apparently has the property of increasing or diminishing most of the physiological phenomena which take place through the agency of the scion, in the formation of the fruit. *Scion*.

HOME CORRESPONDENCE.

GESNERA ZEBRINA.—This species and *G. cinnabarina*, known also under the name of *Nageelia*, are among the most useful and showy of the easily-grown, old-fashioned stove plants. Leaves and flowers are almost equally showy. Mr. Edward Bennett writes with the ease and authority of a master (p. 193) on the culture of these fine *Gesneras*, and yet he gets on very doubtful ground when counselling that the plants should be stopped when 4 inches high. On the contrary, any stopping of these semi-tuberous-rooted *Gesneras* is a mistake. It is a waste of time, as well as a sacrifice of beauty; and as the roots multiply fast enough, there is no excuse for stopping them to induce denser masses of fine foliage or of bloom. The natural stature or habit of these *Gesneras* is as perfect and pleasing as can be imagined, spikes and foliage being admirably balanced and blended. For general furnishing purposes these *Gesneras* are most useful when grown in 6-inch pots, and larger masses may readily be had, true to character, by planting from three to a dozen or a score of roots in a pan, vasa, or wire basket. *J. T. Fish.*

CHICNOSCILLA ALLENI.—Kindly note that the name I gave to the natural hybrid between *Scilla bifolia* and *Chionodoxa Lucifera* was *Chionoxa*, and not *Chionoscilla*, as spelt by Mr. Nicholson on p. 191 of your last week's issue. These plants vary very much in the size, colour, and general character of the flowers, but so far I have no white variety to record. Some of them are very beautiful, and one form I have is larger than any *Chionodoxa* I have seen. *James Allen*. [The spelling adopted by our correspondent is not consistent with the grammatical requirements of the case.—Ed.]

EUPHORBIA JAQUINÆ-FLORA.—I was glad to read Mr. Baxter's note in favour of this brilliant winter-flowering plant. We have few, I had almost written no plants to equal it for decorative purpose in the dead season. The *Euphorbia* (*Polioetia*) may almost match it in brilliance, but it is heavy and coarse in contrast with the grace and lightness of this queen of the genus. I have little to add to the cultural notes of Mr. Baxter, supplemented as it is by the editor's suggestion of growing on right or ten cuttings without potting them off singly. This secures a bush of brilliant flowers, without the temptation to stop the plants; and if the cultivator does stop the *Euphorbia jaquinæiflora*, he gains nothing by it: he simply sacrifices vital force, and loses time. The shoots stopped after a time seldom break out more than one shoot. I have never succeeded, nor have I ever seen, this brilliant *Euphorbia* stopped, pruned, or trained, into living masses of

FIG. 65.—A GIANT CYCLAMEN OF A STRAIN SHOWN BY THE ST. GEORGE'S NURSERY CO., HANWELL. (See p. 206.)

French vineyards by the American *Vitis riparia*, it was stated by many growers that the native Vines were losing their qualities and becoming "riparianised." For experiments conducted on an extensive scale afterwards indicated the supposition to be ill-founded, and that as excellent Grapes for the table are obtainable on the native as on the American stock. Similarly with fruit trees, says M. Gourraud, Pears true to taste being obtained from grafts on the wild stock, with its bitter fruit; and the Sweet Almond may be grafted on the Bitter Almond without any modification of flavour. The same observer also stated that the only apparent effect of the graft, at any rate as regards the Vine, consists in a difference of vigour which is generally less marked, and of fructification, which is generally more abundant, consequent on the natural results of a greater or less affinity between the scion and the stock.

This opinion would not, however, appear to be applicable, without modification, to the fruit of the grafted Pear-tree, in consequence of the recently reported experiments of MM. Rivière and Bailhache, to which reference has already been made, and of which a full account is to be found in the *Comptes Rendus* (tome cxxiv, p. 177). These gentlemen state

Quince, and the following table shows certain variations in the nature of the fruit as indicated by analysis made in 1894, 1895, and 1896:—

Nature of Fruit.	On Pear Stock: Green.	On Quince Stock: Golden Yellow, Rose-tinted towards the sun.
	Grammes.	Grammes.
Average weight (of 10 Pears) ...	280	406
Density of fruit	0.993	0.9987
„ of juice (at 15° C)	1.046	1.051
Acidity of juice (per litre)	1.070	1.126
Grape sugar, per litres of juice ...	90.036	95.456
Total sugar, „ „	9,400	102,333
Ash, „ „	2.165	2.463

These figures, as above indicated, are rather intended for comparative purposes; and for this reason, as well as for the sake of simplicity, it has not been considered necessary to convert them into English equivalents. It will be observed that these results show, as regards the fruit obtained from the *Triomphe de Jodoigne*, grafted on Quince stock, a superiority in respect of, *inter alia*—

brilliance. The nearest approach to this has been reached by clothing walls, rafters, roofs, with vigorous young plants from 6 to 9 inches or less apart, and letting them run, grow, and bloom unchecked and un hindered. The well-ripened wood of the previous year will also at times break freely, when it has grown near to the glass in a blaze of light. *D. T. F.*

VICTORIAN ERA FUND.—No one appears to take up the suggestion put forward by Mr. Harris, of asking young gardeners to subscribe this year to the above Fund. As one of the young men, I should be very pleased to contribute; and I am sure if head-gardeners would bring the matter before the young men serving under them, the response would be a very liberal one. I should like to remind your correspondent "Life Member and Annual Subscriber," that the young men are not any the less gardeners, and it is to us the committee will look for new members and annual subscriptions a few years hence. I hope the sum mentioned by Mr. Harris may be reached, and feel sure the young gardeners only need to be asked, and they would subscribe freely; for what project could be more worthy and deserving of support than a fund to help our brother gardeners in distress? *J. C. P.*

THE EUCHARIS MITE.—Some few years since I experienced considerable trouble with the mite. The affected plants were possessed of a few leaves only, and these had a sickly appearance. New and apparently healthy stock was procured, which in a short time assumed the unhealthy appearance of the infested plants. Various means were adopted to eradicate the pest, such as cutting away the diseased portion of the bulbs and washing them in strong solutions, and afterwards potting them in fresh compost. The plants recovered a little strength after such kind of treatment, but in the course of a few weeks they returned to their previous condition. Ultimately, after several ineffectual trials to restore them, it was decided to place them in a lower temperature. With this object in view, they were moved to the north side of a three-quarter-span house in which Ferns, chiefly Adiantum, were grown, and in which an intermediate temperature was maintained. No attempt whatever was made at this time to eradicate the mite, as it was considered hopeless without destroying the plants. The plants were removed early in June, and in a few weeks afterwards there was a marked improvement. Six months afterwards, some of those growing in 8-inch pots, measured nearly 4 feet in diameter. Two conclusions were drawn from this unlooked-for and most welcome change, namely, that the plants had been subjected to too much heat, and that the cause of the unhealthy condition was the cause of the result, and not the cause of the decay of the bulbs and their roots. There were several reasons for coming to these conclusions, one of which was that when they were grown along with other plants requiring a stove temperature, they were invariably in their worst condition in the summer. Upon the approach of winter, with its dull dark days and a lower temperature, they showed a slight improvement. While in their new quarters it was observed that they could not bear so much light and sunshine as the Adiantum without injury. During the winter an abundant supply of fresh air was admitted both day and night with evident advantage to the plants. In a few months the mite had completely disappeared, during which time no insecticide or mite-killer had been applied to them. All that they received besides water was an occasional application of liquid-manure. I am fully convinced that in this instance the unhealthiness was brought about by employing too high a temperature, and affording the plants too much sunshine. *H. Neild, Cheshire Agricultural and Horticultural School.*

A RAID OF VOLES ON THE SCOTS FIRS.—Just after the last brief spell of frost and snow was disappearing at the end of last month, on examining a large block of two year transplanted Scots Fir growing in our nurseries, we were surprised to find that the points of the plants were completely eaten away. Knowing that this damage could not have been caused by squirrels, as none of these bushy-tailed denizens of the forest haunt this neighbourhood, we were somewhat puzzled to know the right cause. The suspicion that any kind of game could have done the damage was very remote, as the land on which the Firs are growing is far from any game resort, and is close to a public and much-frequented highway. In our dilemma we sought counsel from Mr. Malcolm

Dunn. With his usual courtesy and promptitude, Mr. Dunn replied to our enquiries as follows:—

"DALETH GARDENS, February 27, 1897.
"DEAR SIRS,—I have examined the specimens carefully, and I believe it is the work of field mice or 'voles,' as it is exactly like what I have seen done by them on one or two occasions. On one of these I watched and saw scores of voles nibbling the buds out of the points of young Scots Fir, three years planted out, and about 4 feet high. They quite ruined an acre or two of the plantation, which had been formed on rough grass land. About a quarter of a mile from the plantation there was a small home nursery enclosed with hedges, and a hedge ran from one corner of it direct to the Scots Fir plantation (it was a 'mixed' plantation, but Scots Fir were three to one of all the others, and the Scots Fir, as well as some other trees, were attacked, and their buds badly eaten out one winter by the voles. It was at first thought to be the work of squirrels, but none was ever seen in the nursery, and there was no wood with large trees near to harbour them. On examining the hedge that ran across the grass field to the infested plantation, it was found to be full of vole 'runs' amongst the coarse herbage at the bottom. We cleared out the hedge bottom, destroying the cover for the mice, and in their runs, and the voles troubled the nursery stock no more. This happened in Worcestershire in the early 'sixties.' I have only once seen a similar attack, about fourteen years ago in Nottinghamshire, but the forester in charge of the plantation had no doubt about the cause of the injury, as he had seen the 'mice,' as he called them, sitting on the trees nibbling the buds. If black game (muirfowl) were plentiful near Kelso, suspicion might rest on them, or on capercaillie, but neither, I believe, seen in your neighbourhood. Moreover, I am quite sure it is not their work, which is much more roughly done—their leaves are seen to be bitten being pecked off by them. Have you any rough grass or similar cover near the Scots Fir in which the voles can harbour? Dirty bottoms of hedges are good shelter, also rough grass and weeds."
"MALCOLM DUNN."

On receiving Mr. Dunn's diagnosis, we proceeded to act upon it by setting mouse-traps among the Scots Firs, and on the very first morning thereafter we secured a big 'bug' of voles, which, without doubt, had been the deprecator. An old hedge banked up in front with loose stones, and here and there an old Ash tree with immense spreading roots, had provided a good harbour for the voles. In all our experience, however, we never had any Scots Fir—or, in fact, any other young trees attacked by voles, and it would be interesting to know whether any other nurserymen have suffered any damage this winter from these destructive vermin. Of course, the damaged Scots Firs were burned at once; and, as the traps have been kept set ever since, the plague has been stayed, though not before a large number of voles had been captured. To all appearance, however, the pest has now been effectually stamped out. *Lainy & Mather.*

THE LATE DR. HOGG.—To some of us it only seems a few years since he, in connection with Mr. Johnson, was launching the *Journal of Horticulture* and its new name, and enlisting Donald Beaton, Robert Fish, Mr. Errington, and other eminent horticulturists on the staff of the journal. And now, scarcely any of the veterans are left, and the founder and zealous proponent of the journal has fallen. I look upon the *Fruit Manual* as the greatest of Dr. Hogg's publications. After the death of Mr. Robert Thomson of Chiswick, Dr. Hogg filled the highest place of honour and usefulness in British pomology; and his life-work was chiefly devoted to the raising of British fruit-growing to high rank among our national industries. Had Dr. Hogg gone abroad and annexed thousands of acres of someone else's land, or killed a few thousand savages, he would doubtless have been honoured by the bestowal of a title. But as he devoted his life to teaching how more and better fruit might be grown for the masses, and making life more worth living for all, he passed away without state honours or state favours. But his work will endure, and there are few cultivators among us who are not grateful for the services Dr. Hogg rendered to them throughout his laborious and honourable life. Beaton and Johnson to his memory. We are not likely to look on his like again. *H. T. Fish.*

—The death of Dr. Hogg is another reminder of the dropping of links of the chain of distinguished horticulturists since I went to Meadow-

bank in 1854. I was drawn first as a writer to the *Cottage Gardener* and the *Journal of Horticulture*, a few years after that time. I recollect in my first visit to London after leaving Hugh Low's nursery—where, by the way, there was not a single Orchid potted, although the son in Dorset sent home lots of plants which were disposed of at Stevens' Rooms—of dining with the Doctor and his coadjutor, Johnson, who was very dear, at one of the best hotels, along with the late William Thomson, when we had a most happy evening. Dr. Hogg and myself, always intimate, but rarely a little from each other by our different studies, met occasionally, especially after the marriage of his daughter to a Glasgow gentleman. Alas! what of our compeers? The gaps that are occurring year by year make me begin to think I am getting old, although physically I am as well as ever. How changed Orchid culture now is! Many will remember my beating soundly all comers for two years in succession from Scotland—little Scotland. Now you could not, if you were trying to live by selling Orchids in that country, make as much as would buy seed to feed a canary. This town is now the great centre of Orchid wealth. In a circle of 30 miles from Manchester there is more money spent in Orchid-buying than in all England and Scotland lumped together. Yorkshire does not count for much, large as the county is, and if trade were bettering, the growers of Orchids would double in number in a short time. After reading your touching notice of our old friend, I could not resist penning you these few words. *J. Anderson, Manchester.*

ENGLISH ORCHARDS.

(Continued from p. 185.)

BETTER selections of Plums are much needed, and owners of orchards will be wise in making an endeavour to extend the season as far as it is possible to do so by growing more early and late varieties. A good selection for orchards would comprise Rivers' Early Prolific, The Ozar, Green Gage, Paul's Seedling, Victoria, and Monarch. I do not propose discussing the details of grafting, but would strongly advise, that instead of the trees being headed back to the trunk or to the base of branches with a diameter of 4 or 7 inches, in accordance with the practice that largely obtains, they should be simply cut back to the smaller branches not exceeding 2 or 3 inches in diameter, and a graft placed on each shoot. Not only will the trees be more perfect when the smaller branches are grafted, but there will be a considerable saving in time, as fruitful heads will be obtained in two or three years.

In the renovation of orchards that have become unproductive through bad usage, attention should first be directed to the restoration of the vigour of the trees. The heads should be thinned by the removal of useless spurs, and the cutting-back of weakly branches; and when this has been done, spray the trees with warm water, in which has been dissolved custic soda and commercial potash at the rate of 1 lb. each to 25 gallons of water. This mixture, applied in the form of a spray during the winter or early in the spring, will clear them from moss and lichen, and I destroy the eggs and larvae of some of the insect pests. If the trees are infested with American blight, as, unhappily, many of them are, means must be adopted for the eradication of the pest, and there is not a better method than that of dipping the infested parts with a mixture prepared by dissolving 1 lb. of carbolic soft-soap in a gallon of hot water, and then adding 1 pint of petroleum, and well incorporating it while hot. As the starved condition of the trees is necessarily due to the impoverished state of the soil, it follows as a matter of course that the soil be enriched, and that the manure be used where available, and increased for the purpose of stimulating them into activity. There is no better course of procedure than to break up the surface of the soil to a depth of 3 or 4 inches in the autumn, and dress with lime; and early in the spring apply a heavy dressing of manure or artificial manure. Farmyard or stable manure should be used where available, and if this is not at command, use artificial. An excellent mixture of these would be one consisting of three parts by weight of muriate of potash to five parts of superphosphate of lime, and 8 cwt. per acre will be a good rate at which to use it. A liberal dressing of soil will also be beneficial, as would a dressing of nitrate of soda at the rate of 1 cwt. per acre, after the trees have commenced to make new growth. The breaking-up of the surface soil, as here advised, will have a highly beneficial effect upon the trees; and I would mention that while excellent crops may be obtained from orchards, it is only by the use of the spaces between the trees that the finest fruit can be obtained.

I might speak at length on grading, packing, and marketing, for the owners of orchards have much to learn before they can achieve success in carrying out these important details, but am anxious to avoid unduly taxing your time. The question of storage is also of pressing importance, and I would strongly advise that in connection with all orchards of any considerable extent there should be a spacious store-room. This need not be elaborate in detail, or costly in construction, but it should be substantial, and so designed that a low and uniform temperature can be maintained throughout the winter. An orchard, in fact, to be best produced and most profitable, a spray

roof structure about 12 feet in width and 10 feet or so in height, and fitted with open shelves on either side, will perhaps be the best form of structure, and if it be provided with double walls, double windows, and double doors, and a thick roof of thatch, the fruit will have the advantage of being raised in a suitable temperature. It is not without considerable regret that I have to dismiss the question of storage thus briefly, for it has an important bearing upon the profitability of our orchards. In conclusion, then, the owners of orchards have, generally speaking, not only to learn how to restore their orchards to fruitfulness and multiply them to that condition, but they must learn also to store the produce until such times as they can place it upon the market with most profit to themselves. The owners of English orchards have certainly much to learn and much to accomplish before the 212,000 acres devoted to fruit can be brought into so favourable a condition as to enable them to compete successfully in their own market with foreign and colonial produce, as they should assuredly be able to do, for in no other part of the world do growers of similar kinds of fruit to those discussed, viz., Apples, Pears, and Plums, enjoy greater natural advantages.

NEW INVENTION.

THE VAN REYPER GLAZIERS' POINTS.

In fig. 66 is illustrated a patented glazier's point that has been in use in America for a considerable time past. The Van Reyper's perfect glaziers' points are said to never work out after being properly driven in, which is an easy operation with a square-headed hammer. It is a convenience also that there are no rights and lefts, and they may, therefore, be used on either side of the sash-bar. If the glass should get broken, the points can be forced out in perfect condition by the use of a chisel. For preventing the glass from sliding, they are recommended as the best means possible. Messrs. Barr & Sons, Covent Garden, W.C., are the agents for the sale of the articles in this country.

SOCIETIES.

HORTICULTURAL CLUB.

VARIATIONS OF SEEDLING FRUITS.

The following remarks were made by Mr. T. FRANCIS RYVES on the occasion of the meeting of the Horticultural Club, held at the Hotel Windsor, Victoria Street, S.W., on March 9, as notified in our last issue:—

"No doubt raising seedling fruits has for many years been a matter of great interest to those who have entered all forms of fruit-culture, and pomologists have attempted, with more or less success, to produce varieties of fruit with rather less than more success. One name, that of Andrew Knight, has achieved a lasting reputation in England, and the name of Van Mons in Belgium is equally well known as the raiser of numerous Pears, the greater part of which have not retained all the position he claimed for them. The Pear known by his name, the 'Van Mons' (Leon le Clerc), was not his seedling, but was named by the raiser (Leon le Clerc) as a compliment, the compliment being returned by a Pear named Leon le Clerc (Van Mons), which is a very inferior fruit, and fit only for the kitchen.

The number of Pears described by André Leroy and Dr. Hogg testify to the persistent attempts of seedling fruit-raisers to obtain Pears of superior quality. It is natural to suppose that for this purpose the fruit selected for sowing would be of the best quality, and yet how disappointing are the results. Now fruits appear and disappear in regular order, but whether they are raised by seedling or chance is seldom indeed that varieties carefully cherished by the raiser fulfil the description given of their qualities.

The eccentric differences observable in Pears alone, are exasperating. Crossing with sorts possessing superior qualities does not appear to give any special results; there is always the element of chance, and the careful experimenter is beaten by a chance-grown seedling. The Duchesse d'Angoulême, a most popular Pear in France, the climate being better suited for its development than in England, was found in a farm-garden near Amiens; Henri de Rance also being derived from a small village garden in Picardy. There is a strange adherence to the prototype in some Pears the Jargonelle for instance. This Pear is a standard of excellence of some. Under the name of Epargne it is said by André Leroy to have been a popular Pear in France in the year 1580. During this long period there does not appear to have been an exact reproduction by seed. Spontaneous there are in plenty. L'Arve gives twenty-two; but there is not a single hint of any of these synonyms being seedlings.

One of the oldest known Pears in England, the Autumn Bergamot, as it had been introduced by the Romans, has seedlings in plenty, and a long list of synonyms, but apparently not exact reproduction. The seedlings are called the later, larger and smaller, but none are exactly like the prototype. Another popular Pear, the Marie Louise, persists

in keeping the place it has gained; numerous synonyms, but no seedlings, which exactly reproduce the original. This Pear, from its excellent quality, must have been a source of many experiments. Of other types of Pears which have not been reproduced, the following will be familiar examples:—Williams' Bon Chrétien, Louise Bonne de Jersey, Glot Moreau, Boyenid au Comice, Passe Colmar, and Easter Beurré, though they have been in existence long enough to have produced many seedlings. I have raised seedlings from these varieties, and have not gained a single fruit like the parent, and, in fact, all have been more or less worthless.

As with Pears so with Apples. The Ribston Pippin has not, to my knowledge, been reproduced; it is said to have been raised from a chance seedling. The Wyken Pippin, a very old and esteemed variety, has not been reproduced, or the King of the Pippins, and Golden Pippin. Old Nonpareil, of which the seedlings are nearer the prototype than most of the old varieties, is not exactly reproduced.

The Peach is perhaps the fruit which approaches more nearly reproduction than most, but it does not differ much from the apparent rule of diversity. The Grosse Magnoime, Bellegrape, and Madeline have numerous seedlings which approach the originals in quality, but differ in the flowers and glands. The catalogue of the Royal Horticultural Society enumerates forty synonyms of the Grosse Magnoime. These do not appear to be seedlings, but the names seem to have been given by those who have grown the sorts, but lost the original names.

Nectarines are subject to the same law. The Erloge and Violotte Hâtive seem to have kept their types. The Plum has also an apparent fixity of tenure. The Green Gage, which was introduced into Europe many centuries since, seems to have adhered to its prototype, although it is said to be raised from seed, with the result of perfect reproduction. The number of synonyms points rather to the fact that seedlings vary, as do the seedlings of other classes. The Early

FIG. 66.—THE VAN REYPER GLAZIERS' POINTS.

A, sash-bar.
B, E, sheets of glass.
C, C, the points at which the glazing points are inserted.
D, G, and H, the cabinet.

Profile, of which I have raised many seedlings, does not reproduce itself, and the fruits differ essentially from the parent.

It is the same in the case of Cherries. The numbers of synonyms recorded to the May Duke, Bigarreau, and Reine Hortense, seem to show that exact reproduction has failed. The subject is interesting, and is capable of much extension. In our uncertain climate the aid of glass is almost absolutely necessary, and the experiments, if a man wishes to see the results, should be begun at an early age."

ROYAL HORTICULTURAL.

MARCH 23.—There was another large display on Tuesday last, when the usual fortnightly meeting of the committee was held in the Drill Hall, James Street, Westminster. The hall was not crowded, however, to the same degree as at the previous meeting, when the number of exhibits was quite exceptional.

The Orchids now form a very important feature, as there are many species in bloom, and on Tuesday some excellent examples of cultivation were shown, particularly a plant of *Platanus Cooksonii* from N. C. GOSWOLD, Esq., which yielded many flowers before seen. Spring flowers, such as Hyacinths, Tulips, Narcissus, Cyclamens, border and Alpine plants, occupied much of the space, and good collections of each were shown. *Hippocrepis* too were staged in several instances, including a large group from Liverpool. The rest of the exhibits included miscellaneous plants staged for certificates; also Rose blooms, Camellias, and groups of ornamental plants. There was but little fruit contributed, and in the competition for fruit in Pears, the display made was exceedingly weak. The attendance throughout the day was good.

Floral Committee.

Present.—W. Marshall, Esq., in the chair; and Messrs. H. B. MAY, R. DEAN, H. HEROLD, Geo. SIMONS, J. JENNINGS, J. H. HOBSON, Chas. JEFFRIES, Geo. NEHOLSON, J. FROXY, J. D. PAULY, W. BINN, THOM. PEEL, Geo. E. PEARSON, C. F. SHAW, H. J. JONES, Ed. Mawley, H. J. CUTBUSH, Ed. BELLETT, D. B. CRANE, T. W. SIMPSON, C. BLOK, H. TORNER, Geo. PAUL, OWEN THOMAS, and Jas. Walker.

An extremely pretty collection of filament-peduncled Begonias was staged by Messrs. H. CARSTEL & SONS, Stranely. Several varieties of the manilla type were exhibited, and one of the best of other varieties shown was *Pand. Brant*, rosy-pink, an unusually floriferous variety. There was considerable amount of fruit among the Begonias, and all of them are desirable (Silver Bankian Medal).

Roses were again magnificently shown by Mr. GEO. MOYR of Canterbury. A good number of Tea varieties were included in this collection, and a dozen and a half blooms of *Sol. Flora Medal*.

From Mr. H. W. LOCKING, Gables, Wantage, came a dozen fine blooms of *Camellia rubra*, and a group of flowers and a spray of blooms of the Rose *Fortuna's Yellow*, a capital old variety of exquisite colour and fragrance (*Bronze Bankian Medal*).

Mr. WILLIAMS, 57 to the Duke of Marlborough, Bloemhof, exhibited blooms of *Camellia La Valletta*, and a plant in flower of *Camellia Mrs. Wynn*. The former is a large rose-coloured flower with white edges, the latter a bronzy-yellow colour.

MESSRS. LAMBEY, Brussels, were recommended an Award of Merit for a variety of *Anthurium Scherzerianum*, named 'Good Slaughter.' It has an extra wide spathe, long almost round.

A fine clump of *Disporum Leschenaultianum*, shown by Messrs. JAS. VEIL & SONS, represented a plant that will be very useful for decorative work. In appearance it is like a variegated *Solanum's* Real, but is branched, and has more leaves. It is perfectly hardy, and possibly of use for forcing (Award of Merit). Two plants of *Rhododendron* in flower (Award of Merit) from the same establishment; they were shown from seeds brought from China (Yunnan), and are said to represent new species. In both cases the flowers were small, and the inflorescence short. Messrs. VERRILL also exhibited some very fine *Hippocrepis* sorts, and an Award of Merit was recommended to Fern, a large flower of fairly good form, excellent substance, and in colour velvety-scarlet marked with white.

There were a few other varieties of *Hippocrepis* contributed by Captain HOLLORS, Westonsart, Tetbury, Gloucester, in which the colours were dark and good. *Hippocrepis* are seldom contributed to the Drill Hall from the Liverpool district, but upon this occasion there was a large group of these plants in flower from Messrs. R. P. KIR & SONS, Albright Nursery, Liverpool. It contained some very meritorious varieties, among which we may instance *Yantha*, a self-coloured scarlet; *Ajax*, crimson; *Scarlet Gem*, Lotheria, Imperial, Melpomene, a light-coloured flower; *Titanic*, etc. (Silver gilt Flora Medal).

Hyacinths and Tulips in pots from Messrs. W. ORCHARD & SONS, Highgate, London, N., made a grand display. These are noticed on p. 209. Messrs. VERRILL had also a few *Crocus* in flower, and *Magnolia Alexandrina* in bud, *Calla Elliana*, *Wickstraria sinensis*, *Pearus*, *Cerasus avium*, *B. pl.*, *Lilium*, etc. (Silver gilt Flora Medal).

An excellent *Crocus*, named *Cs.* *Vernida*, shown by Messrs. W. BALGUS & SONS, Richmond, was deservedly recommended an Award of Merit. It produces a large, compact tuft of fine flowers.

Messrs. JAS. LANGE & SONS, Forest Hill, S.E., exhibited a large number of *Hyacinths*, named *Sanguinea*; and a plant in flower of *Richardia Pentlandii* *maculata*, with spotted foliage.

From Messrs. R. & G. OPPER, Southgate, was exhibited a collection of a named Tulips suited for forcing, which was awarded a Bronze Medal.

An unassuming but interesting display of *Narcissus* and Tulips in pots was made by H. TATE, Esq., Park Hill, Stratham Common. The collection rather crowdedly filled the table that runs across the hall near the entrance door, and contained numerous varieties of each genus (Silver Bankian Medal).

Groups of miscellaneous plants were well shown by Messrs. JAS. LANGE & SONS, Forest Hill, London, S.E. (Silver Flora Medal); and Messrs. J. DELO & SONS, Rompall Park Nurseries, Newwood Road, London, S.E. (Silver Bankian Medal).

Tulipa Kaufmanniana shown by Messrs. WILKIN & CO., Tottenham, and Messrs. BARR & SONS, Tottenham, was awarded a First-class Certificate. It is a new species of Tulip to come from Turkestan. The segments are large and broad, yellow from the base to about half way up, and white over the remainder; some of the segments were reddish on the exterior, but this colour did not appear in all of the flowers. It is a showy species.

Erythronium Nutt. dianum, exhibited by the two firms just mentioned, was recommended an Award of Merit. The flowers are yellow, two being produced usually upon a spike; a distinct and pretty species.

A Botanical Certificate was awarded to *Fritillaria alpinia*, exhibited by Messrs. BARR & SONS. It is one and upon flowered; the blooms are purple outside, and yellow on the interior. Messrs. WILKIN & CO. exhibited several other *Erythroniums*, including *Hubert's* and *Hartweg's*.

Messrs. W. GARDNER & SONS, Colindale Nurseries, Murray Park, Finchley, exhibited a choice lot of varieties of *Primula* in a basket, also some *Scilla's* in a bowl. A choice variety of *Primula caschmirana*, and an open *Artemisa* with variegated foliage, were included (Gold of Thanks).

Messrs. PAUL & SONS, Old Nurseries, Chessington, had a pretty group of hardy and alpine plants. We observed the specimens of *Paeonia*, *Artemisa*, *Anemone pulchella*, *P. p.* *pubes.* *Androsace cuneata*, also a species of *Dianthus* and *Saxifraga* in flower. A plant of *Heulias Anemone* was

dishes being staged. The 1st prize was withheld, and a 2nd prize awarded to Marie Guise, shown by Mr. W. H. Divers, gr. to the Duke of Rutland, at Belvoir. The fruit was from a pyramidal tree upon free stock in clay soil.

The best Apple was Allen's Everlasting, shown by Col. Huxley, M.P., Hington House, Dorsetshire. It was on a pyramid upon fruit culture generally, in which the keen competition of the present day was referred to, and an observation made that in the future the fruit grower must guide his hand by his head to an increased extent, and there must be less "rule-of-thumb" practice. The Rev. Gordon Salmon then proposed the Rev. Geo. Henslow to read a paper on the effect upon the stock and scion, its advantages, &c. Excellent hints were given upon budding in regard to the selection of healthy and matured stocks, and upon the selection only of first-class varieties for the supply of buds. The importance of attention upon the soil, of the proper ventilation and draining of the soil with a view to preventing "chills" upon the roots, was insisted upon, and the excellent practice of encouraging the formation by the trees of "fruit fibres," or more properly "root fibres," such as are known to be conducive to fruitfulness, was again recommended. It was, however, stated that, just as poverty of root fibres resulted from the soil, so might excess be brought about by an excess of such fibres, by the production of an over-supply of sap, which in the tickle and often adverse weather prevalent, was liable to burst the ducts and bark.

The remainder of the paper dealt with experiments the Rev. Geo. Henslow had made in budding and rebudding varieties of fruit trees with each other. The conclusions arrived at which Mr. Salmon regarded as proved beyond doubt, were—(1), that by frequent budding, new life, a better constitution, and greater productiveness can be imparted to old trees; and (2) that new and improved varieties may be obtained by the same means. Mr. Salmon also mentioned the various known sources on good and not so good stocks. The budding is done in June, and in the following April the bud commences to grow whilst in the autumn of the following year a little fruit is produced.

Lecture on the Effects of Budding.

In the afternoon a lecture was given by the Rev. Gordon Salmon, M.A. (Yorkshire), upon "Bud Transference and its Effects on Fruit." The first part of the lecture was an Essay upon fruit culture generally, in which the keen competition of the present day was referred to, and an observation made that in the future the fruit grower must guide his hand by his head to an increased extent, and there must be less "rule-of-thumb" practice. The Rev. Gordon Salmon then proposed the Rev. Geo. Henslow to read a paper on the effect upon the stock and scion, its advantages, &c. Excellent hints were given upon budding in regard to the selection of healthy and matured stocks, and upon the selection only of first-class varieties for the supply of buds. The importance of attention upon the soil, of the proper ventilation and draining of the soil with a view to preventing "chills" upon the roots, was insisted upon, and the excellent practice of encouraging the formation by the trees of "fruit fibres," or more properly "root fibres," such as are known to be conducive to fruitfulness, was again recommended. It was, however, stated that, just as poverty of root fibres resulted from the soil, so might excess be brought about by an excess of such fibres, by the production of an over-supply of sap, which in the tickle and often adverse weather prevalent, was liable to burst the ducts and bark.

The remainder of the paper dealt with experiments the Rev. Geo. Henslow had made in budding and rebudding varieties of fruit trees with each other. The conclusions arrived at which Mr. Salmon regarded as proved beyond doubt, were—(1), that by frequent budding, new life, a better constitution, and greater productiveness can be imparted to old trees; and (2) that new and improved varieties may be obtained by the same means. Mr. Salmon also mentioned the various known sources on good and not so good stocks. The budding is done in June, and in the following April the bud commences to grow whilst in the autumn of the following year a little fruit is produced.

Mr. J. S. Chel, after acknowledging the suggestive character of the paper, said not only that new varieties could be originated by grafting, and further said that experience had proved that the descending sap from scion influenced the stock in a greater degree than the ascending sap of the stock influenced the scion. Ribston Pippin Apple was first increased by grafting for scores of years, and it remained Ribston Pippin until Mr. A. Dean took a similar view, & expressed a hope that the Rev. Gordon Salmon would avow the Fruit Committee by sending some fruits next autumn for the Committee's inspection, and also details of the budding, that had taken place in each instance. The Rev. Geo. Henslow, in his remarking upon the general stability of grafting, and of plants propagated by means of the vegetative system, drew attention to Mr. Bailey's work, 'The Survival of the Uddle' (reviewed in *Gardener's Chronicle*, p. 69, Jan. 30, 1897), in which this question is detailed. There it is stated that Newtown Pippin Apple, when grafted in different States in America, produced different varieties, and it is known that new varieties are frequently brought about by the vegetative parts of a plant alone, as in spots.

As the Rev. Geo. Henslow and Mr. Ruppell remarked, however, it is probable that such changes in the character of Newtown Pippin Apple in America is due to a greater degree to "chilled" varieties than to the effects of grafting, though all agree that the stock does exert an influence upon the scion, and vice versa. See also article on p. 20.

DEVON AND EXETER GARDENERS' ASSOCIATION.

MARCH 17.—The fourth spring show, and, in point of quality, by far the best the Society has had, was held at the Royal Palace, Exeter, on the above date, and was well attended. The number of competitors was slightly fewer, but the number of entries greater, than on any former occasion.

A new competitor at this show, though well known as an exhibitor throughout the West of England, was Mr. W. ROWLAND, gr. to Mr. W. B. Brock, Parkerswell, who staged some fine specimens of *Azalea*, *Camellia*, *Delphinium*, &c. The competitors in this class for twelve flowering plants were far behind, and their exhibits consisted of the smaller plants, such as *Hyacinths*, *Tulips*, *Freesias*, &c., and the competition was very close. Mr. T. Baker, gr. to Mr. T. M. B. Robertson, *Camellia*; Mr. P. Rogers, gr. to Mr. J. R. FABIAN, St. Thomas; and Mr. C. D. GIBSON, gr. to Mr. RANALL JOHNSON, Port View, running each other fairly close throughout, and in the order of their names. The Challenge Cup given by Mrs. THORNTON WEST, Stratham

Hall, for the largest number of winning points, to be held for twelve months, was won by Mr. ROWLAND. The president, Mr. E. A. SANDERS, Stoke House (gr. Mr. J. WEEKS), sent an excellent collection of conservatory plants, which occupied the top table, and greatly contributed to the effect and colour and form of the flowers being very good.

Among the fruit exhibits was one from Messrs. ROBERT VERTCH & SONS, The Royal Nurseries, a first-class collection of *Hyacinths*, remarkably well grown, the trusses being well finished, and the foliage of a dark tint, and robust. Messrs. VERTCH showed a fine collection of *Narcissus*, including many of the new varieties. They also exhibited a number of plants of the new yellow *Violet*, "Sulphurica," some fine plants of *Rhododendron Veitchii*, and other meritorious plants. Mr. GEORGE KERSEWELL, St. Thomas, staged a nice bank of *Palmis* and flowering plants, including a magnificent white *Azalea*. JACOB, Limited, showed from the chairman, Col. CLYDE THORNTON'S conservatories at Teignmouth as fine and healthy a lot of greenhouse plants as one could wish to see. They were all growing in *Jadeo* fibre, and were pictures of health and beauty. Mr. W. J. GORNEY showed some of his new *Pelargoniums* and *Delphiniums*, and also a number of plants of his floral designs suggestive of public commutation decorations.

BIRMINGHAM GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.

The Hardy Bulb Culture in England.

[By F. V. BRENDEN, M.A. Read before the Birmingham Gardeners' Mutual Improvement Association, March 15, 1897.]

We are told by politicians now-a-days that thrift and home industries are essential, and while some advocate milk or meat, or poultry and eggs, or jam-making, or the "Busy Bae" industry, I will advocate bulb culture.

We have here in Birmingham our friends Mr. W. SYDENHAM and Mr. POPE, and others interested in bulbs, but I should like to see every small farmer, every cottager and allotment holder, and even the railway porters, growing at least a few bulbs for sale.

In Holland and elsewhere, it is the small growers who export the greatest numbers of bulbs, and they should like to see the day when Mr. Sydenham and others of our great bulb merchants are not obliged to go over to Holland with their big cheque books once or twice a year.

Bulb growing is safer and more pleasant than gold or diamond digging, even though, perhaps, not quite so profitable. It yields "beetle beams" and breweries, or some earned shares on 'Change.

We all want more faith. If the English gardener has one greater fault than another to-day, it is that he does not believe in himself, and in the soil and climate of his native land.

So far as general English and garden skill are concerned, no gardener on earth can beat the English gardener, and what seems to me of paramount importance just at this juncture is that the English gardener should have faith in his own ability, and more especially faith in his own climate and in his soil, and be bold and free to use his energy and energy to learn thoroughly the technique of special cultures, whether of fruit trees, vegetables, flowers, or bulbs. We want the intimate and special practical training that the Dutch bulb-growers turn to such a national advantage.

This is no new gospel, for the text itself has been preached from the days of Dr. Hallymore of Ely, in 1570, to those of Miller of Chelsea, in 1731. Miller, in his great *Gardener's Dictionary*, under "Tulip," especially recommends English growers to compete with those of France and Flanders, or Holland, in the rearing of these and other hardy bulbous flowers from seed. My present object is two-fold, and I wish to show that, cheaply and easily, he can do so. I wish to show that, and that the rearing of new varieties of bulbous flowers from home-grown seeds may be a most intellectual and interesting pursuit, whether it be profitable or otherwise.

It has been well said by many good authorities that English farming in the future will resolve itself into "gardening in the fields." That is to say, that at a time when corn and meat and wool can be imported as cheaply or more so than we can grow them for ourselves, then English soil wherever suitable may be best utilized in growing fresh flowers, fruits, vegetables, milks, and other commodities not so easily and cheaply imported. It may be profitable for us to grow such cultures, and that the rearing of new varieties of bulbous flowers from home-grown seeds may be a most intellectual and interesting pursuit, whether it be profitable or otherwise.

The soil, and especially the mild and early climate in South and West England, but the methods of culture there are generally of a very simple and ordinary kind. The same is true in some other parts of England, as in Lincolnshire, in many market gardens and nurseries near London, and in the Isle of Wight.

There are already hundreds of acres in Great Britain and Ireland under bulb culture, but there is room and demand

* At the very lowest calculation England pays £1,000,000 to the Dutch bulb growers every year.

for more. We may never export many home-grown bulbs, but so far as *Narcissi*, *Crocus*, and *Tulips* are concerned, we might easily grow our own supply. There are many growers here and there who are making a good living, even though not so fortunate, by careful bulb culture. As you go about through the country, and especially near most large towns, you see rows and strips of bulbs almost everywhere. Now that is a good sign, and though the cultivators do not stand shouting out to the passer-by as to bulbs being a paying crop, yet it is true all the same.

A man who is doing a good business in, as a rule, a sober and industrious man, content to eat a meaty bone in peace and quietness.

Let us ask what a bulb really is?

A bulb is simply a large bud, with closely packed fleshy leaves, or leaf bases, in which are stored an accumulation of starch, sugar, and other nutritious materials. These are for use as assimilating animals store up fatty matter before going to sleep for the winter, so do bulbs store up surplus food, and hide themselves underground, so as to go through cold or drought unharmed.

It is a habit renders bulbs so handy and convenient for distribution at certain seasons of the year. Bulbous plants are due to sudden changes of temperature, or of drought and moisture, such as occur in the great natural bulb fields of the world. These are in Southern and Eastern Europe, in Western Asia, in North Africa, and at the Cape of Good Hope. Briefly speaking, the climatic conditions, these are very cold or dry in winter, rainy and warm in spring, followed by a blazing hot and dry summer and autumn.

Hardly bulbs may suffer during a dry and hot spring, but they cannot well have too much moisture at the roots when in growth, and they enjoy warmth and drought when at rest. In order to grow bulbs to the best advantage for trade purposes, they must all be lifted and replanted every year. Here again we must follow out the good gardener's axiom of doing the right thing in the right way or manner, and at the right time. The bulbs must be dug or lifted as soon as the leaves turn yellow and fade, in June or July at latest. Above all dig too early rather than too late; dig before the leaves fade entirely, rather than after new roots grow from the base of the bulb. On most deep, rich, sandy soils, bulbs such as *Narcissi* and *Tulips*, &c., ripen off in June or July, and should then be dug, assorted, and cleaned ready for sale or re-planting. A light dry soil, and well-shaded, fitted with lath or open-work shelves, is convenient for storage; but much may be done with strong lath boxes that will stack one above another in field or garage, and which can be covered over temporarily when it rains.

The first thing is to select the most suitable to bulbs of various kinds. Even in Holland and other places where bulbs are and have long been a special culture, success can only be assumed on certain plots of suitable soil. Again, the land that grows the best *Hyacinths* is not so suitable for *Narcissi*, or for *Tulips*, even in Holland. I think the Dutch, in preference to the bulb culture, have turned to their methodical thrift and skilful industry—hereditary gifts—rather than to the super-excellence of their soils or their climate.

Where suitable land is to be had, and it is tolerably level, a slope followed by a three-pronged cultivator to loosen the sub-soil, may be used with economy, but in rocky plots on a steep gradient, and elsewhere on small areas, the spade is the best implement to use. Again, land, however good, will not grow bulbs year after year for ever, without manure or some recuperative rotation of cropping. On large bulb fields the ground is well cultivated, and well worked, with clover or Clover and Rye grass, and then well worked after these are garnered, for bulbs to follow. In any case, never till a crude or farinaceous manure direct for bulbs. Bone super-phosphates, and wood-ashes or kelp, may be worked into the soil with advantage a week or so before the bulbs are planted. I have also seen nitrate of soda and wood-ashes and soil used with advantage in February as a top-dressing.

(To be continued.)

MARKETS.

OOTENT GARDEN, MARCH 25. CUT FLOWERS.—AVERAHOE WHOLESALE PRICES.

Table with columns for flower types (Anemones, Armas, Bouvardias, Carnations, etc.), quantities, and prices. Includes a section for Orchids with prices for Cattleya, Odontoglossum, etc.

PLANTS IN POTS.—AVERAGE WHOLESALE PRICES.

Table listing plants in pots and their average wholesale prices. Includes Adiantum, A. plicatifidum, Aspidistra, Azaleas, Cinerarias, Cyclamens, Daffodils, Dracaenas, Evergreen Shrubs, Ericas, Hyemidias, etc.

FRUIT.—AVERAGE WHOLESALE PRICES.

Table listing fruits and their average wholesale prices. Includes Apples, Crab, Figs, Grapes, etc.

VEGETABLES.—AVERAGE WHOLESALE PRICES.

Table listing vegetables and their average wholesale prices. Includes Artichokes, Beans, Cauliflowers, Cucumbers, etc.

POTATOES.

The milder weather has somewhat checked demand, hence the tone is weaker. Dublin Maincrop, 75s. to 85s.; do., Saxons, 60 to 70s.; Lincoln Saxons, 50s. to 60s.; do., Maincrop, 55s. to 70s.; do., Glants, 48s. to 50s.; John Bull, Wellington, Scotch, Covent Garden.

THE WEATHER.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

Table with columns for DISTRICTS, TEMPERATURE, RAINFALL, and BROIST SUN. Includes sub-tables for accumulated temperature and other weather-related data.

The districts indicated by number in the first column are the following:—

- 0, Scotland; N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. Principal Grassing, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; Channel Islands.

BOOKS: A. A., F. M. M. How to Decorate the Dining, by Annie Hassard, and published in 1875, is sometimes to be picked up at second-hand bookshops for a few pence. It has illustrations of a bygone style of table decorations. A small book by B. C. Saward, price 2s., was published a good many years ago by Mr. Upcott Gilb, Bazaar Office, Strand, W.C. No book that we know of has been written solely on this subject in recent years. F. B. R., Messrs. Blackie & Sons, Glasgow and London, are the publishers of Thomson's Gardeners' Assistant, and they are about to issue a new edition of the work, with additions of various kinds, bringing it up to date. You had better wait a short time before buying one.

COMMENCEMENT OF THE SPRING SEASON: Ancients One. Astronomically, the season begins with the vernal equinox, March 21; but in this country the season may be said to begin on March 1.

CECUMBER SOIL AND WORMS: J. B., Burystone. A celerian has no worms discovered in box sent.

CYCLAMENS: E. M. Your flowers are very good in size and colour. No. 2 is an excellent dark-coloured variety.

GARDENIA GRANDIFLORA: A. Parry. Exceedingly fine large blooms. Bottom heat is not necessary in the cultivation of Gardenias, as you justly remark.

HYACINTHS: D. M. There is not the slightest sign of fungal disease, and microscopic examination has not enabled me to suggest any other cause. G. Massee.

INSECT: Elmora. We have received from the highest authority in such matters the following note:—"It is an immature species of thrips. I think G. C. crasipes; the more your friend has of them the better for him, it is beneficial, not injurious. It is a predatory creature, which was probably feeding upon something that is injurious—very likely has come from your correspondent's hot-beds. A. D. M.

MAIZE: A. M. O. There are a few varieties of Maize which in good years ripen in the southern parts of this country, but not as field crops, rather as inhabitants of favoured spots in sheltered gardens; but, as its ripening cannot be relied upon with certainty, the plant has no commercial value whatever. As an ornamental flowering plant it is of use in border and beds as a foil to flowering plants, and this seems to be its proper use in this country. In the kitchen as a cooked vegetable it does not seem to make any headway, although the "milky" cobs are very nice eating. It is, we suppose, because of the abundance of superior kinds of vegetables at the season when Maize is obtainable that we have not "taken it up." We should be glad to know the results of Carters' trials in their seed grounds at Mortlake. During last season there was much correspondence in these pages upon the subject.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—F. T. Lighton. A very fine variety of Dendrobium noble of the large-flowered type, often seen among recent importations. The production of the flowers-spikes on Cologeea cristata in the manner described sometimes takes place in unusually well grown plants.—N. S. Cattleya guttata Fritsch, more generally known in gardens as C. amethystoclossa.—G. E., Burnet. The variety of Dendrobium noble is a very fine one of the D. noble elegans class. The D. Wardianum obtained from Messrs John Cowan & Co., is a very large and distinct form, the rose-pink tips to each segment being a very distinct feature.—R. N. H. Oncidium Marshallianum.—W. T., Esler. 1, Forsythia suspensa, 2, Palmouria officinarum. (G. D., co. Waterford, 1, Peruetia mucronata; 2, Buxus variegata (variegated Box); 3, Guldstrandia

isophylla; 4, Anemone nemorosa; 5, Corydalis calva; 6, Saugauriana canadensis (Bloodroot); 7, Berberis Darwini.—H. G., Southampton. 1, Scilla giolla denticulata; 2 and 3, Campanulas—send in flower; 4, Lachenalia tricolor; 5, a Polygonum, for specific name, send in flower; 6, Clematis integrifolia; 7, Alonosa in floris.—J. W., Odontoglossum trichophyllum.—H. Woodwardia radicans cristata.—J. P., Dendrobium fimbriatum.—H. S., Narcissus Tazetta, Polyanthus Narcissus.—W. G., A very fine variety of Cyrtopodium Boxalli; the carrying of a twin-flowered inflorescence is more due to good culture than to anything uncommon in the plant; your variety, however, is an exceptionally fine one.—J. W. Two species of Acaecia (Mimosas of the trade) are grown in Southern Europe, viz. A. Farnesiana and A. Kiceana.—H. O. W., Ireland. 1, Pyrus japonica; 2, Cryptomeria japonica; 3, Juniperus excolta; 4, Prunus laurocerasus (Savage Laurel); 5, Cryptomeria elegans. NARCISSUS, Fern, etc.: J. H. Mason. The green tinge seen in the petals is natural to the variety. The Fern is probably Pteris tremula; but why send such a specimen? Unless the dung be very well decayed, it is totally unsuitable to mix with soil used in potting Ferns, and then only in a small proportion to the other ingredients of the compost.

PERFUME PLANTS TO GROW IN THIS COUNTRY: AND TOMATOES: S. H. W. Melissa officinalis (Balm), Carum Carui (Caraway), Sambucus nigra (Elder), for its flowers; Accorus Salusm (Sweet Flag), Foeniculum vulgare (Fennel), Pelargonium capitatum (Sweet-scented Geranium), Prunus laurocerasus (common Laurel), Lavandula vera (Lavender), Origanum marjorana (Marjoram), Reseda odorata (Mignonette), Rosmarinus officinalis (Rosemary). For varieties of Tomatoes, consult a seedsman's catalogue.

SOIL CONSTITUENTS AND MANURES: H. J. J. It would take us too far to tell you what all of the plants you mention contain, or of which an analysis would tell us they consist. They are built up by what they find in the soil, and to a greater degree of perfection when the particular elements needed are put within the reach of their roots. The soil, roughly speaking, contains lime, soda, nitric acid, magnesia, potash, phosphoric acid, and sulphuric acid. What the cultivator has to put into his land are potash, nitric acid, and phosphoric acid, because the available stores of these ingredients are soonest exhausted by continuous cropping of the land; and the only one of these three which is lost if his plants do not use it is nitric acid—the others remain in the soil. Sulphate of ammonia is used instead of nitrate of soda as a supply nitrogen to the crops; but it is dearer, and must be turned into nitric acid in the soil before it is a fit food for plants. None of these substances should be used alone, but a manure rich in phosphates should be used also; and in a small way you will find farmyard or horse-manure from stables where the animals' bedding is not very frequently changed, and phosphate of lime and old mortar as good as anything that you can use for the plants you name, excepting the Beans, which should have no nitrate of soda, and not much dung; and the Strawberries, which are plants that benefit greatly from applications of potash. (Only an analysis of the soil of your garden will tell you what artificial manures it most stands in need of.)

CONTINUED LARGE INCREASE IN THE CIRCULATION OF THE "GARDENERS' CHRONICLE."

IMPORTANT TO ADVERTISERS.—The Publisher has the satisfaction of announcing that the circulation of the "Gardeners' Chronicle" has, since the reduction in the price of the paper,

Increased to the extent of more than 90 per cent., and that it continues to increase weekly.

Advertisers are reminded that the "Chronicle" circulates among country GENTLEMEN, and ALL CLASSES OF GARDENERS and GARDEN-LOVERS at home, that it has a specially large FOREIGN and COLONIAL CIRCULATION, and that it is preserved for reference in all the principal Libraries.

THE
Gardeners' Chronicle.

SATURDAY, APRIL 3, 1897.

THE SPECIES OF THUYA.

WE are all agreed as to the beauty and utility of the several species of *Thuya*. As isolated specimens, as shelters, as hedges, even in one case, as to their value as timber-trees, we are all pretty much of one mind. When we come to nomenclature—*surgit aliquid amari*, as usual. But the bitter is not in this case very intense, nor is there much of it, and we think we can get rid of some of it altogether. There are not many species, to begin with.

In the eastern States of America and Canada, from Nova Scotia to Southern Virginia, according to Sargent, one—*Thuya occidentalis*—is found plentifully, frequently covering great areas of springy swamp-land, which it covers with nearly impenetrable forests, and occupying the rocky banks of streams, where its roots can obtain an abundant supply of moisture. The south does not suit it so well, the trees becoming less abundant and smaller in those regions. Its furthest north-west limit (we are taking these details from Sargent's *Silva*, just issued) is on the shores of Cedar-lake, near the mouth of the Saskatchewan, in lat. 53° 30' (Cochran, cited by Macoun).

A second species is *Thuya gigantea*, so-called. This occurs on the Pacific side of the continent from the coast region of Alaska (Meehan), through British Columbia, Washington, Oregon, and the Californian coast region. Inland it penetrates to the mountains of British Columbia, and to the western slopes of the rocky mountains in Montana.

A third species is a native of the mountains of Japan, and is best known as *Thuya Standishii*, being really *T. japonica*.

A fourth form, for we dare not call it species, is that cultivated in British gardens as *T. plicata*, which is as we believe more correctly, *T. occidentalis*, variety *plicata*.

A variety called *T. Wareana* is very like the last named, but is even more handsome; other seedling variations are very numerous, but these, for our present purpose, we may pass by with mere incidental mention, nor do we intend to say anything here about the eastern *Arbor-vitæ* (or *Biota*) and its numerous variations.

T. OCCIDENTALIS.—Reverting to the first on our list, *T. occidentalis*, it is not necessary to give a detailed description. That may be found in almost all the text-books. It was the first, or one of the first, North American trees introduced into Europe, the first account of it having been published by Belon (*Arb. Conf.*, 1558).

Mr. Smith has drawn to scale, and with the greatest care, illustrations of the cultivated forms, which will, we hope, make the distinctions more apparent (figs. 67, 68). Notice,

for instance, the regular way in which the branches divide into their ultimate flattish ramifications, nearly equal in length from the base to apex of the shoot; the older leaves, especially the median pairs, are relatively flat and rounded, like so many little coins, and with a large glob or resin-gland beneath the apex. The cones are from 10 to 12 mill. long, ovate-oblong, some erect, others nodding; the scales at least six, of which four are fertile, linear-oblong, with a minute hook-like process on the back below the apex. The seeds are about 2 mm. long, deeply winged.

Our native specimens are from Niagara; for cultivated ones we are indebted to the Botanic Gardens of Kew, Cambridge, Mr. Herrin, Mr. A. D. Webster, and many other friends.

As we have said, we do not propose to say anything at present about the very numerous

fast, that we can but highly recommend it, not only for ornamental purposes, but for economic use. We have not as yet heard of any serious foe or malady to which it is subject, but there may be such and we shall have to chronicle them when they do come.

“Considering the varied uses to which *Thuya gigantea* is put, it might well be styled “the Bamboo of the North-western Indians.” The bark is woven into mats, embroidered into lozenge-shaped spaces and borders, with bark of a darker colour, stained by steeping it in a mixture of oil, charcoal, and water. These mats are used in a variety of aboriginal modes of existence, and the manufacture is a marked feature in their domestic economy. The bark teased out is woven into blankets and cloaks, and used for gun-wadding. The wood splits easily, and forms boards for their lodges, and the trunks are hollowed out into their beautiful canoes. The twigs are so tough as to be used as withes to sew together the

FIG. 67. *THUYA OCCIDENTALIS*.

Real size; foliage magnified twice. The section across a branchlet and two leaves is magnified four times.

FIG. 68.—*T. OCCIDENTALIS*.

Young branches showing flattened, rounded leaves.

variations from the type, except in the case of that known as *plicata*, and even of that we shall defer further mention till we have dealt with the next species.

THUYA Plicata is also too well known to need detailed description, as under the name of *Thuya gigantea* or *Lobbiana* it is now widely distributed. The mode of branching is similar to that of *T. occidentalis*; the leaves are less markedly glandular than in *T. occidentalis*, and are more brightly shining, oblong, rounded, markedly acuminate, or deltoid acuminate, and not so flattened and disc-like, but varying in form according as they are placed on a fast or a slow-growing shoot. The cones are more generally pendulous, 15 mill. long (figs. 69, 70, 71, on p. 215).

This is one of the loftiest and most useful of trees in N. America, although the wood is soft and light; and it grows so well here in most situations, is so handsome, and makes timber so

detached pieces of the canoe, as well as to bind the boards of the lodges to the upright posts. The leaves are even smoked in tines of Tobacco fame. The bark is often used to roof temporary houses, and is a common material for canoe-scoops. The wood is almost indestructible underground, and it is extensively used in the construction of pickets or other works in which durability is required in the earth. It might be used much in railway sleepers, and, being, very light, might be easily wrought for window-sashes, doors, &c. It is one of the most beautiful trees in North-west America, and ought to be extensively planted in England. (Mr. Robert Brown's remarks as to the economic uses of *Conifera*, &c., made before the Edinburgh Botanical Society, April 9, reported in the *Journal of Botany*, vol. vi, 1868, p. 192.)

And this brings us back to the application of the name *plicata*. The history of this name is confused, but not uninteresting. A summary of it was given in our number for February 14, 1897, so that we need not here repeat the details. James Donn of Cam-

bridge, and David Don of the Lambertian Herbarium, have got very much confused over the plant. David Don, who published the first description of the plant in Lambert's *Pinctum*, folio edition (vol. ii., 1824), attributes the name *T. plicata* to James Donn, citing the sixth edition of Donn's *Catalogue*, p. 249. He might have gone back to the fourth edition, where the name occurs for the first time, not being present in the earlier editions. Being unaccompanied by any description, Donn's name is a *nomen nudum*. On this account we need not cite James Donn, as the species *plicata* must be attributed to David Don. The original specimen, gathered by Née, is in the British Museum. The history of Née has been alluded to previously (February 13, 1897). To the specimen is attached an inscription, which Mr. Britten has been kind enough to identify for us as being in the handwriting of David Don. It runs thus—"T. plicata, Nob." This then is the type specimen of *T. plicata*, D. Don in Lambert's *Pinus*.

The ascription of the species to New Spain seems to have been made in error, on the one hand no subsequent traveller has found the plant in Mexico; whilst on the other hand, Mezies found the same plant about the same time in Nootka Sound, and there are three or four specimens gathered by Mezies, Nelson, and Richardson in the herbarium of the British Museum. A comparison of these specimens with specimens of what is now known as *T. gigantea*, leaves no doubt whatever that they all belong to the same species, and that species, according to botanical usage, should be called *T. plicata*, D. Don. In gardens it may still be called *T. gigantea*, Hort., or Lobh's *Thuya*.

One point remains to be cleared up: where are the cultivated specimens of *T. plicata* which apparently existed under that name in the early part of the century? David Don alludes to "cultivated" samples, and James Donn includes them in his catalogue. The Cambridge Botanic Garden of those days exists no more, and Mr. Lynch tells me there is no old tree of *T. plicata* in the present garden; nor is there one at Kew.

Somewhere one would think there must be such a specimen. If not, it was very soon lost, for we find London in his *Arboretum*, p. 2458, mentioning plants in the Horticultural Society's garden, at Messrs. Loddiges, and elsewhere about London, which plants had every appearance of being only varieties of *T. occidntalis*. *M. T. M.*

(To be continued.)

NEW OR NOTEWORTHY PLANTS.

GALANTHUS CILICIGUS, Baker.*

My description of this new Snowdrop was drawn up from living plants sent to me by Mr. T. S. Ware, on January 7 of the present year. It was supposed to be *G. Fosteri*, but differs from that species by its less robust habit, much narrower leaves, narrowed gradually from the middle to a very narrow base, and by the want of the large green blotch over the lower half of the back of the inner segments of the perianth, which *Fosteri* has, in common with *Elwesii*.

I have just received dried specimens from Herr Karl Siegesmund, of Berlin, collected by Herr Walter Siehe on the Cilician Taurus in 1896, at an elevation of 560 metres above sea-level, with a note that it flowers from November to March. *G. Fosteri* is a native of the province of Siras, in north-eastern Asia Minor. The absence or presence of a green blotch over the lower part of the back of the inner segments of the perianth is, I believe, a constant characteristic, and it divides the spring Snowdrops in two groups, in one of which are *nivalis* and *elwesii*, and in the other *Elwesii* and *Fosteri*.

Bulb ovoid, $\frac{1}{2}$ inch in diameter; outer tunics

* *Galanthus cilicigus*, Baker.—Bulbo ovoido, spatia basali elongata; foliis 2-3 anguste linearibus pinnis viridibus; ovario turbinato; perianthi segmentis exterioribus oblongis marginibus medio-basis facie convexa, segmentis interioribus ovoido-emittis integris apice parum reflexis et renatis; areo nuda viridi spicali hypochrysi; sepalis plicatis, antheris apiculatis.

brown; basal spathe [reaching a length of 3 inches. Leaves 2 to 3, bright green, flat, narrowly linear, reaching a length of 5 to 6 inches at the flowering season, and a breadth of less than half an inch, narrowed gradually from the middle to a very narrow base; edge not recurved; back whitish. Peduncle as long as the leaves; spathe-valves lanceolate, under an inch long; pedicel short, cerise. Ovary turbinate, $\frac{1}{2}$ to $\frac{3}{4}$ inch in diameter; outer segments of the perianth oblong, concave on the face, $\frac{3}{4}$ inch long, $\frac{1}{2}$ to $\frac{3}{4}$ inch broad; inner segments of the perianth half as long as the outer, obovate-cuneate, emarginate, rather reflexed and crenulate at the apex, with only the apical horse-shoe shaped green blotch round the sinus. Anthers apiculate, reaching rather more than half-way up the inner segments. *J. G. Baker.*

WHY ORCHARD TREES STOP BEARING.

ONE has but to examine the foliage of almost any of our fruit trees in midsummer to discover that something is really necessary to the welfare of fruit-producers. The leaves are the lungs of the plant, and without favourable facilities for breathing—so to speak—the growth and vigour of the tree will be retarded. It takes two seasons to produce the fruit of an Apple, a Pear, or a Plum. The first year the buds are formed and matured; the next year these buds after expanding into blossoms in the spring, are developed into fruit during the summer and autumn. A certain amount of energy is required that the blossom-buds may be formed, and this, doubtless, often accounts for the alternate heavy and light crops of fruit on particular trees. The strength of the tree is required to mature the fruit, and the fruit-buds for another year are not formed, and only a small growth of new wood is produced. The healthy tree when resting a year regains its vigour, forms new buds, and is prepared to raise a crop of fruit the following season, to say nothing of having matured a fair growth of wood. A tree that is suffering from the devastation caused by insects, or from starvation, can no more mature a full crop of healthy buds to bloom the succeeding spring, than the tree that is loaded with a heavy crop of maturing fruit.

In the first place, it may be remarked that fruit trees should not be planted so thickly that sunlight is excluded from any portion of the foliage or of the fruit. Trees are frequently starved both for available food and a sufficiency of sunlight. Sometimes heavy doses of farmyard manure or compost are applied to orchards, but it may be observed that an excess of nitrogenous manure, of whatever kind, causes a rank, soft, long-jointed wood growth; while the trees, to produce fruit, should have short-jointed, solid, well-ripened wood.

To improve our orchards for fruit-bearing, it would be advisable to carefully cultivate the soil both under and around the trees, to apply chemical fertilisers supplying abundance of phosphoric acid and potash, and then to sow Clover. A crop of Clover would be obtained, which could be either fed off by sheep, or cut for hay; the roots of the Clover and stubble should then be ploughed under, which would yield by its decomposition available plant-food that could not fail but show itself in the future fruit crops. *J. J. Willis, Harpenden.*

THE FURNISHING OF CONSERVATORIES.

I was lately asked the following question, "Which is the best way to furnish a conservatory, by keeping the plants in pots, or by planting them out?" When the structure is of adequate dimensions to accommodate large plants, I think there are decided advantages in the planting-out system. Not only can a more natural effect be secured than is the case when plants in pots are exclusively used, but the plants may be preserved in perfect health with less labour. The conservatory, or winter garden, is most valuable when attached to, or in close proximity to the mansion, where, if artificially lighted, it may

be conveniently visited after dinner. It is necessary for the comfort of visitors that a warm temperature be maintained, and consequently plants that adapt themselves to this condition should be employed.

Many of the Palms lend themselves to this purpose, and the Kentias in particular are exceedingly handsome, *K. Fosteriana* and *K. Belmoreana* being the best, the latter is especially elegant, its fronds arch more, and are less spreading than those of the former. *K. Macarthurii* also makes a fine specimen, but is less elegant in appearance. The same remarks apply also to *Sesuvilla elegans*, *Hyophorbe (Arecia) Eanerii*, and *H. Verschaffelii*. *Hyophorbe lutescens* is a graceful Palm, which thrives well when planted out, although it is somewhat impatient of a low temperature. *Cocco plumosus* and *Calamus plumosus*, the latter having its slender stems and the ribs of its fronds beset with strong spines, answer to this treatment equally well, as does *Caryota urens* (the Wine Palm), which possesses a distinct appearance to any of the foregoing. Then, as a dense and rather dwarf-growing species, nothing is better than *Raphis tabelliformis*. Many others might be enumerated, but I prefer to confine these remarks to those that do well here. Such robust growers as *Sabal Blackburniana*, *Phoenix dactylifera*, and *Livingstonia chinensis* are too large for houses of ordinary size; while *Cocos Weddelliana*, *Geonoma gracilis*, and *Enterpe edulis* appear to be too delicate to succeed satisfactorily under this mode of culture.

From amongst other suitable plants the Musas must not be omitted, as these are ornamental, and very distinct in character from most other plants. Several of these, however, on account of quickly reaching a great height, cannot be well utilised except in lofty houses. *M. Esotea*, *M. paradisiaca*, *M. superba*, and *M. zebriana* are some of the best; *M. Cavendishii* and *M. coccinea* being good dwarf species. *Of Cordylines (Dracenas)* that may with advantage be employed in this way, *Draco, rubra, congesta, stricta, indivisa, fragrans*, and *f. Lindlei* should be included, although the last-named loses much of its beautiful colour when thus treated. *Aralia leptophylla* forms a fine object, and there are specimens here which when planted eight years ago were 3 feet high, but are now 20 feet in height, and have leaves 3 feet in diameter, with footstalks 4 feet long. *Brexia chrysophylla* grows equally free, but like the *Aralia*, is not often cultivated in this manner. *Picus elastica* and *F. e. albo variegata* are also useful, although, owing to the robust nature of the former, more than ordinary care must be exercised in finding a position for it. *Coffea arabica* is another desirable subject; its glossy foliage affords variety, and its fruit creates interest.

The following plants answer the purpose of filling open spaces beneath the taller plants, and can be easily replaced where it is found to be necessary:—*Carculigo recurvata*, *C. r. variegata*, *Aspidistra lurida variegata*, *Cordylone (Dracena) norwoodensis, terminalis, &c.*; *Monstera deliciosa*, *Pandanus utilis*, *P. javanicus*, *P. Veitchii*, *Zebriana (Tradescantia) pendula*, and some of the *Begonias*, *Ferns*, and *Selaginellas*.

I cannot find *Calamus plumosus* in any horticultural dictionary, but I believe it was introduced by Mr. Bull, of Chelsea, some twelve years ago; at any rate, we have an elegant Palm, which we received under the above name from a leading nursery firm. *Thos. Coomber, The Hoveley Gardens.*

METHODS OF PROPAGATION.

(Continued from p. 132)

ORNAMENTAL AND FOREST TREES FROM SEEDS.—Though, perhaps, more in the province of the forester than of the gardener, in small estates, the head-gardener has often the care of the woods and forests plantations; therefore, "Experience" will have a few words to say about this very important matter. As most of the trees which adorn and add value to our forests and woods are indigenous, the accepted method of raising is from seed. In the majority of cases, this requires no preparation previous to committing to the earth, but some are best prepared for this. Of the first, the most familiar is the Oak, which has

three British varieties, the peduncled-fruited being the most common, the sessile-flowered the next, and the Durmast—*Q. pubescens*—the least common. This has peduncled fruit, and seems to be intermediate between the other two. All three kinds are included under the name of "*Quercus robur*," in many books simply treating of forestry.

The most rapid grower, and the most widely distributed of the three, is *Q. pedunculata*, but the wood is paler in colour, and not so hard and durable as that of *Q. sessiliflora*, while *Q. pubescens* does not make a large timber-tree, and as it is generally found in damp boggy situations, may perhaps be the kind which furnishes the black wood used in cabinet work, and known as Bog Oak. The Acorns should be collected when they begin to drop, but must be allowed to thoroughly dry before storing, or they are apt to germinate prematurely, and thus become spoiled.

At the end of February, or early in March, draw drills in a sheltered piece of ground, about 4 inches

other barks. The Oak, standing singly, makes a noble tree for park or paddock. The timber is most valuable; while it may be grown in woods and coppices as an underwood stock, and will thrive in cold, clayey soils, where other trees but languish.

Another useful and most beautiful indigenous tree is the Beech (*Fagus sylvatica*), and this is raised in nurseries from its nuts or mast. In ancient times, when Britain was almost all covered with forest, the Beech-mast formed the food of the poor people, as well as innumerable swine, which roamed through the woodlands in an almost wild state, feeding on this fattening food, and also on acorns. On the Continent the poor peasantry collect the shed leaves of the Beech, and drying them carefully, stuff their palliasses with them, in lieu of straw. For this they are well adapted, being clean, elastic, and sweet smelling. The Beech-mast is collected when it falls in October, and is spread to dry in an airy place, and then keeps good and fresh till wanted. It is

crest in search of birds' nests, as though they had been brick walls. Mixed with Privet in the proportion of two to one, it forms a fine fence, but it is too shady for meadows or arable land.

(To be continued.)

BOTANICAL SURVEY OF THE CŒUR D'ALÈNE MOUNTAINS IN IDAHO.

The Division of Botany of the United States Department of Agriculture has just issued a most instructive report on a Botanical Survey of the Cœur d'Alène Mountains in Idaho during the summer of 1895, by John E. Leiber. As this region is heavily timbered, the economic part of the report necessarily deals largely with trees. Mr. Leiber has lived in Northern Idaho for about ten years, and during this period has often visited the Cœur d'Alènes, sometimes remaining there for several

FIG. 69.—*THUYA Plicata* (DOON, IN LAMBERT) = *T. GIgantea* (HORT.). Leaves magn. two diam.; cross-section four diam. (See p. 213)

FIG. 70.—*THUYA Plicata* (GIgantea, HORT.). To the left above, young female cones; to the right above, inner surface of scale with two ovules; to the left below, seed magn. thirty diam.; to the right, outer surface of scale, and section through scale and ovules. (See p. 213)

FIG. 71.—*THUYA Plicata*. Native specimen (See p. 213)

deep and 9 inches apart, and sow the Acorns in this, leaving about 2 inches from nut to nut, cover in lightly, and then tread along the top of the ridge, so as to make the soil firm around the seed. When the plow pushes above the soil, rocks and field-nice will give a little trouble. The former must be scared away, and the latter trapped by methods which are well known to most gardeners.

The young seedlings may be left in the bed till they are two years old, when they had better be shifted into the nursery quarters, where they may rest till they are from 5 to 6 feet high, requiring only to be cultivated between to cause them to make plenty of fine root-fibres, and so not be injured by their removal when finally planted out in park or forest. Generally twice as many or more are planted in a given area than are intended to stand, half being afterwards felled, and called by timber merchants "*Black-riads*," these furnishing small but useful timber for many purposes. If felled in April or May, the bark may be peeled off with facility, and is then most valuable to the tanner, as at this period it is rich in tannin, the active and useful principle in Oak and

usually sown in broad drills, about the same time as the acora, but may be sown more thickly, even broadcast; but drills are recommended, as the plan facilitates cultivation, and keeping free from weeds. I recommend somewhat deep sowing in March, as the nuts then soon germinate, and consequently the young plants get away from their enemies, for in addition to those that attack the acorns, the whole of the Corvidæ, from the raven to the jackdaw, and notably the handsome jay, as well as starlings, are very fond of Beech-mast, and the deep sowing is somewhat protective. If the soil of your seed-bed is light, the young seedlings will make plenty of root-fibre, and may be lifted and quartered out the year after raising. Beech, from the fact that the leaves are retained till pushed off by the coming young ones in the spring, make a capital sheltering hedge, where one is required to protect tender Conifers, Rhododendrons, or other half-hardy shrubs, and it is therefore used largely in nurseries, both here and on the continent, to form shelter for stool-beds. I well remember hedges of this character which were so dense and rigid, that as a boy I have walked along their

months at a time. His report, therefore, is the result of a large amount of observation and experience.

The discussion of the mineral resources of the region is pretty fully given, in order to show the scope and importance of the mining industries of this part of the country. Climate is dealt with in considerable detail, as in case of a future selection of any portion of this region for timber reservations, all possible knowledge of its climatic conditions will be valuable.

The report shows that the region is one of extremely heavy rainfall, compared with that of other localities so far from the Pacific coast; and that in consequence of this rainfall, an extensive growth of timber covers most of the region. The agriculture of the country amounts to almost nothing, and is confined chiefly to grazing.

One of the principal practical lessons brought out in the report is the extent to which forest destruction may be carried in the absence of any efficient legal or commercial check. The era of forest fires began in the earlier period of immigration, followed

by the destruction incident to the building of the Northern Pacific Railroad, and in very recent times by the unparalleled devastation connected with the mining industry.

The report closes with suggestions for a system of timber protection, drawn from the experience of Mr. Leiber of the region, the people, and of the local industries.

There is much valuable information for those of your readers interested in that country, *J. J. Willis, Herpanden.*

CULTURAL MEMORANDA.

CORREAS.

THE genus *Correa* was named after Jose Francisco Corre de Serra, 1750—1823, a learned Portuguese, who published several treatises on plant physiology, and consists of evergreen shrubs amenable to greenhouse culture in this country. A few of the best varieties are *C. cardinalis*, *C. magica*, *C. rosea superba*, *C. virens*, *C. bicolor*, and *C. pulchella*. If well managed, few plants flower more profusely or continuously than *Correas*, or are less subject to mildew. The plants may be struck from cuttings; but by employing *C. alba* as a stock, plants are more quickly grown from grafts, and specimens for exhibition produced in less time than cuttings would require to reach the same size. If a few plants only are required, it is better to buy them from a nursery, choosing healthy plants, well furnished at the base with shoots. If procured in the spring, and they are standing in small pots, repot them in the present month or in April, affording pots which are larger by 1 to 2 inches in diameter. The compost used in potting should consist of fibrous peat (not the hard kind), broken into pieces sufficiently small to drop between the ball and the side of the pots, adding silver-sand in sufficient quantities to make it porous. The repotted plants should be kept close for a few days. Whilst growth is active, they should be kept well supplied with water at the roots, syringing them overhead on bright days in the afternoon, and the ventilators closed before the sun is off the glass, but affording a little air for the night late in the evening. Plants which have flowered should be kept moderately dry for two or three weeks; and 1 shoots which have borne flowers shortened somewhat, leaving a well-shapen plant. I always place the *Correas* in the winter season in a light greenhouse having a night temperature of 40°. *J. H. C. S., Cheshire.*

ASTERS, STOCKS, AND ZINNIAS.

It is not prudent to sow the seeds of these plants too early, there being oftentimes a risk of the young plants being injuriously checked by being shifted from one place to another during the length of time that elapses before they are planted out of doors in May and June. Once checked, the plants seldom grow with freedom or flower satisfactorily. In the south, the first or second week in April is quite soon enough to sow for bedding-out purposes, and the plants thrive more satisfactorily than when seed is sown earlier. If but a few plants are required, seed should be sown in well-crooked pots or pans in a mixture of moderately light soil made firm by the hands, and brought to within half-an-inch of the rim. The seed should be scattered thinly, and very lightly covered with soil, which should be pressed smoothly, and then afforded water. One of the worst foes to the young seedlings is damping, which must be avoided by affording water in the morning only, and then only to those seed-pots that really need it. When a few true leaves are made, then prick off the seedlings at 2 inches apart in boxes or frames. Keep them rather close and shaded till they have recovered the removal, when more air should be admitted. It is important not to coddle these plants, but to grow them on gently and sturdily; and where a very large number is required, there is no better method than sowing in rows, thinly, on a mild hot-bed under a garden-frame. For later sowing, no bottom-heat is wanted, and disused Violet-frames answer well if the soil be lightly ricked up with a fork,

moistened thoroughly, and then afforded a dressing of suitable compost; the frames should be kept close, and shaded from bright sunshine till the seed begins to grow. Air should then be sparingly admitted for a time, and in a manner not to injure the seedlings by draughts. In cold weather, such frames should be covered at night. If seeds be thinly sown on these beds, no pricking-off is necessary, but they may go direct from the bed to the open border in cloudy weather. The *Zinnias* require a rich and deeply-worked soil, and considerable quantities of water in dry weather, and occasionally an application of manure-water. *H. Markham.*

FORESTRY.

THE VALUE OF WILLOW TIMBER.

WITH the greatly increased interest that has of late years been taken in our national game of cricket, the demand for Willow timber suitable for bat-making has, in consequence, been correspondingly great—indeed, at the present time it far exceeds the supply. This should be welcome news to those who are troubled about the agricultural depression at present prevailing, as on almost every country estate there are tracts of dampish ground suitable for the growth of Willows, but which are of little value for agricultural purposes. When we consider, too, that good "maiden" (unpollarded) Willow timber fetches readily 2s. 6d. per foot, that young plants are comparatively cheap, that the tree can be grown in damp lands where few other species succeed, and that it arrives quicker at maturity than most other timbers, no excuse need be offered for bringing the planting of the Willow prominently under notice. Probably no other tree receives or has received so small a share of attention as the pollarded Willow; while certainly no other can bear, without apparent injury, so much mutilation. The most profitable species of Willow to plant to grow into timber is *Salix alba* (white or Huntingdon), although, for special purposes both the Redwood and Bedford Willows (*S. fragilis* and *S. Russelliana*) may be strongly recommended. Even the timber of the Goat Willow (*S. caprea*), which, however, rarely attains to the dimensions of the others, finds a ready market for certain purposes, being tough and elastic, with a considerable lateral adhesion. When favourably situated, the growth of these Willows is rapid, and many which I have measured in a plantation had produced fully 40 cubic feet of timber in thirty years. But even this has been far exceeded, as will be seen by referring to the experiments conducted by the Duke of Bedford, where we find that 1½ foot of timber had been produced annually by the Willow for thirty years. In planting the Willow for profitable purposes, close order should be followed; and in one of the most valuable woods of this kind that I have examined, the original plants or cuttings had been placed at 3 feet apart, and not thinned before the shape of the trees became pronounced. The trees took the form of clean, branchless boles with heads not too spreading. Too much subsequent crowding must, however, be avoided, otherwise the trees become unhealthy, rendering necessary a careful and systematic thinning. Regarding the yield of timber per acre, I give the following figures taken from a plantation of thirty-five years' growth, where the soil was a rich, unctuous yellow loam—far too good to be put under such a crop. The plantation was rather gappy, due, I should say, to careless thinning done at irregular intervals of time, the average distance at which the trees stood apart being about 18 feet, 140 trees thus going to the acre. In order to compute the contents, five fair-sized trees were measured, the average amount of timber being found to be nearly 52 cubic feet; at which rate an acre would produce 4480 feet, which at the reasonable figure of 1s. 6d. gives £336. It must be remembered that the plantation had received many thinnings, but for how much money the timber thus cut out had been sold, or what was the total quantity, no record had been kept. Let us, however, suppose that the value of the previous

cuttings paid the estimated letting value and taxes, cost of planting, and general upholding of the wood-land, and we have then left a clear profit of £9 per acre per year—a handsome return from even good Wheatland. But not only for the best class of cricket-bats is Willow timber in demand, but, owing to its teasing rather than splintering, it is largely used for the bottoms and sides of carts and barrows, for the floats of paddle steamers, for breaks on waggon and trucks, and largely for turnery purposes. It is very light for its bulk, tough, easily polished, and, comparatively speaking, incombustible. *A. D. Webster.*

TREES AND SHRUBS.

PRUNUS MUME.

CONSIDERING that this is one of the most popular of flowering trees in Japan, it is strange that it has, until quite a recent date, been almost unknown in European gardens. It belongs to the Apricot section of *Prunus*, and the wood is very like that of the common Apricot. The leaves, too, plainly show the affinity with that species, but they can be recognised by the much longer, drawn-out point. The flowers began this year to open about the middle of February, but it is towards the end of March that the general crop appears. They are produced on the leafless wood, much after the fashion of the Almond, each flower being about 1 inch across. The colour is rosy-pink, in some forms of so pale a shade as to be almost white, whilst in others it is quite rich and deep. The species has long been a favourite tree with the Japanese, and under their cultivation has varied considerably. Besides the varieties in colour just mentioned, there are others with double flowers, or a pendulous mode of growth. In this country it will be welcomed as an addition to the earliest of spring-flowering, hardy trees—a group that can never become too plentiful.

PRUNUS DAVIDIANA.

In this beautiful tree we have the forerunner of the great host of Peaches, Almonds, Cherries, &c. (now collectively known as *Prunus*), whose flowers during the next two or three months contribute so much to the beauty of English gardens and woodlands. A few of its flowers were open in the middle of January, but the great bulk of them were held back by the short spell of frost. Now, however, a few mild sunny days have brought it fully into bloom, and very lovely it is, especially the white-flowered variety (*alba*), which appears to flower more freely than the deep pink one (*rubra*). Its slender, rather erect branches are now completely wreathed in pure white blossoms. It is of Chinese origin, and was first sent to Europe by the Abbé David, a French missionary. It is common in the gardens and roadsides about Peking, and at its flowering season is a most beautiful and conspicuous sight, holding there, apparently, a position in public favour analogous to that of the flowering Cherry (*P. pseudocerasus*) in Japan. In this country it ought in time to become as well known and popular as the Almond, belonging, as it does, to that small but welcome group of hardy trees and shrubs whose flowers appear soon after New Year's Day, and thus anticipate by several weeks the majority of spring-flowering trees and shrubs. *W. J. B.*

DAPHNE LAUREOLA AND D. MEZERUM.

D. laureola is a native shrub, although somewhat rare in a wild state. It is desirable for shrubberies and similar positions owing to its delicate perfume, which closely resembles that of *D. indica*. The greenish-yellow flowers are freely produced, but are comparatively insignificant; and on warm, moist evenings in February and March, a stranger would be puzzled to know from whence the delightful fragrance proceeded. It has a much more refined scent than that of *D. Mezereum*, and I consider it more penetrating. The flowers are followed by an abundance of bright red berries, which are said to be very poisonous; and for this reason the plant should be kept out of the reach of children.

It is described in Bentham's *British Flora*, dated 1878, as having scentless flowers, and bluish-black berries; this does not agree with my experience, but, as a rule, I find the scent is absent until an hour or two before dusk. It reproduces itself freely from seeds here, and in that respect differs much from *D. Mezereum*, which hitherto has failed, although many plants of it were introduced by the late Mr. Ingram

here, 40 feet long and 10 feet wide, the plants being about 2 feet high, and in full flower on Feb. 24. At such a period of the year it would be difficult to find any hardy plant to equal it for beauty and fragrance. Two distinct shades of red were noticed, one much darker than the other. There is said to be an autumn-flowering variety, but I do not know it. *W. H. Divers, Belvoir Castle Gardens, Grantham.*

of soda is now £9 per ton. Commercial ammonium sulphate contains about 24.5 per cent. of ammonia, this is equal to 20.17 per cent. of nitrogen; commercial nitrate of soda contains about 15.5 per cent. of nitrogen. From these figures, it will be seen that we can buy the same quantity of combined nitrogen in the form of ammonium sulphate for 7s. 9d. as we can for 11s. 7d. in the form of nitrate of soda.

Another point in favour of ammonium sulphate is the ease with which any adulteration can be detected. Pure ammonium sulphate, if placed on a hot iron plate, will be more or less volatilised, the amount of residue left behind is an index of the amount of impurity. The impurities occurring in nitrate of soda are not so readily detected. Both salts are easily soluble in cold water. The effects of each salt are nearly identical upon plants, because ammonium sulphate is changed into nitrate in the soil, and is then absorbed by the crop. Where great leaf-growth is needed, ammonium sulphate is most useful. It gives good results when applied to Cabbage, Leeks, Parsley, Lettuce, Endive, Celery, and Potatoes. It should only be used sparingly for Onions and Turnips, as the bulbs are not enlarged in proportion to the leaf-growth, and they do not keep so well if too liberally treated with ammonium sulphate. Ammonium sulphate is useless for Peas and Beans. No objection can be raised to the employment of a solution of ammonium sulphate for watering salad-plants, as it is a clean salt, whereas the use of filthy liquid-manures for salad-plants is to be condemned as dangerous and nasty. When applied to young plants with tender foliage, or to plants in pots, it is better to use it in dilute solution about two ounces to a gallon of water. One ounce to a square yard is enough for one dressing on the open ground.

For gardens smaller quantities are required than for farms; but even if 9s. per cwt. is charged for this salt, it will be found profitable. Most gasworks now make ammonium sulphate instead of selling the ammoniacal gas liquor. The nitrogen in bone-manures, in guano, in fish-meal, and in the much-advertised mixtures, costs very much more than that in ammonium sulphate.

It must always be borne in mind, however, that it only supplies plants with one important substance, i.e., nitrogen; further, its effects do not persist for more than one season—what the crop does not absorb is washed out of the soil in the form of nitrate by the winter rains. All soils are rendered more fertile by its use. *F. V. Dutton, University College, Bangor.*

TULIPA KAUFMANNIANA.*

This Tulip was discovered by Albert Regel in the mountains of Turkestan, and was described and figured by his late father in the *Gartenflora*. Anyone who compares the original figure with that now given (fig. 72) will be surprised at the astonishing difference which a few years of cultivation have made. The "potentialities" of a flower can indeed rarely be estimated from the wild plant. This Tulip belongs to the woolly-bulbed series, generally with two leaves. The flower-segments are oblong elliptic, or in the cultivated plant, oblong obovate obtuse, variable in colour from pale pink to pale rosy-purple.

It was shown at the last meeting of the Royal Horticultural Society, by Messrs. Wallace of Colchester, and Messrs. Barr of Covent Garden.

PLANT NOTES.

ASCLEPIAS CURASSAVICA, *Leon.*

An attractive, soft-wooded plant, common about the coast districts of Grenada, and a favourite food-plant of the caterpillar of a rather large brownish butterfly, which is known in the local vernacular as "Soldat Martinique"; it is also much frequented by a pretty marked plant-bug. The upper portions of the plant (stems, leaves, and flowering stems), discharge a white fluid when cut. It flowers when a foot or two

* *Tulipa Kaufmanniana*, Regel, *Gartenflora*, 1877 (t. 906).

FIG. 72. TULIPA KAUFMANNIANA.

at various times. I am now experimenting with it in different soils and situations in order to arrive at the cause of failure, if possible. The figure of Mr. Marshall's fine plant on p. 153 almost made me envious, and I well remember some large plants of the pink and white varieties when I was a boy in Kent. Occasionally, one sees small plants in the cottage gardens in Leicestershire; and lately I saw a bed of seedlings in one of our home nurseries near

AN ECONOMICAL TOP-DRESSING.

THE GREAT fall in the price of ammonium sulphate makes this substance now the cheapest source of nitrogen. Twelve months ago it was quoted at over £12 per ton; to-day, it is offered at £7 17s. 6d. per ton. When it was at the former price, it was more profitable to buy nitrate of soda; the price of nitrate

high, and rarely attains many feet at any time of its existence. The orange-coloured flowers are admired by most people, especially by strangers to the West Indies, and the plant is often mistaken by the casual observer for *Lantana Canara*, Linn., because of the colouring of the flowers, and general habit when the latter-named plant is small. Both plants grow in similar localities, and, in fact, occasionally may be seen growing side by side. Our wild *Lantanas* enjoy with the wild *Crotons* of the colony the same name, i.e., "Wild Sage." In Dicotyledonous plants the natural order *Asclepiadaceae*, to which *Asclepias curassavica* belongs, is the only one that possesses flowers with their stamens and pistils adhering, and such is the case with *Orchidaceae*, in Monocotyledonous. The *Asclepiad* under notice would make a desirable bedding plant for tropical flower-beds. Its local name is "Ipecaea." *H. E. Broadway, Grenada, March 4.*

THE WEEK'S WORK.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorset.

Odontoglossum-house. — In this house *Maxillaria grandiflora*, *M. venusta*, *M. picta*, *M. lepidota*, *M. striata grandiflora*, *M. luteo-alba*, *M. tenuifolia*, *M. Amesiana*, *M. prestans*, &c., thrive admirably; and it is now the time when an examination of these plants should be made. If some of them require large pots, or the potting materials are decayed, the present is a suitable season to attend to these matters. The following species of *Maxillaria*, viz., *M. Sanderiana*, *M. incata*, and *M. Hübschii*, are showing for bloom, and re-potting in their case will have to stand over for the present. *Maxillaria Turneri* and *M. nigrescens* are species that succeed in a cool part of an intermediate-house. All species of *Maxillaria* mentioned above may be cultivated in pots or in shallow pans, three parts filled with crocks, and in a compost consisting of three parts sphagnum-moss, and one part peat. Repotted plants must be shaded from strong sunshine, and afforded only just as much water as will keep life in the sphagnum moss, till such time as growth begins; and when they get well rooted, plenty of water at the root and moisture in the air should be supplied.

In the *Cattleya*-house, plants of *Pleiocha maculata*, *P. m. alba*, *P. lagenaria*, *P. precox*, *P. Valliciana*, and *P. concolor* are growing vigorously, and will require plenty of water at the root, and their immediate surroundings kept decidedly moist. An occasional watering with weak liquid cow-manure will be of great assistance to them. These plants should occupy the coolest part of the house, and where air can be freely admitted, and scarcely any shade is necessary, unless the sun be very powerful. The cooler-growing varieties—*P. humilis* and *P. Hookeriana*—may be repotted as soon as they pass out of flower. The *Calanthe* compost will suit them admirably. They should be suspended in a light position, close to the roof-glass in the *Odontoglossum*-house.

Temperatures.—The month of April is generally a very troublesome period to the Orchid cultivator, owing to the numerous changes in the weather, which make it difficult to maintain regular temperatures in the houses. Still, the most must be done by attention to the heating apparatus, and to shading and ventilation, to avert excessive fluctuations. In such changeable weather it is best to keep the hot-water pipes a trifle warmer than usual, even during the middle of the day, and when the sun becomes suddenly obscured by heavy clouds the ventilators may be closed and an extreme fall in temperature prevented. No further fire-heat will be necessary in the cool-house, unless the temperature of the house is likely to fall below 50°. When the wind is chilly, the proper degree of warmth should be regulated by means of the ventilators. The temperatures of the various divisions as maintained by fire-heat should now be as follows—East Indian-house about 65° through the night. The *Cattleya* and Mexican-houses 60°; Intermediate-house 55° to 60°; *Odontoglossum*-house a trifle above 50°. During the daytime a rise of several degrees above these figures is advisable, and a further increase of 5° or 10° by sun-heat will do good.

Shading.—Owing to the exceptionally dull autumn and winter the foliage of the plants is more tender than usual, and therefore more susceptible to injury

from the sun's rays. For instance, we have a large plant of *Dendrobium Dalhousienum*, which was exposed to plenty of full sunshine throughout the whole of last summer, but during the past week several of its leaves have been severely scorched. The plant is in the same position exactly as it was last year, which proves that the injury was not caused through any flaw in the glass. On that side of the East Indian-house where such plants as *Cypripediums*, *Bolles*, *Phalenopsis*, *Angrecums*, *Aerides*, *Saccolabium*, *Bulbophyllum*, *Cirrhopteralum*, *Phaius*, *Dendrobium Ituntoni*, *D. McArthur*, *D. O'Brienianum*, *D. rhodostoma* × *D. tridactylum*, *D. purpureum*, *Ocoidium Kramerii*, *O. papilio*, *O. ampliatum*, &c., are grown, the blinds should be lowered immediately when the sun has sufficient power to raise the temperature 6° or 7°. Where such species are arranged on the lighter side, as *Dendrobium*, *Catantemus*, *Cynoches*, *Mormodes*, *Thunia*, *Schomburgkias*, *Cryptopodium*, *Grammatophyllum*, *Brassavola*, *Renanthera*, and the warm-loving *Epidendrum*s, it is also necessary to use considerable caution. The blinds of the *Cattleya* and intermediate-houses should be laid down before the sun has become strong enough to overheat the leaves of the plants. The plants in the Mexican-house enjoy the early morning sunshine, but as the temperature rises by this means, ventilate freely, and when the foliage of the plants becomes white to the touch, lightly shade them. When this is likely to produce a rapid fall in the temperature, the ventilation should be reduced. Now that the majority of these so-called Mexican plants are starting to grow, the house should be closed early in the afternoon, including plenty of sun-heat; but thoroughly moisten the floors, stage, &c., at the same time. *Odontoglossums*, *Masdevallias*, *Maxillarias*, *Oncidium*s, and the other occupants of the cool-house, should be shaded on bright mornings immediately the sun has raised the temperature to 55°, and the blinds should not be removed so long as the sun is on the roof. The roller-blinds that are now used for shading Orchids admit plenty of light, so that there is no necessity to keep taking them up and down at every trifling change in the weather, as was necessary when the ordinary canvas-blinds were in use. Therefore, when the weather is changeable, keep the blinds down.

FRUITS UNDER GLASS.

By F. HARRIS, Gardener, Eastnor Castle, Leicestershire.

Strawberries.—British Queen will come on quite fast enough if the plants be put into a cold-frame finally. Let the plants be afforded water early in the morning so as to get the leaves dry before nightfall. This variety sets freely in frames, and if the plants are placed later on a shelf in a cool orchard-house close to the ventilators, the fruit will come of great excellence, and before the early outdoor-varieties begin to ripen. If mildew be observed on any of the plants, dust the foliage with flowers-of-sulphur, and spray it off in a day or two afterwards.

Pines.—Plants which showed fruit very early in the year, and are now approaching maturity, will require considerable attention in the matter of water at the root, and putting stakes to the fruit. Liquid-manure, at a temperature of 90°, should be afforded them so long as the fruits remain green; afterwards manure-water should be withheld almost altogether, and clear water only afforded when the soil gets very destitute of moisture. The bottom-heat should be raised to 85° or 90° for fruiting plants, and top-heat at 70° to 75° at night, rising 10° by day with fire-heat, closing the fruiting-house early, so as to husband solar-heat, allowing it to rise to 95° or 100°. Afford atmospheric moisture abundantly, damping paths, walls, and the bed between the pots twice or thrice daily. When the fruits begin to ripen, keep the air a little drier. Later fruiters will require similar attention in staking, &c. The best method of supporting a fruit in an erect position is to place two strong stakes on either side, an inch or so from the rim, and pass a strong piece of matting from one stake to the other, with the fruit in the centre, the matting coming round the base of the crown, as the tuft of leaves is called. Suckers, except one, or at the most two, that may be required for keeping up the stock, should be removed before they become large, as well as every growth appearing at the base of the fruit. In removing root suckers, do not give a straight upward pull, which might lift the plant out of the soil, but with a sharp twist detach the sucker without disturbing the plant in the least.

Successions.—If these plants were put into fruiting-pots in February, they will now be making growth.

Let the bottom-heat touch 86°, and no higher. Do not let them get crowded; rather re-arrange the plants, and afford each the utmost amount of space possible, and in doing so keep them well up to the glass by the addition of a little new or old bark, as the case may demand. When affording water, let it be thoroughly done, so as to wet every part of the soil, and let plenty of air into the house whenever the solar heat is powerful and admits of its being done, but avoid draughts—not an easy matter at this season of bright sun and cold winds. Hexagon netting several times folded and hung over openings and ventilators is of use at this season in breaking up volumes of cool air, and rendering it less objectionable to tender plants. It is just as good hung over the back openings of hothed frames, as over the ventilator and window openings of pineries, peacheries, and vineries. It should be remembered that the ventilation of plants at this season wants the greatest degree of watchfulness on the part of the gardener and his assistants, and that nothing can be left to chance, a few minutes neglect ruining perhaps the work of an entire year. In giving air, always do so gradually, so as not to lower the temperature of a structure all at once; and the same rule should be observed in taking it off.

Suckers.—The February-potted suckers are making roots, and should consequently be afforded water more freely than heretofore, and as they grow allow extra space, otherwise they will become drawn, a condition from which they never will recover. The temperature of the pit should range from 60° to 65° at night, and that of the bed about 75°. On very bright days shading will be required by suckers and successions, and a slight overhead sprinkling at closing time; but in this matter the gardener should be guided by local conditions, for what is demanded in one part of the country is unequalled in another. If the stock of any variety is deemed insufficient and suckers are available, these may be twisted off the parent plants, and in two or three days afterwards potted in 4's and set in the sucker-pit to root.

PLANTS UNDER GLASS.

By G. H. MAYCOCK, Gardener, Laton Hoop Park, Luton.

Paeonies.—Those plants which have been during the winter in cold frames may be removed to a low house or heated pit, in order to avoid the damping-off of the blooms as much as possible. Pieces grafted on roots of *P. officinalis* last year will do best if still allowed to remain in an unheated frame from which frost is excluded. They should be examined, and the growths tied to sticks, taking care in doing this not to twist the scion, or failure to unite may occur.

Paeonia carnea.—This is a winter flowering plant, not so much cultivated as formerly, but still very useful at this season, its flowers lasting a long time when cut; and the plant when grown in 5-inch pots forming good subjects to place in vases, &c. in the dwelling. If growth for cutting purposes only, or for decorating the stove, a 7 or 8-inch pot should be used. If cuttings be taken the first week in April, and dibbled into a mixture of leaf-mould and sand in equal proportions under a bell-glass, and placed in the propagating-house, they soon form roots. The plant grows in a mixture of one part loam, one part leaf-mould, a small portion of dried cow-dung, with sufficient sand to keep the mass porous. The shoots should be often stopped so as to increase their number, and prevent the inherent tendency to grow tall and lanky. They should be kept, when of small size, near to the light in the stove or stove-pit.

Primulas.—Seedlings should be pricked off into shallow pans filled with a rather light compost of peat, leaf-mould, sand, and loam; and a sowing may be made for succession. The double-flowered varieties of any kind may now be increased by division of the roots: being careful to have a few roots with each piece. Pot-up these divisions in light soil—sphagnum-moss and much sharp sand, and plunge them in a gentle hot-bed till such time as the roots take hold of the soil, then remove them to slightly cooler quarters in a frame similarly to the seedlings of single-flowered varieties. Cuttings of double-flowered varieties can be rooted in sphagnum if kept close and moist on mild bottom-heat. The divisions and cuttings, when establishing themselves, should receive water sparingly.

Hints on the Fertilization of Plant Houses.—As every gardener knows, no plant can be grown at its best unless kept generally free of those insects which are parasitic upon it, more particularly thrips, aphides of various sorts, and red-spider. That being well understood, the first appearance of these insects

on any plant should warn the gardener of the necessity of his aid at once taking steps to rid the plant of them. It is a far easier matter to destroy the fore-runners than a numerous host; there is, therefore, economy in taking early measures against the enemy. If it is but a few plants, these should be removed to a warm or cold pit, and be there fumigated at a small cost; but if it be a whole house full of plants that have to be dealt with, the house should be kept drier and ventilated to a later hour than usual, and the fumigation commenced after the sun has left the house. If aphid only has to be destroyed, one mild fumigation will suffice to kill all the mature insects, but it should be supplemented with a second one in forty-eight hours, so as to destroy the later hatched brood, tobacco-smoke being useless against the aphid-egg. Thrips, both black and yellow, require from two to three fumigations at intervals of one or two days, and the amount of smoke generated should be denser than is required to kill aphid. I do not advise the immediate syringing of the plants after fumigation, as it tends to revive many of the dying insects.

Water-flowing Begonias.—Cuttings may now be taken, striking them, one in a 60-pot, on bottom-heat of 80°, in light, rich compost, and putting them on when rooted without loss of time. Aged Begonia plants, which may have been cut down to afford shoots for making cuttings, may be potted in 7-inch pots after a sufficient number of cuttings has been secured. They are useful in the decoration of the conservatory, and supplying bloom for cutting.

General Remarks.—The following seedling plants should be pricked out before becoming crowded in the seed-pots and pans:—Gloxinia, Begonia, Torenia, and Streptocarpus. Cyclamen will require to be potted in thumb-pots and 6's, keeping them afterwards in a partially-shaded place. Caladiums intended to flower in pots should be repotted, and afforded for a time a slight amount of shade from bright sunshine. Impatiens Sultanii may be increased by means of cuttings. It is an attractive plant when flowered, and the cuttings strike freely in heat at this season. When struck, pot on and keep them in a warm, moist stove-pit, and close to the glass, to prevent lanky growth being made.

THE FLOWER GARDEN.

By CHARLES HERRIN, Gardener, Dropmore, Maidenhead.

Sowing Annuals.—Various annuals, such as Stocks, Asters, Zinnias, Phlox Drummondii, Salpiglossis, Galliardias, and others, should be sown forthwith. For raising these in a better medium can be employed than in frames or pots upon a mild hot bed. Given abundance of fresh leaves, they will answer admirably, and a strong heat is not necessary; a bed to the depth of 3 feet will be ample, the leaves to be well trodden down in the process of making. Work in a little long manure round the sides, to hold the mass together, and prevent the leaves from pushing out when treading and working upon the bed after it has been made up. After putting on the frames, place a few inches of leaf-mould in the bottom, and on this about 3 inches of light soil that has been passed through a half-inch sieve. The surface of the soil when finished should be within a few inches of the glass. Put the lights on, and leave them for a few days until the soil has settled and become warm. Before sowing, draw out shallow drills, 3 inches apart, and cover the seeds at a depth according to their size. The frames should be kept closed and shaded until the seedlings appear, when the shading should be gradually removed by using it during bright sun for a few days only. Admit air in greater quantities as the seedlings develop, to prevent them becoming stumpy. Zinnias and Galliardias make useful bedding plants, and if the beds are empty in which they are to be planted, they may be lifted carefully from the seed-frame early in May, and planted at once, shading with a few branches for a day or two if the weather be bright. Stocks and Asters may be treated in the same way, or be pricked off into other cold frames or sheltered borders as soon as strong enough to handle. The seeds of Salpiglossis are small, and must be covered slightly, and the seedlings be transplanted carefully to the borders, as they are not free-rooting plants.

Calceolarias struck and wintered in cold frames now require to be transplanted, and a bed of soil should be prepared on a hard bottom of coal-ashes, either in cold frames or where protection can be given. The plants should be lifted with a trowel, and re-planted about 1 inch apart each way.

The soil should be loamy, with an admixture of half rotted leaf-soil or old Mushroom-bed manure. They will then be lifted with good balls of soil, when transferred to the flower-beds. Where the latter are now empty, and shelter can be afforded with mats or canvas if necessary, Calceolaria plants may be put into the beds now, and if planted thus early into their permanent quarters, they will become established before hot and dry weather sets in, and consequently they will be less liable to die off during the summer.

Notes for summer bedding may receive somewhat similar treatment to the above, except that no protection need be afforded. Where these are to form the ground-work of beds during the summer, they should be put out now, if possible, and all flowers be kept pinched off for some time to come. One of the best dark blues for summer flowering is Archie Grant, and a good white will be found in Mrs. Gray.

Gauldians.—All named varieties should be got into the ground now as soon as possible. Where they are to be planted in lines, drills 3 inches in depth may be drawn out, a little sand scattered in, and the corns set out at convenient distances in them. Beds filled with Carnations may have a few corns dotted about in them, and they will give a furnished appearance to the beds after the Carnations have flowered.

THE KITCHEN GARDEN.

By W. PORE, Gardener, Highclere Castle, Newbury.

Celery-sowing and Pricking-out Seedlings.—If seed for the main crop is not yet sown, there should be no further delay in sowing. Sow the seeds thinly, and afford the seed-pans genial warmth to induce speedy germination; but as soon as the plants are through either the soil, or into cooler quarters, and afford them plenty of sunlight and fresh air, and pricking them off when the first true leaf develops. Do not let pricked-off plants, or those still in the seed-pans, lack root-moisture, or suffer from overcrowding at this stage, these often being causes that bring about bolting. A pinch of Celery-seed may be sown on a south border, in order to furnish plants for late and spring uses.

Carrots.—The sowing of the main crop may be made when the weather and state of the ground permit. James's Intermediate is still a favourite Carrot with many gardeners because of its smaller size as compared with the New Intermediate or St. Valery; and, unless exhibition roots are required, it is preferable for general consumption. The new variety is larger, has a better colour, and is a handsome root. The land for this crop should have been well manured for some previous crop, or it has been recently dressed, the manure should have been placed at the least 1 foot deep. Sow the seeds in dry soil 15 to 18 inches apart, and 1½ inches in depth, and after covering the seed, and before raking the land, afford it a fair and regular dressing of soot and common agricultural salt. In order to have roots fit for exhibition on heavy land, holes should be made with a long dibber or crowbar to a depth of 15 inches, and the same distance between, filling these with finely-sifted soil, to which a small quantity of fresh soot has been added, pressing it firmly into the holes, and sowing a few seeds in the middle of each. A bed of Sutton's early Gem, or early Nantes Carrots, may be sown at intervals of three weeks till August. The later sowing affording nice roots far into the winter, which, for many purposes, are more useful than large roots. Pay attention to the early sowings in frames, thinning them early to from 3 to 6 inches, according to variety, and admitting plenty of air to the frames in mild weather, and not letting the soil get dry.

Turnip-rot Beet.—A sowing of Egyptian or Turnip-rotted Beet, and one of Pragnel's Exhibition for early consumption, should be made, but do not sow the main crops for several weeks.

Potato Planting.—The planting of the Main Crop and late varieties of Potatoes should be pushed on when the land is dry enough to be workable. If the land is already dug, and is fairly light and dry, the sets may be inserted in holes made with a blunt-ended dibber, otherwise digging and planting may be done simultaneously—a method generally to be preferred if care be taken to pulverise the soil generally, and not merely the surface. Allow sufficient space for the haulm to develop without undue crowding; and as the strength of the haulm varies in the different varieties, this will have to be considered by the planter. Small growers, as Ashleaf and Sharp's Victor, may be planted at 24 and 12 inches and

bigger growers at correspondingly wider intervals, the largest being 30 by 21 inches. Medium growers are Windsor Castle, Supreme, and Sutton's Seedling. If manure is applied when planting, it should be thoroughly rotted, such as that from a spent hot-bed, and is the better if it consists chiefly of tree leaves. This should be spread in the winter, and at planting time a good sprinkling of wood-ashes, dissolved in water, or a Potato-manure be applied, and the dressing repeated before earthing up the plants.

THE HARDY FRUIT GARDEN.

By H. W. WARD, Rayleigh, Essex.

Dealing with Insect Pests.—With the gradual increase in the outside temperature, aphid will seek to attach themselves to the young growths of the Peach, Cherry, and Plum trees, inflicting much damage to the trees if prompt measures are not taken to prevent them. Weakly-growing trees are more subject to the attacks of insects. Sometimes it is the conditions under which the tree's growth is made that predisposes it to insect attacks. It may be that the soil about the roots is not in a condition to promote and maintain strong growth. When the attack is clearly indicated by the leaves becoming curled, it is difficult to dislodge the pests by the application of clean water with a syringe or garden-engine. Hence the necessity of taking remedial measures on the first appearance of either the green or black fly, the latter being the more mischievous, as well as the more difficult of dislodgment. Especially is this so in the case of Cherry trees, which the black aphid mostly infests, and sometimes to such an extent as to render necessary the dipping of the tops of the shoots in a saucer containing Richards' XI. ALL Liquid Insecticide, a composition which I have also used with the best possible effect by means of a syringe, in the proportion of one part of it to thirty of water. Another good insecticide is clean water and tobacco-juice, used in the proportion of 1 quart of the latter to 4 gallons of the former.

Grafting Apples and Pears (in the manner described in the *Gardeners' Chronicle* for February 27, p. 138) may still be done. Examining grafts worked during the past month, and replace the clay round those from which it may have fallen off, filling up at the same time any cracks that the recent parching winds may have caused in the clay round others. In some cases it may be necessary to tie a little fresh moss over the clay in order to preserve it and the graft in an uniformly moist condition by damping it occasionally with water.

Thinning Apricot Fruits.—Where the trees have set heavy crops of fruit, no time should be lost in effecting the necessary thinning. In the case of healthy, vigorous-growing trees, the fruit may be thinned out at once to 6 or 8 inches apart each way. There need be no fear of such trees dropping their fruits during the process of stoning, providing the soil is kept in a properly moist state around the roots.

Strawberry Plantations.—Keep plantations of Strawberries free from weeds, and should dry weather continue, plants growing in light and perhaps shallow soils should receive applications of water at the roots.

THE APIARY.

By EXPERT.

Robbing.—For a few weeks to come great care will be required if signs of robbing are apparent, not only in protecting the particular stocks which may be attacked, but also in preventing the mischief from spreading to other hives; this may be guarded against by carefully observing the movements of the flying bees while inspecting stocks. Should it be seen beyond doubt that robbing is going on, close all hives except the one which is being operated on during the time it is uncovered, not more than five minutes, and when the quilts are replaced, re-open all entrances for a couple of minutes to allow the bees to settle themselves, then close them again, and proceed as before, with the hive furthest away from the first examined. Do not re-confine the bees which have been overhauled, because opening the hive will cause a little excitement, and they should have free egress while this lasts. Where sliding entrances are used, they can be effectually closed and re-opened in an instant, so that very little time is taken up, and the plan will be found useful in checking robbing in its early stages. Brush off debris from floor-boards into a newspaper and burn.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction in these pages, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR APRIL.

SATURDAY, APRIL 3	{ Societe Francaise d'Horticulture, London Isle of Wight Horticultural Society
WEDNESDAY, APRIL 7	{ Shropshire Horticultural Society's Spring Show Royal Calcuttian Horticultural Society's Exhibition, Edinburgh (two days).
SATURDAY, APRIL 10	Royal Botanic Society's Meeting.
TUESDAY, APRIL 13	{ Royal Horticultural Society's Com- missioners (National Anticilia and Primaia Society), at Drill Hall.
THURSDAY, APRIL 15	Lincoln Society.
SATURDAY, APRIL 24	Royal Botanic Society's Meeting.
TUESDAY, APRIL 27	Royal Horticultural Society's Com- missioners.

SALES FOR THE ENSUING WEEK.

MONDAY, APRIL 5	{ Anemones, Roses, Gloxinas, Bego- nias, Spireas, &c., at Frotheroe & Morris' Rooms.
TUESDAY, APRIL 6	{ Established and imported Orchids, at Frotheroe & Morris' Rooms.
WEDNESDAY, APRIL 7	{ Japanese Lilies, Carnations, Green- house Plants, Roses, Gladioli, &c., at Frotheroe and Morris' Rooms. Choice Roses and Palms from Ghent, Border Plants, Fruit Trees, &c., at Stevens' Rooms.
THURSDAY, APRIL 8	{ Border Plants and Bulbs, Roses, Shrubs, &c., at Stevens' Rooms.
FRIDAY, APRIL 9	{ Established and imported Orchids, from Messrs. F. Sander & Co., at Frotheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—46° 9'.

ACTUAL TEMPERATURES:—

LONDON.—March 31: Max., 54°; Min., 39°
PROVINCES.—March 31 (6 P.M.): Max., 45°, Jersey and
Scilly; Min., 38°, York.

It has been placed to the credit of the late Emperor of BRAZIL that on being shown the fly-wheel of a certain steam-engine, and informed that it made over 300 revolutions per minute, he remarked that it was far ahead of his country, for they could only muster that number of Revolutions in a year; and so of Greece it may be remarked that many have had the Revolutions during the past hundred years, especially in Crete—one of those—

“Isles of Greece,

Where burning Sappho loved and sung.”

and to-day the whole of Europe and Great Britain is exceedingly perplexed as to what is to be the order of things in Crete, and in Greece itself, in the days to come. We can

only express the hope that freedom and prosperity may be the outgrowth of the present imbroglio, for then horticulture and agriculture will flourish on this borderland of the East. As to the resources which those two are capable of yielding in freedom and peace it were difficult to say. The island lacks proper cultivation, is thinly populated, its exports are limited in value and number—olive oil, wine, raisins, soap, Locust-beans, Valonia, Almonds (shelled), and some Oranges. The islanders do not profess to be great statisticians—perhaps it would be nearer the truth to say that the Turk does not bother much about such things as statistics; hence our Consular agent in Crete, Sir A. BILLOTTI, finds it exceedingly difficult to get at the truth in all such figures as relate to exports and imports, only those immediately engaged in carrying to and from the fair little island being able to give reliable information on quantities and values—completeness not being guaranteed. Every time there is “disagreement” between Turk and Cretan, there is destruction of Olive-trees, Vines, carobs, and farm products generally. To-day the news is just the same—looting, lawlessness, and wanton destruction. Vineyards, orange-groves, olive-plantations, are not the growth of a season, and one need not wonder to learn that husbandmen get disheartened, and throw in their lot with other workers in other places. Of the products now shipped from the various Cretan ports, a fair proportion finds its way to this country—in the shape of olive-oil, raisins, Locust-beans, Valonia.

Manchester supplies a fair amount of the imports; Greece, Turkey, Austria, and Germany, being comparatively near neighbours, being the remainder of the trade. Says Sir A. BILLOTTI:—“Articles of exportation are paid to merchants cash down. They receive in their stores the agricultural or industrial products of the peasants, who are at liberty to leave them in deposit up to two years, and sell them at their convenience within that period. In return, they pay interest at the rate of 9 per cent. on all sums advanced to them by the merchants.” Stocks of olive-oil, &c., are sometimes kept in hand for a couple of years to get a good regular price. The Olive crop has been notable for the alteration of good and indifferent crops, so that the marketing system is evenly profitable. Should peace follow the present chaos, we cannot doubt that agriculture will rapidly come to the front, and most certainly a fair amount of British capital will find its way to this long-suffering land.

NYMPHÆA LEYDECKERI.—This is another of the beautiful hybrid hardy Water Lilies raised by M. LATOËR MARLAC, of which we have already given other woodcuts. Our illustration (fig. 73) was taken from a plant grown in the lake at Gunnersbury House, Acton, by Mr. HUDSON. The leaves are heavily blotched with dark purple, and the flowers are of a delicate pink colour. Messrs. VEITCH tell us that May and June are the best months for planting. They need no further attention than keeping the ponds free from weeds. It is not advisable to plant these Water-Lilies in lakes tenanted by swans, or in those infested with water-rats.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—At a meeting of the Committee of the Gardeners' Royal Benevolent Institution, held at the offices, 50, Parliament Street, S.W., on Friday, March 26, the following Resolution was unanimously adopted:—“The Committee of the Gardeners' Royal Benevolent Institution desire to place on record an expression of their deep regret at the severe loss

they have sustained by the death of Dr. HOGG, Chairman at the Anniversary Festival Dinner in 1876, a Vice-President, and a Trustee. For the long period of fifty-five years, Dr. HOGG had taken a keen and active interest in the work of the Institution; he always had its welfare at heart; and his warm support will be greatly missed. The Committee further desire to express their sincere sympathy with Mrs. HOGG and her family in their bereavement.

AN ORCHID COMMITTEE FOR MANCHESTER AND DISTRICT.—A circular bearing the signature of W. A. GENT, 44, Faulkner Street, Manchester, the purport of which is the formation of a committee dealing with Orchids, has reached us lately. It runs as follows:—“At the instance of several gentlemen in the surrounding district, it has been thought desirable to form an Orchid Committee with headquarters in Manchester, composed of amateurs or private growers, as separate and apart from the Orchid Committee of the Royal Horticultural Society. An entrance-fee of three guineas, and an annual subscription of one guinea thereafter, is suggested; but this and other matters are subject to the approval of the meeting to be called at an early date (of which due notice will be given), your attendance thereto being cordially invited. It is estimated that within a radius of thirty miles of Manchester the Orchid wealth of the country is centralised; this fact is generally recognised by many people interested in their culture, and I shall be very glad to receive the assurance of your support to the project herein referred to.”

SECRET TRADE COMMISSIONS.—The Council of the London Chamber of Commerce has recently appointed a Special Committee to inquire into and report upon the subject of “the pernicious practice of giving and receiving secret trade commissions.” A preliminary meeting was held on the 2nd ult., when Mr. DAVID HOWARD, one of the Vice-presidents of the Chamber, was elected Chairman, and Mr. WALTER HAZELL, M.P., Deputy-Chairman. In order that the committee may have the fullest information before it, the Council desire to make it known that the Committee are willing to receive and consider confidentially any evidence or information on the subject which anyone may be disposed to bring before it. Mr. KENRIC B. MURRAY, the Secretary, invites confidential communications, to be addressed to him by letter, or to be made to him verbally, to be held before the committee, and to say that no communication or information will be given to the committee without the previous consent of the party forwarding the same. Any information which may be given will be treated in the strictest confidence, and no names or particulars will, unless authorised, be allowed to transpire even in committee.

ABERDEEN.—An association is being formed, at the instance of the General Council of the University of Aberdeen, for the purpose of diffusing information regarding the wants of the University, and of collecting funds, and applying the same to purposes tending to promote its efficiency as a seat of learning. In the enumeration of the more pressing wants of the University, the second place is given to “a botanic garden, and funds for its maintenance;” and among the lectureships suggested, “forestry” holds a good place. Already a large and influential number of gentlemen have become members of the association, and the names are still coming in. It is sincerely to be hoped that Dr. JAMES W. H. TRAIL, Professor of Botany in the University, will soon have one of his pet schemes carried out—the establishment of a botanic garden.

GOURD FESTIVAL.—During the sojourn of the QUEEN at Nice, she is reported to have visited the square in front of the monastery of Cimiez, to see the annual Gourd festival. The QUEEN examined with interest the painted and decorated Gourds, and purchased a certain number. Will some Riviera correspondent kindly give a little further information about this festival?

FIG. 73.—*NYMPHEA X LAYDEKERI*: FLOWERS PINK. (SEE P. 220.)

THE NURSERYMEN, MARKET GARDENERS, AND GENERAL HAILSTORM INSURANCE CORPORATION.—The directors submitted to the shareholders the second annual report on the business of the Corporation for the year ending February 23, 1897, together with the audited accounts. The Corporation was registered on February 23, 1895, as a limited liability company, with an authorised capital of £100,000. The first issue was 5000 shares of £5 each, all of which have been applied for and allotted, and 10s. per share have been called up and received. The directors drew attention to the gratifying fact that, not only has all the issued capital been subscribed, and the number of subscribers increased, but also that the income has been largely augmented, whilst the working expenses have been less than in the previous year. The agencies all over the country have been increased to seventy-two, and the directors would be glad to receive applications from gentlemen who would undertake agencies in districts not yet represented. The directors draw attention to the special advantages of insuring with the Corporation, the loss of glass by hail being immediately made good at the rate per square foot at which the glass was insured. The contents of glasshouses are likewise insured, an advantage offered by no other insurance office.

REVENUE ACCOUNT.

Income.—The income from premiums amounted to £89 11s. 5d., which—with dividends derived from investments, £54 6s. 1d., and £49 13s. brought forward—made the total income, £393 10s. 6d.

Expenses.—The total sum charged against revenue was £679 9s. 10d., consisting of the following items:—

Commissions on insurances	492	8	1
Working expenses, including secretary's salary	194	1	9
20 per cent. written off formation expenses (£309 1s. 4d.)	...	80	0
10 per cent. written off office furniture and fixtures (£49 7s. 8d.)	...	4	0
Reserved for unexpired risks	...	300	0

BALANCE SHEET.

Capital and Liabilities.—Shareholders' Capital:—

5000 shares of £5 each	...	25,000	0
Called and paid up, 10s. per share	...	2,500	0
Shareholders' surplus	...	5	0
Balance of revenue account	...	223	8

Assets.—Of the paid-up capital, after deducting balance of formation expenses and cost of furniture, £185 10s. 7d. is invested in 2½ per cent. Consols, amounting at cost price to £151 6s. 6d., £300 in 3½ per cent. Liverpool Corporation Stock, costing £197 13s. 6d., and £500 City of London 2½ per cent. debentures, costing £255 13s. 6d. The remainder is included in the cash at bankers.

The directors recommended the payment for the year of a dividend to shareholders at the rate of 5 per cent. per annum on the paid-up capital free of income-tax, amounting to £102 13s. 6d., and they suggest that the balance of revenue account, after setting aside £300 for unexpired risks, be dealt with as follows, viz., set aside £100 to create a reserve fund, and carry forward the sum of £29 2s. 2d.

Deep regret was expressed on the death of Mr. James Wessley, of Covent Garden, one of the trustees of the corporation. It will be necessary, therefore, to elect a Trustee to fill the vacancy.

"THE DAHLIA."—In this handy little volume published at a shilling by Messrs. MACMILLAN, Mr. CUTBERTSON has condensed a great deal of information concerning the history, botany, propagation, cultivation, and exhibition of the Dahlia, together with a catalogue of varieties, and an article on the future of the Dahlia. Mr. CUTBERTSON has had as his associates, Messrs. RICHARD DEAN, JOHN BALLANTYNE, STEPHEN JONES, and ROBERT FIFE, so that readers of the book may be well confident that the information is accurate and up to date. One thing surprises and disappoints us. A few years ago, the Royal Horticultural Society, the late Mr. SHIRLEY HIBBERD, and some at least of the horticultural press, were at great pains to collect and co-ordinate all the available history of the Dahlia. A Dahlia congress was held, papers were read and published, costly illustrations prepared, and the whole thing was worked out from the point of view of the cultivator and of the botanist as well as it could be, but, so far as we can see, little or no use or even mention has been made of this treasure-house of facts. The great, and we believe increasing popularity of the Dahlia originated

when single and Cactus Dahlias began to oust the ugly inelegant monsters pilloried in orthodox green stands. Nothing in its way can exceed the exquisite beauty of colouring of the show Dahlias, but the way of exhibiting them, except, of course, for purposes of adjudication, is even worse than in the case of the Rose. The Rose is so exquisite, that, however exhibited, it is still beautiful, which only a few devotees can admit to be true of the Dahlia under like circumstances. Happily, of late a more excellent way of showing Dahlias has become popular, and their great decorative value been made apparent.

THE HORTICULTURAL TRADE OF THE ISLAND OF BUTE.—On Tuesday the 23rd ult., the Marquis of BUTE, the Provost of Rothesay, opened a new Post Office in that town. Hon. Sheriff MACKENZIE, in his speech at the opening banquet, thus referred to the gardening industry carried on in Rothesay and neighbourhood:—"The only considerable trade now is the trade of market gardening and the raising of seeds and plants. Coincident with the decay of other trades he had mentioned, they had this very important trade rising up amongst them. Without making any invidious comparisons, he might mention that of the dozen or so firms engaged, one—that of Messrs. DONNIE & Co.—had risen to a very important position in regard to the trade of the kingdom in its own department. In one year they had sent out no fewer than 140,000 parcels, &c., through the post office, at a cost of £1500 for postage alone. It was a trade which seemed to suit the genius of Rothesay, and they proved it by carrying on a business which depended so much on geniality of weather and good soil."

NEWCASTLE-UPON-TYNE FLOWER SHOW.—We have received the schedule of prizes to be offered by the Durham, Northumberland, and Newcastle Botanical and Horticultural Society on the occasion of the summer show, to be held in the Recreation Ground on July 8, 9, and 10. A special Victorian prize-class has been arranged for a collection of Rose blooms set up in water and named, arranged for effect, upon a space of 10 feet by 1 foot. Palms, foliage-plants, Ferns, and moss may be used at the discretion of exhibitors. The 1st prize will be one of the Society's gold medals and £12. The schedule in other respects is very similar to previous ones from Newcastle, liberal prizes being offered for plants, cut-flowers, table decorations. Fruit and vegetables, in open classes and limited ones. A good show may be anticipated.

THE TIMBER SUPPLY OF THE BRITISH EMPIRE.—Under this title, Dr. SCHULZ, Professor of Forestry at the Royal Indian Civil Engineering College, Cooper's Hill, delivered a lecture at the Imperial Institute on Monday evening, March 22. A table showing the imports of timber into Great Britain, and giving other details, had been prepared and circulated, and upon this the Professor prefaced his remarks. The lecture was more or less of a statistical character. Dr. SCHULZ referred to the enormous amount of mischief done in the cutting down of young trees in the Scandinavian forests for the wood-pulp industry, and also to the serious havoc caused by forest fires, especially mentioning Canada, where ten times the amount of timber has been destroyed by fire than was ever cut. With a proper forest conservancy, the lecturer looked upon Canada as the safest source for the future timber supply of the world. He strongly recommended the planting of waste lands in Scotland and Ireland to provide work for the surplus population. No reference was made to any possible substitutes for the timbers now in commerce. In the table of statistics before referred to, Dr. SCHULZ gave, under Mahogany, 262,713 as the value of Mahogany imported from West Africa during the year 1894, but he omitted to mention the important fact that the true Mahogany (Swietenia Mahogany) is not found in Tropical Africa. There are several trees which furnish the so-called African Mahogany, and so far only one has been satisfactorily determined, namely, the

Calleedra, or Mahogany tree of the Gambia (Khaya senegalensis). The tree furnishing "Abeku," or Gold Coast Mahogany, is a Sapotacea, the seeds of which are occasionally imported into this country from the West Coast as an oil-seed.

HAMBURGH GENERAL HORTICULTURAL EXHIBITION.—It is officially announced that Baron SCHROEDER of The Dell, Egham, intends to exhibit a number of Orchids at one of the early shows; the space required by the plants being about 50 square yards. This proof of his old attachment to the town of Hamburg, and sympathy with the objects of the great undertaking, is greatly appreciated.

"BIBLIOTHEQUE D'HORTICULTURE."—Under this general title M. OCTAVE DOIN, 8, Place de l'Odéon, Paris, is publishing a series of small hand-books on horticultural subjects by various writers. They are published at a price to bring them within the means of the thrifty amateur, and so far as we have tested them, they appear to be excellent. They are too numerous to notice individually, especially as being written in the French language they will appeal to a limited number of our readers. We give the titles of some that lie on our desk, and can, without hesitation, recommend them to those who read French:—*Les Rosiers (Roses)* by COCHET-COCHET and S. MOTTEY; *Culture des Fougères Exotiques (Culture of Exotic Ferns)* by ADOLEPHE BUYSSENS; *Colecolaires, Cincéaires, Coléas, Hélotropes, Princeses de Chine, &c.*, by JULES RODOLPHE; *Les Géraniums, (Polargonum, oncle et nequins)*, par H. DAUTHENAY; *Les animaux utiles et nuisibles à l'Horticulture*, creatures useful to or detrimental to horticulture (insects excepted), by ALB. LARBALETRIER. In general treatment these little books agree. There is a slight botanical history of the genus, very well done, a systematic account of the principal groups and of the most important species, details concerning their culture and propagation. The volumes are freely illustrated, but some of the illustrations are worn as with long service. Some, such as that devoted to Roses have an index, others have only a *table des matières*, which is by no means a substitute for an index. The treatise on the animals which co-operate with the gardener, and those which are more or less of a nuisance to him, is also well done, but too condensed.

JAPANESE BAMBOO.—The following extract upon this subject is taken from the *Journal of the Society of Arts* for March 26:—"Bamboo and Bamboo wares constitute an important item in the miscellaneous export commerce of Japan. Bamboo for shipment abroad is grown in districts adjoining Kyoto and Osaka, and in Shikoku and in Kyushin, the varieties differing somewhat, according to localities. In Hiroshima the black and the spotted varieties grow; the former is produced in Kochi, also in many parts of Kyueiui. Bamboo grown in Yamauchi, Oita, and Ehime belong to the cheap varieties. The cultivation of black Bamboo is carried on extensively in Kochi, where a *tan* (a quarter of an acre) of Bamboo yields 30 to 60 yen per year. Bamboo is exported to most countries of Europe, and also to America and Australia. The bulk of the Bamboo shipped from Kobe—from which place nine-tenths of the total are imported—goes to England, the varieties being black, spotted, and white. To France and Germany the black and white sorts of the best quality are shipped; while long, bleached, angling Bamboos are in demand in New York."

"FERNS AND FERN CULTURE."—Mr. J. BIRKENHEAD has issued a second edition of his very serviceable little book, which may be had from the author at the Fern Nursery, Sale, near Manchester. Great attention is given to the preparation of composts and the methods of cultivation and propagation. That Fern roots have "mouths" by which they take up moisture is a statement that the botanist will not accept. We cordially commend the little book to the notice of those who are beginning the culture of Ferns.

LEE, BLACKHEATH, LEWISHAM, AND WEST KENT HORTICULTURAL SOCIETY.—The successful series of monthly lectures which have been held by this body of gardeners at the Instituto, Old Road, Lee, was brought to a close on Friday, March 26, Mr. H. J. NETTLEFOLD presiding, when a lecture, by Dr. B. CRANE, Esq., Highgate, was read on "The Artistic Arrangement of Cut Flowers in Vases, Epergnes, &c." Mr. JUDGE, who, in the absence of Mr. CRANE, read the paper, brought some Orchids, including a fine plant of *Dendrobium Wardianum* giganteum.

"THE LARVÆ OF BRITISH BUTTERFLIES AND MOTHS."—The Ray Society has published the seventh volume of the series of descriptions and illustrations of the larvae of British butterflies, comprising the first portion of the *Geometre* prepared by the late WILLIAM BUCKLER, and edited by Mr. G. T. PORRITT. The illustrations, mostly by Mr. BUCKLER, are excellent, the text full of information, so that as a reference work it will, like its predecessors, be indispensable in entomological libraries.

MR. DOUGLAS.—The members of the National Caranion and of the National Aurielia Society propose to testify their esteem for their late secretary by presenting him with a striking memorial at the luncheon at the Hotel Windsor on April 13.

ROSE SHOWS IN THE JUBILEE WEEK.—Mr. E. MAWLEY, Honorary Secretary of the National Rose Society, writes: Local considerations having rendered any day in the Diamond Jubilee week impracticable, the date of the National Rose Society's Southern Show, at Portsmouth, has been changed from Wednesday, June 23, to Friday, June 18.

READING AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.—The usual fortnightly meeting of the above society was held in the Clubroom, British Workman, on Monday evening, March 29, and was largely attended. The President, Mr. C. B. STEVENS, occupied the chair. Apart from the lecture, the feature of the meeting was a presentation to the honorary secretary, Mr. POUND, as an acknowledgment of services rendered to the association, and an album, containing the names of 138 subscribers. Proceeding with the usual routine of the meeting, the president called upon Mr. TOWNSEND, gardener at Sandhurst Lodge, to read his paper on "Summer Bedding and Summer Flower Gardens, also the Water Garden." The plants recommended by the lecturer were *Fuchsia*, Ivy-leaved *Polargonium*, *Lobelia cardinalis*, *Verbena*, *Petunia*, *Viola*, fibrous-rooted *Begonias* (such as *Sutton's Crimson Gem*, *Princess Beatrice*, and *Afterglow*), *Ajuga reptans*, *Phlox Drummondii*, *Mimulus*, *Gladiolus*, *Cineraria maritima*, *Ricinus Gibsoni*, *Maize*, *Salvia* (*Sutton's Scarlet Queen*), *Marguerites*, *Heliotrope*, *Euoxygenia radicans variegata*, *Zinnias*, *Habrothamnus*, *Erythrina*, &c. As materials wherewith to plant a border, mention was made of *Cupressus*, *Juniperus*, *Acer*, *Hollyhock*, *Asters*, *Cannas*, *Ricinus*, *Hydrangeas*, *Liliums*, tuberosus *Begonias*, leaving spaces for the introduction of tender plants and annuals as the warmer weather approached, as herbaceous *Phlox*, *Delphiniums*, *Cannas*, *Lupines*, *Lavatera*, perennial *Sunflower*, *Dahlia*, *Rudbeckia*, *Pyrethrum*, *Lychnis*, *Sweet Rocket*, *Spiraea*, *Montbretia*, *Lobelia cardinalis*, *Gypsophila*, *Picotees*, *Carnations*, *Calceolarias*, *Asters*, *Sweet Williams*, *Mimulus*, *Aubrietia*, *Zinnias*, *Goletias*, *Funkias*, *Begonias*, &c. Reference was made as to the grouping of pot plants about the lawn by inserting the pot to the rims in the grass. This is carried out in Sir W. FARRER'S garden at Sandhurst Lodge, and greatly admired. *Fuchsia*, *Plumbago capensis*, *P. c. alba*, *Solanum jasminoides*, *Habrothamnus* and *Swainsonias* lending themselves admirably to this purpose. The water-garden was then touched upon, the lecturer dealing with the various plants most suitable for different sized ponds. A beautiful collection of florists' varieties of *Cineraria* was sent by Messrs. SUTTON & SONS, and of *Cineraria cruenta* hybrids, also specimens of *Cineraria cruenta*.

THE HAMBURG EXHIBITION.—One feature of the Hamburg Exhibition will be a large tank lighted and warmed for exotic Water-Lilies; among them, yellow, blue, and red *Nymphaeas*, and *N. zausiberosus*, will be included. There are, now-a-days, many new varieties of these plants, and among prominent exhibitors who have devoted much attention to them may be mentioned MM. KAESTER DE SPEYER, who will contribute in stocking the tank, as will the Hamburg Botanic Garden. Outdoor aquatic-plants will be represented; M. TRIBAUT LYAN of Geneva will contribute specimens occupying 100 square metres of water.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held on Monday, April 5, 1897, when a paper will be read by Mr. WALTER SIMMS (Fellow), entitled "London—an Appreciation." The chair to be taken at 8 o'clock.

PUBLICATIONS RECEIVED.—*Nederlandsche Maatschappij Voor Tuinbouw en Plant-Kunde* (Netherlands Horticultural Society). List of Certificated Plants in 1896.

WEST BANK HOUSE, HEATON MERSEY.

THE owner of West Bank House, John Leemans, Esq. (gr., Mr. Edge), has put up, on the most approved principles, a splendid range of glass, in which he has collected a general assortment of ornamental plants—Orchids forming a notable feature. Like most amateurs who favour Orchids, Mr. Leemans began by collecting with cheap popular plants, until further experience showed him how desirable it was to buy the choicer species and varieties. In this well-appointed establishment, where everything is kept in apple-pie order, I can see another of our rising Lancashire establishments, where gardening of the ornamental kind, both indoor and outdoor, promises to be of as prominent a character as a fine gallery of pictures, where the eye of a connoisseur is held. The position is on a slope, with nice undulations, and the breezes play freely in the tiered span-roof glass erections. They are fitted up with all modern appliances to suit the growth and comfort of the various subtropical and temperate-zoned plants—fitted up, too, with electric-light, and those Teak blinds which the writer recommended in the pages of the *Gardeners' Chronicle* more than a quarter of a century ago, after seeing M. Luddemann's Phalaenopsis so blinded about the environs of Paris, and which are now very generally used in all Orchid establishments. Of the particulars of these, and of the grounds, in the meantime, we do not mean to touch, rather going into somewhat of detail about the conservatories attached to the mansion-like villa on the crest of the hill.

The conservatories are in three tiers—that is, on three levels—an arrangement that is partly due to the slope of the ground. They are attached to the billiard-room, and are accessible from others without going out-of-doors. While they are lofty, they are not too much so for the plants and the light from the span-roof reaches even the smallest plants. In the principal portion are a fine lot of *Camellias*, and some of the fragrant greenhouse or rather intermediate-house *Rhododendrons*, as well as specimen *Azaleas* and miscellaneous plants standing on the tessellated floor, and some from the ornamental stages, which go well together with the bulbous and ornamental plants that are provided in relays from the other service-houses.

Orchids in flower are grouped on a stage in the inner circle adjoining the billiard-room, and formed a very pretty show at the time of my visit. Among *Dendrobiums* were some striking forms of *D. nobile*, from the white form of the *Cypheri* type, and *D. nobile nobiliss.* Among the choicer ones we observed *D. Cybele*, which is a much larger flower than the very similar *D. nobiliss*, although not so highly coloured; *D. Wardianum* in abundance, and the white form of it seen here was a very good one. For varying and adding to the finish of a group of

Orchids, nothing is better than *Cymbidium lowianum*, with its rich variety of colours.

A very fine form of *Cattleya Trianae* alba was noticed, a good square flower, with finely-femored petals of good substance; the lip large and round, and but for the slight flushing in the extremity of the blade, which proved it was not an albino, it would be put into the first rank. *Odontoglossum crispum* and *Miltonia Roezlii* were species observed in faultless condition. A plant of *O. cirrosum* was in fine flower; also the bright yellow and chestnut blotched *Oncidium sacrodes*. The *Cypripediums* are very select. I noticed a remarkable *C. Boxalli*, with fringed segments, heavily spotted with black, and a good *C. villosum* species, which remain a long time in flower. J. A.

NARCISSUS ELLEN WILLMOT AND SOUTHERN CROSS.

THE two pretty varieties of *Narcissus* of which we afford our readers delineations, were raised by that successful cross-breeder, the Rev. G. H. Engleheart, of Appleshaw, Andover. The variety *Ellen Willmot* belongs to the *Ajax* section, and possesses a creamy-white perianth, consisting—as fig. 74 shows—of comparatively short, broad segments; and the corona is lemon-yellow, the two portions of the flower forming a pleasing contrast of colour. *Southern Star* (fig. 76) is an evident cross between the *Poet's Narcissus* and some other near ally of that section. The perianth in the case of this variety is white, and the corona, as regards its margin, of a vivid red colour. Both varieties received First-class Certificates at the meeting of the Royal Horticultural Society on March 23, 1897.

L'ÉCOLE NATIONALE D'HORTICULTURE DE VERSAILLES.

THE National Horticultural School of Versailles is situated in the grounds of the late "Potager du Roi Louis XIV.," which was established in 1678, by De la Quintinie, Inspector-general of the Royal Gardens, in the reign of Louis XIV. Although the grounds and conditions were not very favourable to work upon, he distinguished himself by producing a real "Chef d'œuvre" where everything could be grown to perfection. The story says that the king would have Asparagus in December, Radishes and Lettuces in March, Strawberries in April, Peaches in May, &c., and that he had them, which at that time was a very rare thing.

The glass-houses where all the fruit, vegetables, and flowers were grown, have now been replaced by better ones, but the shape of the garden, with its fine terraces and walls full of beautiful fruit trees skillfully trained, is the work of this venerable gardener, and there are still a few "Catillae" Pear trees which are supposed to have been planted by his own hands, and which bear every year a heavy crop of fine sized fruits.

Until the first days of the Third Republic, all the produce of these gardens was used to supply the tables of the sovereigns; and it may be said that M. Thiers, the first president, made use of them up to 1873, when the national Assembly at the proposition of the late M. Joigneux, senator, supported by M. Guichard, decided that these gardens and buildings should be used as the site of a superior school of horticulture where nothing should be spared to train good professional and practical gardeners.

The school was opened in October, 1874, under the directorship of the late M. Hardy, formerly superintendent of these gardens.

The announcement of the opening of the school gave great satisfaction throughout France and abroad, and although the government gave an annual grant of upwards of £4000 towards the expenses of the school, with £200 a year for scholarships, help was also sent from every part of the continent and abroad in the form of money, or in contributions of plants of all sorts.

Most of the horticultural societies and departments of France award also one or more scholarships of £40 a year to young gardeners who wish to improve themselves there. Owing to the increasing success of the school every year, the number of students is limited, the average for the last three years being from 100 to 110 altogether.

The students to be admitted have to pass an examination in elementary subjects and gardening, the first six on the list receiving a scholarship from the Government of £40, unless they already hold one given by a society or province. Those who hold no scholarship of any sort, but are supported by patrons or can afford it themselves, can enter the school, provided that they have given satisfaction at the examination; anyone may be admitted between sixteen and twenty-six years of age. The studies

skilful head gardeners. There are—1st, fruit trees; 2nd, fruit trees under glass, and forcing-houses where are grown Grapes, Peaches, Strawberries, Figs, Melons, Pine-apples, &c.; 3rd, hothouses and propagating-houses; 4th, outdoor and soft-wooded plants—a botanic garden, where all sorts of medical and economic plants are grown and carefully labelled; 5th, the kitchen garden, where are grown vegetables, forced and outdoor. Besides these, there is another place where students assist in making frames, lights, and learning how to repair certain articles, such as water-cans and tools, under a superintendent. At the end of every fortnight each student has to report upon his work. In the summer there are frequent excursions made to the chief nurseries or principal places, where the students see the best ways of cultivating various plants; and they also attend

may say that some of the most important positions in France and in the colonies, are filled by ex-students of Versailles, not to mention those abroad. From Hungary, Roumania, Spain, Portugal, and Germaoy, every year a good many persons come for the same purpose as do the others, to improve themselves at the school; and English, Belgians, Turks, Russians, Japanese, Swiss, Italians, Spaniards, and others, are found among the students; and they return benefited by the experience gained in the National Horticultural School of France.

In conclusion, I may mention that there is an association formed by the students, which publishes yearly a bulletin which mentions the position of the members, and includes articles on various subjects of interest, and on the experiments made at the school during the year. *Jules Gachelin, ex-Student.*

FIG. 74.—NARCISSUS ELLEN WILLMOTT.
(SEE P. 222.)

FIG. 75.—NARCISSUS SOUTHERN STAR.
(SEE P. 222.)

extend over three years, and are divided into two sections, theoretical and practical.

The lectures are on French, grammar, mathematics, geometry, book-keeping, surveying, physics, meteorology, and chemistry applied to horticulture and agriculture; zoology, entomology, and botany (first year, classification of plants, description of flowers, &c.; second year, anatomy of plants, flowers, descriptions of diseases, &c., cultivation of fruits under glass and out-of-doors, vegetables under glass and out, flowering plants in and out, and ornamental trees), freehand and landscape drawing, and water-colours. Different rooms are used for these lectures, which are given by professors appointed by the government. Various collections of insects, animals, flowers, and fruits are open to the students; as well as laboratories in which to experiment in physics, chemistry, botany, &c. There is also a field for experiments.

The practical section includes five departments; the student has to remain a fortnight in each under

the Horticultural Conferences, which are given occasionally, and the shows.

There are two examinations every year; one at Easter to show the student what tasks he has to work at, and one in July to class them for the year; besides these, the professors question the students at intervals throughout the year. Each student has to obtain a certain number of marks to be able to pass through the second year's course; those who do not attain them are declared unable to continue their studies, and leave the school. At the end of the three years they pass a general examination in every branch, theoretical as well as practical, and if they give satisfaction, a certificate is awarded them, and the two first obtain a scholarship from the Government, enabling them to pursue their studies abroad.

Every year the director receives from all parts of the Continent and abroad applications for men to serve as directors of botanic gardens, town gardens, head-gardeners, superintendents of colonial gardens, professors in schools and horticultural societies; and I

HOME CORRESPONDENCE.

THE PROPOSED ROBERT HOGG MEDAL.—The suggestion made in last issue by Mr. Harrison Weir that a special medal for fruit should be founded to keep alive the memory of our most distinguished pomologist, will be received with extreme pleasure by all those who knew the late Dr. R. Hogg, and by those who have benefited by his work. The *Fruit Manual* is a lasting memorial of his careful skill and industry, and is of inestimable value to all fruit-growers; it is right, therefore, that the man who rendered such eminent services to his countrymen should live in their memories, and a medal seems to be the best method of ensuring this end. For many years I enjoyed the privilege of his friendship, and those years will be never forgotten by me. I shall hope to add my name to subscribers of the memorial in honour of my old friend. *T. Francis Rivers.*

... The admirable proposal made by Mr. Harrison Weir in last week's *Chron.*, will undoubtedly

receive general support, as the name of a man who has done so much for pomology could not be perpetuated in a more fitting manner. If the scheme is carried out, as I sincerely hope it will be, let the medal be expressly for the encouragement of fruit culture, and let those entrusted with the award have as wide a scope as possible. The present writer was long familiar with Dr. Hogg's wishes and thoughts on such matters, and he has many times expressed himself in favour of increasing the educational advantages of exhibitions. Mere competition for prizes he did not consider the best means of advancing the interests of horticulture. He was emphatic on this point, and he had considerable experience in the matter, for he offered valuable prizes for some years, at the time when the editor of the *Gardener's Chronicle* was also offering similar prizes—in fact, I believe they were friendly rivals. I shall be pleased to contribute to the proposed Medal fund, and the moderate sum that will be required will be easily obtained. *One of Dr. Hogg's Pupils.*

SYNANTHUS IN DENDROBIUM BRYMERIANUM.—I send you a double flower of *D. Brymerianum* which has appeared upon a strong plant of twenty pseudo-bulbs, that has flowered in three previous years, but without anything abnormal being observed. Dr. Masters' *Vegetable Teratology*, 1869, does not mention this species as subject to this deformity. The species first came from Burma four years after that date. But that work may be cited to show that Orchids as a class appear to be more susceptible of deviation from the type than are the members of most other natural orders. In the present case the flower-stalk is singularly fasciated, with a deep central channel. The structure of the floral tube would show three sepals, two petals, labellum, column and inferior ovary. In the present case, we have five sepals, of which four occupy the usual position, the fifth being rather narrow and pendent behind the labellum; and there are three petals, two labella, side by side, and each perfect; two columns side by side. I presume that the plant must not be expected to develop the same deviation from the type in future periods of flowering. My personal basis for this opinion is chiefly observation of a plant of *Richardia aethiopia*, which last year threw a double spathe, but the flower this year is normal. *R. Reynolds.*

THE SPRING OF 1897.—During the twenty-five years I have been a gardener, I never remember such a March as that we have just passed through. There has been no east wind, no night frost worth mentioning, no dust, very little sunshine, and an extraordinary amount of rain. The effect on herbaceous vegetation generally, and spring-flowering bulbs in particular, has been marvellous, and I never saw the spring garden so early or so luxuriant as it is now. Notwithstanding the rough westerly gales which we have had for nearly a week, *Narcissi*, *Fritillarias*, *Erythranthus*, *Puschkinias*, *Muscari*, *Anemones*, and many other plants are from ten to twenty days in advance of their usual flowering time, and finer than I ever saw them. *Kniphofias*, *Erenuri*, and other plants which we have accustomed ourselves to think like a dry climate, have passed through a very wet autumn and winter with little or no injury, and if we do not have a bad April, which I am very much afraid of, it ought to be something like a record season for outdoor plants generally. These remarks apply to a dry, hungry, limestone-soil in a very cold backward district, and may not be equally applicable to more favoured soils and situations; but Mr. Engleheart, who grows *Narcissi* with greater skill and success than any other English amateur on a chalk-soil in Wiltshire, has also found the season extraordinarily favourable, and has got, as I have, March and April flowers all at once. It is very remarkable how much many of Mr. Whitall's bulbs from Asia Minor improve under cultivation in a climate so unlike that of their native country; and though the earliest flowering times, such as *Snowdrops* and *Xiphodons*, do not seem to have enjoyed the excessive wet of last autumn, I am convinced that on a well-drained soil much rain is better for the garden than the droughts we have suffered from in so many recent seasons. *H. T. Elwes, Coleborne, Gloucestershire.*

GARDENING ON THE THAMES EMBAKMENT.—A charming piece of garden meets the eye of the visitor who, issuing from the Charing-Cross station of the District Railway, enters upon the piece of garden lying below the Adelphi Terrace, backed at one point by Inigo Jones' Water-gate, and at the other end by the palatial Hotel Cecil and that of the Savoy. It is beautifully kept, and just now the beds of *Hyacinths* are delightful. In the

centre is a star-shaped bed of white, pink, and blue *Hyacinths*, now at their best; the body of the stars is a large disc of white *Hyacinths*, and the six rays are formed of pink and blue *Hyacinths* alternately, and there are beds and borders of mixed *Hyacinths*, one of the pretty turquoise-blue *Myosotis disitiflora*, &c. Several beds of *Polyanthus* and alpine *Auriculas* have been netted over, so destructive to the flowers are the birds. It seems but a few years ago that the river lapped Inigo Jones' famous gate; and where this pleasant garden now stands there was an expanse of the river and the steam-barge pier. The superintendent of this garden deserves great praise for the prim neatness everywhere observable. *R. D.*

TULIPA KAUFMANNIANA.—Having read with interest of the above Tulip being exhibited at the Royal Horticultural on March 23, I should like to make a few remarks regarding its merits. I purchased four bulbs last autumn from Mr. M. Pichard of Christchurch, and planted them in a south border, with a view that they should have opened in February 26, and lasted till March 21, attaining the dimensions of 7½ inches from tip to tip of segments; the colours of the flower are yellow from the base to about half-way up, and creamy-white the remainder; shaded-rose on the outside. The remaining three flowers opened about a week later, and these are still in good condition to-day, March 29. *J. Storr, The Close, Salisbury.*

VOLES AND MICE.—In a recent issue the above-mentioned rodents are confused by classing them as "field mice or voles." I am not quite sure at present which is which, but I believe I am correct in stating that the vole does not climb, and that the field-mouse does; hence it must have been the latter Mr. Dunn saw devouring the points of Scots Firs 4 feet high, and not the vole. Voles eat round the base of tree-stems as rabbits do, and have accounted to a plague in woods, both in England and Scotland, in times past. I was a boy at Drumlanrig many years ago, when drains were dug in the plantations that the voles might fall into them, and being unable to climb out, die, or be caught, so destructive were they; and I believe the same thing has been done in the New Forest. Here we have been much bothered by both species in the gardens. After one severe winter, whole masses of a fine Holly-hedge died through the ravages of the field-mouse, which barked the stems 6 feet up completely. The vole is dumpy, flat-headed, reddish brown in colour, and short tailed. The field-mouse is a true mouse, with a long tail, a lighter colour, and a different shaped nose. We are constantly trapping both rodents here on the same ground. What purpose the vole serves in nature I do not know, but I notice that the large tracts of the common bracken have been accidental burnt here (the Wharfedale-wood) from sparks from the railway, and the torii laid bare, that the ground is one perfect network of vole-runs. Yet I have planted hundreds of thousands of Scots and Corsican Firs on this ground without harm from the voles in any way. *J. Simpson, Wortley.*

PEAR-BUD TRANSFERENCE.—Whilst the paper recently read by the Rev. Mr. Salmon at the Drill Hall on this subject was materially marred by the free use made in it of the term "crossing," as applied to budding, no crosses really being effected, yet it was full of interest in its later portion, which, in dealing with practical work, was, of course, the most valuable. But if such remarkable results can be obtained from the frequent inter-buddings of variety on variety, as the lecturer indicated, how is it that we cannot have similar demonstrations of such results nearer home? If there be any place in the world in which frequent inter-budding to see what results to which Pears may follow could be practised, surely that place is the Royal Horticultural Society's gardens at Chiswick. But I do not therefore assume that the superintendent should be required to undertake experiments of this nature, as his hands are already full. Could not a small committee of say three experts be appointed to conduct these budding experiments, certain trees, both on wall and in the open, being placed at their disposal for the purpose? If we are to credit all that Mr. Salmon told us, there is a good deal that represents gain to Pear culture to be learned from such experiments, not only in creating greater fertility, but also in obtaining higher flavour. Of course, with long unbiassed experience, we who are cold-blooded practical people, take all that is told with a large grain of salt; but all the same, it is not quite the proper thing that we should have to go to Yorkshire for practical information. To my suggestion that the rev. lecturer should send up samples of his fruit

in the autumn for which he claimed great improvement through inter-budding, no response was made. That seems to present additional reason why such experiments should be conducted under undoubted authority. *A. D.*

EUPHORBIA JACQUINIÆFLORA.—Mr. D. T. Fish remarks, at p. 207, that he has never seen this plant stopped, pruned or trained into good specimens. The largest specimen that I have seen was in a Cheshire garden, of which the writer's brother had charge. This plant was about 5 to 10 feet across the fan, and about 3 feet high from ground. It was planted in lumps of fibrous peat, loam, and brickrubble against a partition 'twixt a store and intermediate-house, and was wreathed with its inimitable sprays of blossoms—practically furnished the glass partition referred to. The plant was freely stopped, for its flowering sprays were used for decoration. It had very little root-room, and the roots being at ground-level were given no moisture for weeks together in dull weather. I have myself grown very fine plants in strong loam and burnt clay-earth in equal parts, not a particle of peat or sand being employed. These were planted out on a raised bed in a house devoted to *Gardenias*, *Eucharis*, and *Adiantum Ferns*, and were intended merely for stock when originally planted. There were about eight planted from 5 inch pots, bought in the autumn at a London sale, and sent northwards. From these I rooted 500 plants one spring, which kept the shoots in check. During the summer following, however, growth became abundantly free, and little attention was requisite. Had Mr. Fish seen these or the fan-trained example I have referred to, he would not have said the cultivator "gains nothing by stopping his plants," or that he "sacrifices vital force." The plant is too frequently killed by excessive watering, which means destruction to the delicate fine roots. It is frequently planted in inferior peat, that retains water as a sponge would do. If gardeners would plant this *Euphorbia* in sound loam and burnt clay earth, and afford ample drainage, at the same time avoiding manures of all kinds, and always keep it moderately dry, there would be fewer failures. The fan-trained example referred to above was grown in a pot for nearly a year, and took about one year and a half to cover the space named. At five years old it was the finest plant of its kind I have seen. *J.*

DESTRUCTION OF ANTS IN HOUSES.—I observed in a recent *Gardener's Chronicle* an answer to an enquiry by "Artus" as to the best means of getting rid of ants in glass structures. No doubt if the nests and haunts of the ants could be easily got at, a solution of carbolic acid would kill or shift many; but it is often difficult to get at the nests or haunts, and if disturbed in one place, if not killed, they simply move to another just as mice do in the same or an adjoining house. Treacle and other sweet compounds mixed with arsenic may thin their numbers for a time, but they soon stop taking it, and the relief is only temporary, as so long as the queen ants keep on depositing eggs, so long will the supply of ants be kept up. I have tried most of the so-called remedies with very indifferent success. So, a few years ago I tried, with better results, "Smith's Ballinquinrain Ant-Destroyer," which Mr. Smith claims to be a slow poison, and capable of being carried to the nest by feeding the queen and young. For a few months, with perseverance, we had the satisfaction of seeing the ants gradually disappearing, and before a year was out, there was scarcely one to be seen about the place under glass. For some time now we have been almost entirely clear of ants. In spring a few pot in an appearance, probably from outside, but they are easily disposed of. I observe by the label that Mr. Smith says the Ant-Destroyer exterminates cock-roaches and beetles as well. If so, it should be a boon to many gardeners, and should be better known. *D. McNeill, Inverurie Castle Gardens.*

DENDROBIUM NOBILE VAR. COOKSONI.—We have at present a *Dendrobium Cooksoni* in bloom having forty-nine flowers, the lovely dark colouring of the lip extending over three-quarters of the area of the petals, giving the flowers a very charming appearance. I would ask readers of the *Gardener's Chronicle* if such fine specimens of this species are common? To my mind it is a great improvement on the ordinary noble. *R. J.*

BULB MITE.—I was much interested in Mr. Nield's article in last week's *Gardener's Chronicle*, respecting his experience with the bulb-mite, in *Eucharis* particularly, because my experience has

been entirely opposite to his. Mr. Nield's plants became unhealthily in a high temperature and plenty of light, and on being placed in a lower temperature and heavily shaded, immediately recover. While my plants which had been in an intermediate temperature, and during the summer months heavily shaded, became very unhealthy, and nearly all the leaves gradually yellowed off; but on being placed in a brisk bottom-bath, high top-temperature, and moist air, they soon began to recover, and are now good, healthy plants, throwing up plenty of strong flower-spikes. Of course, I shaded them from strong sunlight, but the reverse conditions, which has proved beneficial to Eucharis, would make it evident that the old proverb, "What is sauce for the goose, is sauce for the gander," is scarcely applicable in their case. *Frederic Tugwood.*

AN EARLY BIRD.—A young thrush which had left its nest was caught in these gardens this morning (March 31). It was quite strong on the wing. *R. Edwards, Dechy Lees-Offord, Sevenoaks.*

THE COLOUR OF TURNIP FLOWERS.—Why should the flowers of white Turnips be a deeper shade of yellow than those of Golden Ball Turnips? I first noticed this was the case when driving slowly one fine day alongside a field of Golden Ball Turnips in full flower. Among the mass of pale yellow flowers I observed one or two which were of a slightly deeper shade of colour. On pointing this out to a friend who was with me in the trap, he proposed an examination, which we soon carried out, and found that the few deeper-coloured flowers belonged to white Turnips, which, of course, ought not to have been there, and which were forthwith pulled out and unceremoniously huddled into the ditch at the roadside. *William Cuthbertson.*

SCOTLAND.

EDINBURGH BOTANIC GARDENS.

EARLY-FLOWERING HARDY RHODODENDRONS.—Recently the plants of *Rhododendron darwinii* were at their best, the rosy-purple blooms, very numerous produced, having a nice effect; when grouped in a bed, as here, the plants gain in attractiveness. The variety *atro-virens* is also in close proximity, affording a good contrast. Under fair treatment, these shrubs may be depended upon to make good growth and flower freely annually. *R. precox*, the hybrid of which the above species is one of the parents, has flowers individually larger, and of a slightly lighter colour. Taken into a greenhouse, and gradually forced, all of them will flower some time before outside plants, and are then useful for the decoration of the conservatory. These early-flowering species and varieties are liable to damage by late frosts, but apart from this the blooming period lasts for some weeks. *R. nobleanum* is, of course, in evidence, the heads of rose-coloured flowers being conspicuous among the dense foliage. *R. L. H.*

NURSERY NOTES.

MESSRS. BARR AND SONS.

TUESDAY last was a glorious day to visit a hardy plant nursery, for the cold winds had subsided and the bright warm sun was continuous. Everything out-of-doors was cheery, and it was one of the few days that have occurred this spring when one could walk over miles of nursery paths without discomfort.

March never passes before the Daffodils have commenced to afford a display of blooms in Messrs. Barr's nursery at Long Ditton, near Surbiton, but it is not often that so many blooms are developed so early as they are this season. We were somewhat surprised, indeed, to find that the mid-season kinds had yielded most of their flowers, and the bright show annually to be seen there was swiftly passing. Many of our readers probably know by name and experience the best varieties of Narcissi. We shall content ourselves by mentioning a few of the best that were carrying an abundance of flowers on the date already mentioned.

To commence with the Yellow Trumpet varieties: it goes without saying that the old and excellent Emperor was prominent among them, for it is cultivated in very large breadths. Resembling Emperor is one named P. R. Barr; it is said to be a good grower, and has a refined flower, but it certainly does not surpass the better known one. M. J. Berkeley, rich golden-yellow with a fine expanded trumpet, and reflexed brim, is a capital member of this section; and Monarch is a new trumpet of 1895, and therefore a very expensive one at present—it is of good form, full, rich yellow, large, and is said to be a good grower. Golden Spar, and several other excellent trumpet varieties were noticed; and Glory of Leiden (figured in the *Gardeners' Chronicle*, April 18, 1896). The last-named is one of the largest of the giant trumpets. The little cyclamenus major must be mentioned, for although it is very well known, it is not seen so frequently upon rockwork and other suitable positions as it might be. This elegant miniature Daffodil has bloomed exceedingly well at Long Ditton, but when this note is published, most of the flowers will have passed. The trumpet varieties with white wings, embrace many excellent flowers, including the ever-popular Empress. But one of the best of these is J. B. M. Camm, which has an exceptionally refined form and delicate colour. Wearable Perfection is not only the largest bi-coloured trumpet, but the boldest of all Daffodils. Grandis, Horsfieldi, and Madame Plémp, are also good ones. The last-named has broad perianth segments, and a fine long rich trumpet.

There are several very pretty Trumpet Daffodil, with white or pale-coloured flowers. We noticed of these, Matson Vincent, Marchioness of Lorne, moschatus, Snowflake, tortuosus, and William Golding. The last-named is of drooping habit, has pale primrose trumpet and white segments, and is sometimes called "Swan-neck Daffodil." Tortuosus resembles Snowflake in a measure, but is scarcely so good. Cernuus, Madame de Graaf, and Mrs. J. B. M. Camm, may be mentioned in addition to the above.

The Incomparabilis group, or "Star" Narcissus, is perhaps more popular than any, and there are innumerable varieties. Take the Barri strain, it includes Sensation, Siddington, Maurice Vilhorin, Flora Wilson, and Conspectus, all of which were to be seen in Power at Ditton. Siddington, however, is later than most of the others, and but few blooms were open. Conspectus is the best-known and most desirable of them; it is one of the prettiest and most useful of all Daffodils. There would be a magnificent show of it a few days after these notes were taken.

Then there is the group of which Sir Watkin and Gloria Mundi are well-known types; we noticed Gwyther, King of the Netherlands, Autocrat, Lutworth, and Beauty.

Of the Leedsi section, there were in bloom Duchess of Westminster, Katherine Spurrell, and Mrs. Langtry. Each of these is good, but the last-named is rather later in blooming than some of the others. Nelsoni arantius is a pretty flower, having a goblet-shaped cup of considerable attraction, and a broad white perianth. Of the varieties of *N. odoris*, Heminalis is the best; it is rich golden-yellow, has a long cup, and is much more fragrant than rugulosus.

But few of the Burbidgei varieties were yet in bloom, and these and the Poet Narcissus will make a display for some weeks yet. We should mention the rush-leaved Daffodil, *N. juncifolius*; it is a very dwarf species, with tiny rich yellow fragrant flowers. We had the pleasure of inspecting a number of promising seedling varieties of Narcissus, but, as they are at present without names, and of course not to be obtained by the trade, we need not at present describe them. For several years past, Messrs. Barr have found it advantageous to protect the Narcissus beds during winter with leather. This is laid over them before severe weather sets in, and is removed as soon as the plants are seen pushing through the ground.

Though at present Daffodils are the chief attraction at these nurseries, they are not the only one, for there

are beds of Tulips which made a wonderful display of bright colour, including such varieties as Vermilion Brilliant, Vesuvius, Canary Bird, White Hawk, Chrysolora, Pottbakkher in variety, and Keizerskroon.

Among several species of Tulipa, *T. bitoria* major looked very pretty; it has small distinct flowers with yellow base, the rest of the flower white or palest-lemon. A very decisive patch of blue was afforded by some beds of Muscari conicum; it formed a distinct feature in the nursery. In smaller quantities there were other Muscari, including *M. paradoxa*, *M. cornubum*, and *M. Gussoni*, all of them pretty. *M. paradoxa* has large pyramidal-shaped inflorescences, that go almost black in colour. Upon and near the rockery the Alpine plants are commencing to grow, but beyond a few Primulas, including *P. nivalis*, pure white, there are few of them in bloom yet.

Altogether, the nurseries at Long Ditton are very interesting at this season of the year, especially to those who admire Daffodils—and who does not!

MESSRS. J. VETCH & SONS (LIMITED).

At this well-known nursery Hippeastrums (*Amaryllis*) form an important feature at the present time, and will continue to do so for some five or six weeks longer. Great advances on what has hitherto resulted from the labours of the cross-breeder are not forthcoming, nor, indeed, expected; but improvements in form, and the elimination of the supposed objectionable green colour in the basal portion of the segments of the flowers, are being persistently followed up.

In pleasing symmetry of the flower, and in colouring, we have little that is new to chronicle; all shades of crimson, red, scarlet, and even purplish-crimson and cherry red, and their various combinations with white and creamy-white, were remarked. In previous years the visitor has had to lament the brevity of the display, but by ripening off the bulbs at various times during the summer and early autumn, the time of flowering is varied, and consequently, the season of flowering of a large collection is lengthened, as it were, at both ends, although the bulbs are started into growth simultaneously, and their treatment is identical. In looking through the beds, there were bulbs with blooms on the wane, others in full beauty, some with scapes just pushing up from the bulbs, and in various intermediate stages; still, the display of open blooms seemed to be as large as usual.

Of fine novelties of good form of the present year, mention may be made of *Thelma*, a crimson-coloured self; *Foini*, white rays on a cherry-red ground; *Chio*, crimson, with distinct reticulations on the flower; *Charmion*, faint red stripes on a white ground; *Chigo*, an unusually brilliant scarlet flower, with a white band in the middle of each segment; *Cnyd*, cherry-red streaks and flakes on a white ground; *Xantho*, deep crimson, and segments rather pointed; *Francisca*, a broadly-expanded bloom, bright crimson; *Hilalago*, crimson, all but a patch of green colour at the base, the largest flower seen in the collection. *Ora*, *Corisande*, *Gem*, *Abra*, *Fulpendon*, *Carnis*, *Phrynia*, and numerous others with fancy names were noted.

The seedling *Cleives* now in bloom form a beautiful display, most of them being equal to anything to be seen elsewhere under name, corymbs large and many-flowered.

A large span-roofed house, devoted to most seasons to displaying plants in flower, was gay with Dutch bulbs grown at their best, dwarf little plants of *filix*, *Hydrangeas*, *Viburnum Opulus*, *Acaia Drummondii*, the exceedingly pretty *A. cordata*, the numerous drooping shoots thickly clothed with creamy-white blossoms; *Azalea mollis*, *A. indica*, the floriferous *Azalea obtusa* alba, and *A. o. calyciflora*; the deliciously-fragrant *Boronia megastigma* in two varieties, *Erica Cavendishi*, *Magnonette*, &c.

A passing glimpse of the Orchid houses enable us to speak of some of the firm's achievements in hybridising Orchids, of these are *Bendrobium Anceipe*, the parents of which are inappropriately, as regards their names, *D. Wardianum* and *D. Free-*

mani—the blossoms are white, purple tipped; *D. nobile robustum*, certificated in 1896; *D. Ainsworthianum* intercompact, flowers chiefly white, the base of the lip only being purple coloured; *D. sulphureum* is of *D. nobile* and *D. aureum* parents; *D. Edithæ* belongs to the *D. nobile* section; *D. Azeas*, a cross between *D. crystallinum* and *D. japonicum*, has fragrant blossoms, white, with a faint lilac-coloured edge and lip; *D. Wiganie* has creamy-white blossoms, with a lip that has a purplish blotch at the base.

The rock Orchid-house had numerous plants in bloom, and the other rock-house was gay and charming with *Tillandsia Lindenii*, *Criminum macrostaphanum*, *Cactus Gaertneri*, and *C. Makoyana*, *Talernemontana coronaria*, *Begonia Gloire de Sceaux*, *Cliviae*, &c. The trailing *Pothos*, and other plants, used to clothe the rocks, have the tender tufts that come with the renewal of growth.

SOCIETIES.

LINNEAN.

MARCH 13.—Dr. A. GUTHRIE, F.R.S., President, in the Chair.

The Right Hon. Sir JOHN LUNBOK, Bart., M.P., read a paper on "Stipules, their forms and functions." This eulogistic observations supplementary to those published in previous papers (*Lin. Soc. Journ.*, Bot. xviii. 217, and xxx. 463). It was shown that while the usual function of stipules is to protect leaves in bud, in some cases they replace them, and in others serve to hold water. Instances were mentioned in which stipules developed into stipes, and in other cases became glandular. Where stipules were absent, other arrangements for bud protection were found to exist. Attention was especially directed to the formation of the winter buds of certain common shrubs and trees, and some curious differences were noted even in nearly allied species. In the Waxwing tree, *Viburnum Lantana*, the author remarked that the young leaves are uncovered, but are protected by a growth of hairs; in the Ash and Thorn the outer scales of the bud consist of expanded petioles; in the Willow the outer scales consist of leaves; in the Poplar of stipules. The buds of the Oak and Beech were also described, and it was shown by the aid of lantern-slides that in the Beech the outer scales of the bud consist of two pairs of stipules, that the twelfth pair are the first which have a leaf, and that the subsequent growth is between the leaves, while the portion of the shoot between the stipules scarcely elongates at all. As a consequence the seat of each winter bud is marked by a ring, and thus a series of successive rings, which remain visible for many years, indicate each year's growth.

A discussion followed, in which Mr. A. W. BENNETT, Prof. Farmer, and Mr. A. B. HENDLE took part.

Mr. W. C. WOODRILL read a paper "On the Origin of Transfusion-tissue in Leaves of Gymnosperms Plants." It was explained that "transfusion-tissue" is a special kind of conducting-tissue found chiefly in the leaves of Conifers, in direct connection with the vascular bundles. "Centripetal" xylem, only known to occur in the leaves of Cycads among living plants, has been found well developed in the cotyledonary bundles of *Ginkgo biloba*. In these latter, and in the cotyledonary bundles of *Cycas revoluta*, a distinct transition was observed between the elements of the centripetal xylem and those of the transfusion tissue at the side of the bundle.

In studying the structure of the vascular bundle in the leaves of Conifers generally, a similar transition was also observed in a few genera between centripetal xylem and transfusion-tissue. These facts lead to the conclusion that transfusion-tissue, as universally found in recent Coniferous leaves, has originally sprung from the centripetal xylem of the leaf bundle in Leaves of Gymnosperms Plants.

In the discussion which followed, critical remarks were made by Dr. D. H. SCOTT, Professor Farmer, and Mr. G. R. MURRAY.

The objects exhibited included various forms of Cyclenæ and Cinerarias, by Mr. T. THURSTON-DYER; and drawings by Mr. E. B. GREEN and photographs of plants with various parasitic growths, by Mr. ALBERT W. BERRY.

The next meeting of the Society will be held on Thursday, April 1, at 8.0 P.M. precisely, when the following papers will be read:—Dr. A. J. EWART, B.Sc., on the "Evolution of Oxygen from Coloured Bacteria." MISS HELEN B. POTTER, on the "Germination of Spores of Agarieines." (Communicated by Mr. George Massee, F.L.S.)

TORQUAY DISTRICT GARDENERS.

MARCH 24.—The Second Annual Spring Show was a considerable success. The large hall at the Bath Saloons was lighted by electricity by special arrangement, and the effect in the evening was very charming.

Messrs. H. YERVIS & SON of Exeter showed some very attractive rock-plants and Cutis, together with a collection of

Narcissus blooms. MESSRS. CUTTS, SANFORD & CO., LTD., were well represented by a stand of flowering and foliage-plants, including some fine Anemylis. The SOUTH DEVON FRUIT FARM (manager, Mr. T. PENDER) had large Strawberries and many other collection of vegetables. MESSRS. ALWAY, BRACEY & CO., HORS & SON, and W. BRIDGER & SONS, also exhibited, the last-mentioned firm contributing some fine tall Palms, which formed a grand centre-group in the show. Mr. J. SNEEGROVE of St. Elms (gr., Mr. W. Bile) showed an attractive stand of well-grown plants, including many Orchids. Miss LAYTON (gr., Mr. G. Lee) exhibited a group of Orchids. The TORQUAY TOWNS COUNCIL were fittingly represented by an exhibit from the public gardens of the town, and consisting of miniature beds filled with Hyacinths and Tulips, with a background of imitation rockery and sub-tropical plants.

Mr. W. J. GIBBERT of Ennouth had some good new zonal Pelargoniums; and the JAMES FERRIS CO. showed an attractive stand of plants grown in the fibre. The principal prize-winners were Mr. J. W. KIMBER (gr., F. C. FERRIS), Dr. W. FORD EISELOW (gr., C. R. PROWSE), who was 1st in the miscellaneous groups; Mr. P. W. HUSHEY (gr., F. PENCOCK) who was 1st in the table-composition; and very highly arranged exhibit; Miss LAYTON (gr., G. Lee), and Capt. W. FASE TUCKER (gr., J. Sloan), who had some very well-grown Narcissi and Hyacinths.

Mr. W. B. SMALE was represented by a showy stand of Palms, Cinerarias, and Azaleas, together with a table of the best varieties of Cinerarias. The medals and certificates to be awarded at the autumn show were also on exhibition.

The building was crowded during the afternoon and evening, and the attendance included Prince Albert of Belgium, who is at present staying at Torquay.

BIRMINGHAM GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.

The Hardy Bulb Culture in England.

[By F. W. BRIDGER, M.A. Read before the Birmingham Gardeners' Mutual Improvement Association, March 15, 1897.]

(Continued from p. 211.)

THERE are in England to-day thousands of acres of waste land suited for bulb culture. All around our sea coasts, especially there are sheltered sunny nooks and valleys that are unweeded by wind and unscathed by biting frosts, even during our usual winter season. These places require selection and cultivation; in a word, we must discover our own land. You do not want the expensive horse-power, the deep tith, and the heavy manurings necessary for Swedes or Mangolds in order to grow bulbs successfully, but you must have a loam sufficiently sandy to be workable even during a rainy season.

The best bulb-soils are deep, rich tracts of alluvium or "Trent War," beside rivers, or in valleys near the sea. In Lincolnshire there are deep sandy soils, not unlike those of Holland, on which most bulbs thrive well. Near Caistor were fine flowers and bulbs in growth, and so also in the neighbourhood of Boston and Wainfleet.

Messrs. Pearson & Sons, of Chilwell, Notts, have been very successful in growing Narcissi, as also many market growers in the Thames Valley, and especially Mr. James Walker, formerly of Whifton, and now of Ham Common, Middlesex, who has been successful in growing and making a speciality of Narcissus culture for the London markets.

In planting stock bulbs do not plant too deeply. It true that the finest flowers are those produced by bulbs deeply planted, especially on light, warm, and sandy soils, but such flowers are produced later, and the bulb increase is much less than when shallow planting is the rule. A depth of 3 to 4 inches is ample on ordinary soils.

It is most important to replant stock bulbs as early as possible, and to perform that operation during dry weather. Plant dry and on a firm bottom. All stock should be planted at latest before August if the best of results are desired.

Sloping land or banks amongst sheltering rocks, totally inaccessible to horse or plough, may often be made profitable by the scale and bulb culture. I have seen the wind and spray-swept Scilly Islands, and the thrifty flower plots along the rocks of Bournemouth, and this along with English shores there are sheltered and well-watered spots now lying waste, where many things, if not everything, would be possible to the intelligent bulb-grower.

It is almost incredible, but it is true, that 100,000 Hyacinths or Narcissus may be grown on an acre of land in England. It may be done, not by growing on in same area; and when we come to such small fry as Crocus, Snowdrops, Squills, Anemones, Winter Aconites, &c., the numbers run up to 200,000 and 300,000 per acre.

Bulb culture often means a double profit, because, if produced early, the flowers may be a valuable crop, and a remunerative bulb harvest still remains. The best results will be obtained by utilising light and airy greenhouses in which to

forward or develop the earliest flowers, and in such structures in the sheltered, sunny nooks by the sea, before mentioned as most suitable, but little fire-heat will be necessary. These greenhouses are of course available for Tomatoes, or other cultures after the bulbs are overgrown.

I shall not go into the price of the per 1000 in order to show you how very profitable bulb-growing must be on all suitable soils, when undertaken by people who understand the subject. There are several factors that must occur in bulb culture, as in all other ways of making a living off the land.

First, the land must be that naturally most suitable to the kinds of bulbs grown, and naturally or artificially well sheltered. Secondly, the cultivator must not only know how to grow his bulbs well, but how to put them on to the best markets, and, thirdly, only the best kinds or varieties popular in the market must be largely grown.

In special cases a combined course of culture is better than a simple one. That is to say, fruit trees and bulbs may both occupy the same acreage with advantage, or, bush fruits and choice vegetables may also be grown side by side with the bulbs. But, on soils especially suitable in sheltered aspects, no culture I know is more surely remunerative than bulb culture. Nothing but a new roadway, or the most liberal of building contractors, can induce the successful bulb-grower to move on and vacate his holding.

To new beginners the selection of the land is a complex problem. As the experienced grower says, "Knot and then an accidental clump of bulbs, or a fruit tree tells the tale. A practical bulb-grower has a seventh sense, and knows, as it were, by instinct when he sees a suitable bulb-land. But, if at all possible, an actual trial of bulbs of all kinds should be made, when they will soon give evidence of the best, as to the suitability of the soil and the land. As Arthur Young long ago said, no ground is too high for the best land, and none too low for the poorest of soils; an land that will grow bulbs and fruit to perfection is often to be had at a reasonable rate, especially now that grain crops are not so profitable as of yore.

An acre or two of good bulb land will pay better than ten acres of ordinary farm or garden produce, and I should not like to say the value of a root even of such select *Daffodils* as Madame de Graaf, Golden Bell, or Glory of Leyden—to say nothing of choice sorts that are rare, such as Monarch, Weaville Perfection, Hobcock's Pride, or the Big and beautiful, the Ben Willmore. The Hon. W. Lubbock, the late Mr. G. H. Engleheart's seedlings, not alone of *Daffodils* proper, but of other sections such as *Peelers* or *Incomparables*, like *White Queen*, or the new and much improved seedling *N. poetice*.

My very hardy bulbs that are never more than 40 per 1000 in the market will pay to grow it. Second and heavy bulbs—clean-skinned as possible, find a ready sale, even though not quite so perfect in form and in coat or skin as those from abroad. I have had bulbs of this class by the thousand from Scilly and the Isle of Wight sent, tied tightly in sacks, like Potatoes, and they flowered as well or better than the finest Dutch roots packed in barrels and chests and sent to England. The rough exterior of a bulb is not always an indication of its flowering qualities. A smooth-skinned and shapely bulb looks better in the store or shop, but it does not always behave better in the garden!

All large, sound, and heavy bulbs, even if rough coated, should be trusted to bloom well. As to the comparative merits of Continental v. English bulbs, I may say that, while I believe our friends in Holland can, or rather do, produce the best Hyacinths, and, perhaps, also some early Tulips, yet we in England and Ireland grow by far the best Narcissi, like Tulips, Snowdrops, and scents of all kinds.

So far as Narcissi are concerned, we can defy the world, both in rearing new and in growing all other varieties to the greatest perfection of luxuriant health and beauty.

It is not easy to find out how much is paid by us for imported bulbs from all sources every year, but it must be an enormous sum, and a very large proportion of it might be spent at home in the encouragement of bulb culture on English soil. I am a believer in free trade, and in all fair trade; but above all I believe in our home trade and in our home industries.

Finally, I believe that every bulb-grower should devote special care to his rearing new hybrids and seedlings, so that there may be progress ahead, as well as lateral diffusion in bulb culture.

What Leeks, Backhouse, Herbert, Horsefield, Engleheart, and De Graaf have done, may be equalled or surpassed by other cultivators. Beautiful as are the finest of our new seedlings today, they are not perfect in all ways, and there is room and a welcome for many more, equal or superior to them. It may not be so profitable to rear seedlings as it is to grow quantities of older kinds in good demand; still, given a perfect bit of Narcissus soil, I believe it would soon pay or a clever grower to take up the special culture and increase of all the rarest and most beautiful new kinds. The best varieties of bulbs to grow, of course, depend on soil and climate, &c., but all the best Narcissi, Self Tulips, Squills, Anemones (especially *A. fulgens*), Gladioli, Crocus, and Snowdrops, are profitable crops wherever they will thrive in quantity, and these may be supplemented by other and rarer kinds. F. W. Bridger.

BRUSSELS ORCHIDENNE.

MARCH 16.—Orchid-growers may remember the Odontoglossum Augustinum staged at the Temple Show last year, and that the plant was sold by M. Linden to a Belgian grower for nearly 800 francs.

At the meeting of March 14, M. LINDEN showed an even more beautiful novelty. The flower was more perfectly rounded than that of Faehn's, the spots were of a more vivacious tinge, the edges slightly cut. It really is a magnificent introduction, and has been named *O. crispum* var. *Lindiana*, after Mr. Lucien Linden.

Odontoglossum. Anti Charles and O. Kogodiani, shown at a recent meeting of the Royal Horticultural Society of London, obtained an equal success here. Another fine novelty is *O. x* Pauselsia, the divisions of the flower ivory-white, with a greenish-yellow edge, and all marked with large dark chestnut spots. The plant is named in honour of Mr. F. Fawcels. M. DE COYD & BOUTEVILLE sent a much-admired *Cypripedium Rotherhildianum*, a sturdy plant with three vigorous racemes, one with four, the two others each with three blooms. *C. Chalesworthianum*, from M. VAN WAMBERG, was remarkable for its large standard; *Oncidium Phlogopis grandiflorum superbum*, from M. LINDEN, had the dorsal sepal very finely flecked, with a pretty white border; the two petals have large and dark spots. *Cypripedium x Boutevillense* (Spiræanum x Boxalli), from the same exhibitor, is a fine hybrid. *C. Lohaniyanum superbum* surpassed all specimens seen on former occasions; the petals are very dark chocolate-brown, the standard large, and nicely marked. An artificial hybrid *Odontoglossum*, *O. cirrho* Hillii, from M. LINDEN, obtained a success, owing to the beauty of the flower. *O. Rossi majus*, from M. PAUWELS, was very fine; a small specimen of *Lycaste skomeri* bore nine large and fine flowers; *Phaiosopis Schilleriana* and *Amabilis*; *Miltonia Robt. Lobbii*; *Phaiosopis* var. *Amabilis*, from M. LINDEN. *Epidendrum Wallisi* (*odontoglossum* class), from M. O. Hilli (enclousion), from M. WAREHAM; some fine varieties of *Cypripedium* *insigne* var. *Pauli*, from M. DEAN; and many other Orchids may also be included among the chief exhibits on this occasion.

ROYAL BOTANIC.

MARCH 31.—An exhibition of spring-flowering plants took place on the above date in the gardens of the Royal Botanic Society, Regent's Park. In each of the classes there took competition; but in the case of Cyclamen there were four collections staged. The long corridor was well filled with exhibits, and a moderate overflow was staged in the large conservatory. The display was chiefly due to the trade, there being several extensive collections from the nurseries. Mr. THOS. S. WARE, Hale Farm Nurseries, Tottenham, was awarded 1st prize for a collection of hardy herbaceous plants, with a group including *Primulas*, *anemone*, *veronica*, *dianthus*, *dianthus*, *daisy*, *rose*, *fuchsia*, a slender, dwarf-growing, pink-flowering *Callitriche* Tenax var. *Ammonia*, *Malva*, *Malva*, *Cuscuta*, *anemone*, *ranunculus*, *fulgens*, and *alpinia* *oliphurea* (a very pretty variety), and various other specimens of hardy plants.

Mr. W. RUMSEY'S 11 prize exhibit of six roses in pots consisted of nice dwarf plants of *Souvenir d'un Ami*, *Melrose*, *Edouard Levot*, *Maquis* *Charta*, *Viscountess* *Folkstone*, *The Queen*, and *Catherine Sempier*.

The best twelve pots of Cyclamen were shown by The St. George's Nursery Co., Hanwell, and though some of the blooms were not so fresh looking as they might have been, the number of blossoms upon each plant was unusually large. Messrs. PESTRELLI & SONS, var. *Ammonia* *Pauli*, *Broutin*, were 2nd with plants of a very different strain, but still of much merit. There were two other exhibitors.

Mr. H. PERKINS, gr. to the Hon. W. F. D. SMITH, Greenlands, Henley, obtained 1st prize for a dozen *Hippocisternus* in bloom; and Mr. J. G. MOWBRAY, gr. to Major Hon. H. C. LEVER, 1st prize for six *Cornus* *Primulas*, showing large, but not particularly smart-looking plants.

The only exhibitors of a dozen *Giacintus* in pots were Messrs. MORLE & CO., Finchley Road, N. 1st prize was awarded, but they were not of first-rate quality.

The cup offered by Messrs. BURN & SONS for a collection of Primrose blooms was only competed for by one exhibitor, and it was awarded to R. MARLAND, Esq., Warlord Lodge, Sunningdale. The exhibit included numerous varieties of the group;—*Magn-coronata* (*Trumpet Daffodils*), *Medio-coronata* (*Cup Daffodils*), and *Parvi-coronata* *Small-crowned Daffodils*. It was a good representative collection, and the blooms were of commendable quality.

NON-COMPETITIVE EXHIBITS.

A very extensive group of plants was exhibited by Messrs. P. & W. WILLIAMS & Co., Upper Holloway, London, N. The group was composed of plants of various kinds, most of them excellent. Of the *Ciclas*, *Queen Victoria* was decidedly the best. It had a bold handsome model, bearing a great number of large buds of much substance. *Staphylea trifolia*, *Azalea mollis*, *smensis*, *Boronia* *alnica*, *Gaultheria* *Rosea*, *Hippocisternus*, *Scilla*, were very representative, though small group of Orchids were included in Messrs. WILLIAMS' exhibit.

MESSRS. JOHN LEUNG & SONS' group of miscellaneous plants from Forest Hill included excellent *Clematis*, *Sorbaria*, *Rhodula* *Paulina*, and *R. p. maculata*, *Anthriscus*, &c. A bright display of spring-flowering plants was contributed by Messrs. J. PLEW & SONS, Roupell Park Nurseries, Norfolk Road, S.E.

MESSRS. W. CUTBUSH & SONS, Highgate Nurseries, London, N., exhibited an excellent group of plants, including batches of *Campanula* *St. Botolph*, *Campanula* *St. Botolph*, *Acacia* in bloom, *Erica* *Cantabrigia*, *Wilmoriana*, and *coccinea* minor, *Boronia* *hottentotta* and *megistota*, &c.

MESSRS. Wm. PAUL & SONS, Waltham Cross, Herts., again exhibited *Camellia* in pots; and in addition, some pretty examples of *Prunus triloba*, *Forsythia suspensa*, the double-flowering *Almond*, and the double white-flowering *Exochorda*.

MESSRS. PESTRELLI & SONS, Boston Road Nurseries, Brentford, exhibited a collection of about forty-eight plants of Cyclamen; and the ST. GEORGE'S NURSERY CO., Hanwell, staged an excellent group of these plants, including a number of plants of their "grandiflora" strain, figured in the *Gardener's Chronicle* last week.

Rose-blossoms from Mr. GEO. MOUNT, Canterbury, were very pretty, a considerable number of varieties being exhibited, including some of the hybrid Scotch varieties. There were a dozen and a half bushes of *Catherine Marnet*, a pretty rose which seems to be a *speciosa* at the Canterbury Nursery.

A group of Roses in pots, and a considerable number of untraced blooms came from Messrs. W. RUMSEY & SONS. A group of *Mignonette* plants of much merit was staged by Messrs. MORLE & CO., Finchley Road, London, N. A very pretty group of miscellaneous and spring-flowering plants was exhibited by Mr. R. SLOTT, gr. to CAMPELLE NEWINGTONS, Eps., The Holme, Regent's Park.

A gorgeous display of Narcissus blooms was made by Messrs. BURN & SONS, King Street, Covent Garden. The varieties were to a large extent the same as those noticed on p. 225. Mr. T. S. WARE staged a good collection of blooms of *Narcissus* of the trumpet, incomparabilis, and other sections, including *Poa* *perca*.

MESSRS. JAC. VERON & SONS, Ltd., Chelsea, showed a small group of very fine *Primrose* blooms, the freshest and of colour of them being remarkable. *Empress*, *Empress*, *Horsfield*, *Golden Spur*, *W. Golding*, *Henry Irving*, *Madame de Graaf*, the double-flowered *Talonibus*, *Orange* *Pixidia*, many of the *Incomparabilis* group, and *Poa* *perca* *perca* were included.

MESSRS. WAREHAM & SONS also exhibited some novelties in a corner of the conservatory. We noticed several good *Giacintus* and *Hippocisternus*, also *Discolorum* *Leschenaultianum* variegatum, *Streptocarpus parviflorus*, a very pretty plant producing numerous small intense coloured flowers upon very slender inflorescences. *Polystichum* *parvifolium*, and several pretty hybrid *Epidendrum*s, and other Orchids.

THE WEATHER.

(The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees, a "Day-degree" signifying continued for one hour at four times of any other number of degrees for an inversely proportional number of hours.)

Table with columns: DISTRICTS, TEMPERATURE, RAINFALL, BRIGHT SUN. Rows include districts like London, and weather data for the week ending March 27.

Table with columns: Day, Deg., 10th Deg., 10th Inch, Ins. Rows show weather data for days 1 through 11 of the week ending March 27.

The districts indicated by number in the first column are the following:—0, Scotland. N. Principal Wheat-producing Districts—1, Scotland, N. E.; 2, England, N. E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. Principal growing, &c. Districts—6, Scotland, W. 7, England, N. W.; 8, England, S. W.; 9, Ireland, N.; 10, Ireland, S.; *Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending March 27, is furnished from the Meteorological Office:—

The weather during this period was extremely unsettled and rainy over all the northern and western parts of Scotland, and less so over the other northern and western districts, but over the eastern and southern parts of the Kingdom the condition was mostly fair and dry.

“The temperature was much above the mean, the excess varying from 5° in Scotland, N., and the Channel Islands, to 8° in England, N. E., and 9° in England, E. and the Midland Counties.” The highest of the maxima were recorded as a rule on the 27th, when they varied from 63° in England, S., and E., to 55° in Scotland, W., and 51° in Scotland, N. The lowest of the minima, which occurred generally during the earlier days of the week, ranged from 32° in Scotland, E., to 42° in England, S., and to 43° in the Channel Islands.

“The rainfall was much above the mean in the north and west of Scotland, and considerably in excess over Ireland and the east of Scotland, while in the eastern and southern districts of England there was a considerable fall.”

“The high barometer was less than the normal in all districts, except Ireland, N.,” the difference from the mean being large in all the northern and north-western parts of Great Britain. The percentage of the possible rotation ranged from 31 in the Channel Islands, and from between 29 and 23 over England and Ireland, to between 13 and 17 in Scotland.”

MARKETS.

OUT FLOWERS.—AVERAGE WHOLESALE PRICES. s. d. s. d.

Table listing flower prices: Anemones, Arums, Bourdians, Carnations, Daffodils, etc.

ORCHID-BLOOM IN VARIETY. s. d. s. d.

Table listing orchid bloom prices: Odontoglossum, Pansies, Pelargoniums, etc.

PLANTS IN POTS.—AVERAGE WHOLESALE PRICES. s. d. s. d.

Table listing potted plant prices: Adiantum, Aspidistra, Asplenium, etc.

ROOTS FOR THE GARDEN IN VARIETY COMING VERY GOOD.

VEGETABLES.—AVERAGE WHOLESALE PRICES. s. d. s. d.

Gros Colman, selected, p. lb.	4 0	Strawberries, per doz.	...	4	0-6 0
Melons, Channel Islands, each.	5 0	2nds	...	2	0-3 0

SEEDS.

LONSOS: *March 31.*—Messrs. John Shaw & Sons, Seed Merchants, of Great Maize Pond, Borough, London, S.E., write that naturally more orders now come to hand for Grass and Clover seeds; still the volume of business now passing is under the average, and the present season promises to be a late one. Meantime, prices all round keep exceedingly low. Some remarkable bargains are offering in Russian Red Clover seed, which closely resembles English-grown seed. Alsike well maintains the late advance. Tares are cheaper. The market for Mustard and Rape seed is firm. There is no change this week in Bird-seeds. Peas and Haricots realize former terms.

CORN.

AVERAGE PRICES OF BRITISH CORN (per imperial qr.), for the week ending March 27, for the corresponding period of 1896, together with the difference in the quotations. These figures are based on the Official Weekly Return:

Description.	1896.		1897.		Difference.
	s. d.	s. d.	s. d.	s. d.	
Wheat	21 10	27 9	21 10	27 9	+ 5 11
Barley	21 4	22 5	21 4	22 5	+ 1 5
Oats	13 4	16 3	13 4	16 3	+ 2 11

ARTIFICIAL MANURES FOR STRAWBERRIES AND Raspberries: *T. E. S.* Nitrate of soda or sulphate of ammonia, 200 lb.; precipitated phosphate, 500 lb.; kainite, 1000 lb. per acre.

BOOKS: An old correspondent wishes to dispose by private treaty of the under-mentioned standard works:—*Evelyn's Silesia*, 4th edition, by J. Hunter, 1812, 2 vols. 4to, bound in calf, gilt lettered. *Evelyn's Memoirs*, 2nd edition, by W. Bray, 1819, 2 vols. 4to, bound in calf, gilt lettered; all four books in good condition. Apply to the editor.—*J. G. B.* *A Popular Treatise on the Physiology of Plants*, by Dr. Sorauser, translated by Professor Weiss, Longmans (excellent for your purpose). *Elements of Botany*, by F. Darwin (Clay & Sons)—excellent. For *Fragrans Diseases of Plants*, by Talbot and Dr. W. G. Smith (Longmans). You send to be well supplied.

BRACKEN FERN: *T. A. H.* Take small portions of the rhizome with buds just starting, and plant them in a light soil mixed with a little peat, if possible. Spores would be a long business.

CHERRIES AND GOOSEBERRIES: *P. P.* Pannam's May Cherry ripens in the last week of May in the average of years, therefore several weeks before any variety of Gooseberry comes to us.

CONFEE SEED SOWING: *W. H. B.* All of those you mention may be raised in a large way by sowing in beds on well-pulverised and deeply dug, loamy land, the land as it is being dug should be raked with long (4-inch) toothed rakes, so that all large stones come to the bottom of the trench. Other men should follow with rakes of two or three different degrees of fineness, and render the tilth still more fine. If the weather continues fine, the land should be thrown into beds 4 feet in width, and the seeds sown thinly broadcast, and merely covered and no more by finely pulverised soil taken out of the alleys. The seeds should be protected from the sun by spreading thin canvas, mats, pea-sticks, &c., or a large percentage will fail to germinate. The land should be in good heart, but not recently manured; and the German method of raising a leguminous crop—say Lupines—the previous year, and digging it in is excellent in providing a mild kind of manure.

CYRIPEDIUM BONALII and **DENDROBIUM WARDIANUM:** *H. R.* Good, but not remarkable in any way.

DISEASED BULBS: *Williams.* The problem presented by the condition of the bulbs sent is one which is not easily solved. Many of them present externally more than one species of the common spongy moulds, but these are a consequence of decay and not the cause. Externally and internally most of the bulbs exhibit brown spots of rot, those of the Tulips in the most advanced condition, and upon these the microscope was employed with most success. The tissues, when reduced by the disease to a pulpy condition, present myriads of the small cells of an organism which resembles *Micrococcus anylivorus*, and like that, appears to flourish at the expense of the starch, with which, of course, these bulbs abound. The cells are nearly globose, about 13 microns in diameter, and either single or in pairs, or four together. When longer than broad, they measure about 14 by 2, so that they exceed those of the above named *Micrococcus*. These are the only extraneous organisms discovered in the present examination, and the problem to be decided is, whether they are the result or the cause of the decay. That similar bodies are capable of producing disease in plants at the expense of the starch, has been shown by the researches on the Pear blight in the United States, but in the present instance evidence is yet wanting to nite cause and effect. We can only say that the bodies indicated would be an efficient cause, that there are no traces yet found of any other probable cause. But, if they are only resultant from putrefaction, then the true cause has yet to be discovered, of which there is no indication in the present state of the bulbs. It is futile to talk of cure, for nothing can restore the bulbs when thus attacked, it can only be by prevention in the case of sound bulbs, and prompt eradication of all that are diseased. *M. C. C.*

EARLY VARIETIES OF STRAWBERRIES FOR MARKETING: *C. J. S.* King of the Earlys, rather small fruit, but good flavour; Royal Sovereign, a good all round variety, and well adapted for market; Auguste Niclaise has large fine flavoured fruit, and bears profusely. If you like old varieties, there are Keen's Seedling and Black Prince.

ELECTRIC LIGHT: *W.* This requires careful management, or the plants will be injured. The light should not be too near the plants, and should be enclosed in ground glass. We are not aware of any pamphlet on the subject. Much has been written in the *Gardener's Chronicle* about it, but we are much behind the Americans. The first account of the late Dr. Siemens's experiments was given in vol. xiii., 1881, p. 361, fig. 63. We have no leisure to hunt up all the references that occur in that and other vols.

EUPHARIS-MITE: *T. G.* This species of mite has nothing in common with red-spider. It infests other bulbs than those of Eucharis. If you will send an infected bulb to us, we will tell you if it has the bulb "mite."

EVERGREEN HEDGE: *Pro Bono Publico.* According to the decision of the Lord Chancellor and Lords Davey and Macnaghten in a tree-planting case, reported in our issue for December 1, 1894, no notice of the intention to lop need be given to the owner of the trees or hedge.

EXAMINATIONS: *R. J.* Apply to the secretary of the Royal Horticultural Society, 117, Victoria Street, but you are too late, probably, for this year.

FRENCH OR KIDNEY BEAN: *H. A.* If for a small garden or pot-culture, sow *Ne Plus Ultra*.

GASTERIA: *J. H. H.* From the Greek *gastero*, the belly, in allusion to the swollen condition of the leaves; "subverrucosa" means slightly warted; and "punctata," spotted. *Botanical Manua for English Readers*, published by L. Reeve & Co., would help you considerably, price a few shillings; or the Supplement to Nicholson's *Dictionary of Gardening*, if you could get it.

HARDY SHRUBS: *Correspondent.* If you know nothing about the subject, why read a paper on it, and why expect us to coach you up? We should gladly help you if we thought it would be of any use. In the meantime, look at Webster's *Hardy Flowering Trees and Shrubs*, and the same author's *Hardy Conifers, Gardening World Office*, Clements's Inn, Strand.

IVY-LEAVED PELARGONIUM: *F. H.* We do not find any fungus. You have probably syringed when the sun was shining.

LA REINE TULIP: *S. S. C.* This variety being white, flushed with rose, owing to something in the soil in your case, or by reason of much exposure to sunlight, may have the rose tint spread over more than the normal area of the segments of the flower. Try what shading with oil-canvas will do for them.

MAISONHAIR FERNS AND WEEVILS: *W. B.* The insects infesting the soil are weevils, very difficult to drive out of the pots, as there is nothing that you can apply to the soil to drive them out, but would kill the plants. We should be inclined to place them in a cold-frame for a week or two, and then place them in the shade, protecting them against frost at night, and cold biting winds by day, instead, keeping a frame over them, but with plenty of ventilation and moist surroundings. Having placed them on a coal-shaft, strew wood-shavings dipped in carbolic acid or coal-tar between the pots, the odour of which may render the frame distasteful to the beetles. The weevil grubs are even more injurious than the perfect insects, devouring the roots incessantly, but you might lessen their numbers by turning the bulbs out and examining them for the grub. If these means are ineffectual, you had better burn the lot and start anew with clean soil from another source.

MUSTARD-BLOSS: *R. B. W.* It may be obtainable from the wholesale seed houses or Mustard manufacturers.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*J. W. F.* *Colletia spinosa*, probably. Send when in flower.—*L. J.* *Pentapterygion serpens*.—*J. P.* *Iris fimbriata*.—*S. E. D.* 1. *Cepreus Lawsoniana*; 2, one of the varieties of *Thuya occidentalis*; 3, *Ficus orientalis*.—*A. E.* *Azalea*; we are unable to name the varieties of *Glehn Azalea*.

ONION: *H. A.* *Danver's Yellow*, a good keeper, and not particularly pungent; *James' Keeper*, and *Deftford*, if strong-flavoured, very long keepers are required.

PALM WITH SPOTTING ON THE LEAVES: *W. N.* Nothing can be observed on the leaves that affords the least clue to the cause of the spotting, and we should be inclined to think it is due to the use of artificial manure, to fumigation, or to noxious fumes of some sort.

PHEENX DACTYLIFERA: *R. B. H.* Unless you have made female plants, you will not succeed in obtaining fruits, the genus Phoenix being dioecious.

R. H. S. AWARD OF MERIT TO A CLIVIA: The Award of Merit given to *Messrs. Baldwin & Sons* for a fine *Clivia* at the last meeting of the R. H. S. rightly belongs to Mr. Bennett-Poë. We were misled by the official list of awards.

TOMATOES: *E. A.* Your plants are affected with some fungus, but we cannot tell which from the specimen sent. We fear the results will not be favourable.

TRANSPLANTED LARGE YEW: *W. S. T.* Keep them moist at the root, syringe the branches in the evening of dry and hot days, and place a mulch of litter over the roots. Some amount of shortening back the branches may be an advantage. The trees may not present a pretty appearance for one or two years, but they will doubtless quite recover from the removal.

COMMUNICATIONS RECEIVED.—*A. B.*—*W. H.*—*W. T. A. C.*—*C. de B.* *Tout vient à qui sait attendre.*—*Stanley Edwards.*—*J. A.*—*F. G.*—*Cartier & Co.*—*J. C.*—*Saunders* (next week). *H. W. CONTINUED LARGE INCREASE IN THE CIRCULATION OF THE "GARDENERS' CHRONICLE."

IMPORTANT TO ADVERTISERS.—The Publisher has the satisfaction of announcing that the circulation of the "Gardeners' Chronicle" has, since the reduction in the price of the paper, increased to the extent of more than 90 per cent., and that it continues to increase weekly. Advertisers are reminded that the "Chronicle" circulates among COUNTRY GENTLEMEN, and ALL CLASSES OF GARDENERS and GARDEN-LOVERS at home, that it has a specially large FOREIGN and COLONIAL CIRCULATION, and that it is preserved for reference in all the principal Libraries.

THE

Gardeners' Chronicle.

SATURDAY, APRIL 10, 1897.

SOME GOOD ROSES TO GROW FOR THE GARDEN.

NOTWITHSTANDING the lists which are continually given in the various gardening publications, and notwithstanding the official catalogue of the National Rose Society, it is remarkable how often one is asked what Roses would you advise me to grow? The answer depends upon so many different circumstances that it is not surprising that this must vary considerably. It may be thought that the present is an unfavourable time to entertain such a subject, as the time for planting is past; but is it so? Of course, the month of November is the time usually allotted to that; yet I have seen very good results from what I may call spring-planting, especially where the grower is near to a nursery where he can obtain his plants without the necessity of packing them up for a railway journey—and growers for sale have so greatly increased in number that there is very little difficulty in following out this plan. [This article should have been published at an earlier date, had not pressure on our space prevented it. Etc.]

The very first thing that has to be considered in this connection is, for what purpose are the Roses required? Are they for exhibition purposes or for home enjoyment, for it is very astonishing to see how the amateur, who never entertained the idea of exhibiting, gradually drifts into it, and therefore he does not want to be advised to choose anything except exhibition flowers; and he is also more inclined to ask for novelties than for any selection of the best older kinds. And so it comes to pass that it is mostly selections for exhibition purposes that are given to the public, and thus many varieties which are admirably adapted for the garden are excluded altogether.

Another question is, How does the enquirer mean to grow? Does he mean to take any pains with his Roses, such as the careful grower for exhibition does? Does he mean to disbud them, to look after the Rose-maggots, and keep them clear of aphids? or does he mean to put them into the ground just as he would any flowering shrub, and leave them to their fate? The answer to the question will also depend considerably on the locality. The most beautiful and useful section of the whole tribe I believe to be that of the Tea and Noisette Roses, but there are some localities in which it would be heart-breaking work to try and grow these. This will not depend,

as it is often thought, upon the northerly position of the garden, for I have seen them flourishing in great luxuriance in Wigtonshire, but then that county is under the influence of the Gulf Stream, and consequently its winters are not severe; so that unless in very bleak situations I do not think anyone need be deterred from attempting their culture. One sometimes hears and reads curious statements about them, thus, for instance, I read the other day that there are but few of them that open well out of doors; this is simply absurd. There are a few Teas which do not open well, but I should hardly think they are more than could be counted on the fingers of one hand; and it is just the same with H. P.'s. There are a few of them which are described as fair-weather Roses, that is, in wet weather the petals become fastened together, and being of a light texture they will not open, Jean Ducher, Souvenir d'Elise Vardon, and Madame Hippolyte Jumein, are of this character; but very often this complaint is made where Roses are disbudded for exhibition purposes, when consequently the blooms left are larger and with more petals. But one need not trouble oneself about these few, for what a wealth of beauty there is in the class! Take, for example, that most beautiful Rose, Marie Van Houtte, vigorous and floriferous; what shoots it throws up from early spring to late autumn! each shoot producing a number of blooms of exquisite cream colour, with, when in its best form, a beautiful edging of pink. I have seen bushes of this 6 or 8 feet high and nearly as much through, and at whatever time blooms were wanted, these bushes furnished them. Then there is that old and well-nigh forgotten vigorous grower, Homère, with its curiously-crippled bud and light-coloured flower, edged with rosy-pink. Nothing in the whole range of Roses surpasses in colour Ma Capucine, not even the Austrian copper exceeds it in brilliancy; it is very difficult to describe its colour, but the description given to it in the National Rose Society's catalogue comes as near to it as anything I can say. It is there said to be "bronzey-yellow, shaded with red;" unfortunately, it is not vigorous, and in some places difficult to keep, and if planted against a wall it loses a great deal of its colour. There is another Rose of recent introduction, which, for some unaccountable reason, has been classed among hybrid Teas—I mean Gustave Regis; the flowers are of a beautiful nankeen yellow, with a long pointed bud; the petals are few in number, and consequently it soon opens, when it becomes useless—at the same time it is so beautiful in bud, it cannot be well dispensed with. Dr. Grill is another of these curiously coloured Roses, it is not very vigorous, but as it is free flowering, and of a distinct shade of colour, it should find a place in the garden; nor must I omit L'Idéal, which is, however, more of a Noisette than a Tea, in colour a beautiful metallic-red tinted with yellow and Apricot; in fact, it is one of those indescribable colours which we often find in this class. Madame Charles, again, is an old Rose, but a very beautiful one; the colour is a bright Apricot, it bears a striking resemblance to Safrano, but is more vigorous in habit. Madame Chédane Guinoisseau is another Rose that I would strongly urge amateurs to grow, it gives a never-failing supply of buds at all seasons; it is not large, but it is very bright and pretty, the colour being a clear bright yellow, and the bud makes a fine buttonhole. I have written so lately upon the subject of

climbing Roses, and therefore think it unnecessary to mention the numerous beautiful varieties of the Noisette section, which, wherever there is a wall or fence ought to find a place in the garden; nor have I gone into the splendid exhibition varieties of Teas which are always sure to be given when a selection is asked for, but have confined myself to those which are desirable for especially making a show in the garden.

Of the many wonderful beautiful varieties in the hybrid perpetual class there is a considerable number which, although counted as exhibition varieties, are also very effective for garden purposes; for instance, what more beautiful Rose for the garden can there be than old General Jacqueminot, which was sent out by Rousselet in 1853—forty-four years ago? it has been the parent of a good many Roses since, and yet one often sees it now carrying off the medal for the best Rose. As a garden Rose there are few that can rival it; it is vigorous in habit, free-flowering, brilliant in colouring, and very fragrant. There is another Rose which, because it is not an exhibition variety, is often overlooked—I mean Gloire de Margottin, the last Rose raised by my old friend Margottin, of Bourg la Reine, one of the shrewdest and keenest of French rosarians; indeed, I can only recollect one other who could vie with him in this respect, Lacharme of Lyons—they were both rough diamonds, but I recall with much pleasure many a "crack" I had with Margottin in his pleasant garden. Gloire de Margottin is very bright, somewhat loose in habit, but very vigorous, and therefore suitable for a pillar. Empereur de Maroc is an old Rose, which seems to be nobody's child, as it does not occur even in the National Rose Society's catalogue of garden Roses, yet I know of no darker Rose, or one which, from its free-flowering qualities, is more satisfactory; it is of a rich deep velvety-crimson colour, reminding one in colour of that very uncertain Rose—Sir Rowland Hill. Gloire des Rosamanes, again, is a most brilliant coloured Rose, closely approaching scarlet, not very full; indeed, it may be better described as a semi-double Rose, and there can be little question, I think, that in one way or another to its influence may be attributed some of our most brilliant H.P.'s. There is a class of H.P.'s which may be considered rather as hybrid Noisettes. They are usually classed amongst the H.P.'s of which I think Boule de Neige may be regarded as the most favourable specimen; it is of vigorous growth, flowering in clusters, and as its name imports, a pure white, and therefore forms a striking contrast to some of the Roses already mentioned, and for this reason, and its freedom of flowering, ought not to be omitted. Gloire of Cheshant, raised by Messrs. Paul & Son, is a very brilliant shaded crimson-coloured Rose, and, for its habit of freedom of flowering, makes a capital bush. I hardly like to omit John Hopper; for, although in its colour there are many varieties which exceed it, I have always felt a sort of paternal fondness for it, as it was by my advice that Mr. Ward, the raiser, after his disappointment at its rejection by the Royal Horticultural Society, was induced to bring it forward again, when it was duly recognised, and, I believe, brought considerable gain to the raiser. It is a very early Rose, and very sweet. Of course, there are many other Roses of other classes one might mention; my object has been rather to recommend some which I think are pretty sure to give satisfaction to those who love a garden. *Will Rose.*

NEW OR NOTEWORTHY PLANTS.

EPIDENDRUM PORPHYREUM, *Lindley.*

Of the large genus of Epidendrum, there is but a very limited number of species which, through their large, ornamental, or finely-coloured flowers, are of value to horticulturists. Of this small number, *E. porphyreum* stands in the foremost rank. But naturally, this species belongs to the Polycladia, with large pyramidal thyrse; but in regard to the appearance of the stalks, leaves, thyrse, and form of the flowers, it has a strong resemblance to *E. paniculatum*, Ruiz et Pavon, excepting that the flowers are somewhat bigger, and of very different colour. As a species, it is easily distinguishable by some marked discrepancies of the lip. The plant forms a dense tuft of from six to fifteen stems, having a height of 50 to 100 cm., and a thickness of the little finger; and they are distichously set with herbaceous, oblong, upper-sides brownish-green, under-sides magenta, purplish leaves. The panicle is many-branched, pyramidal, with arching tips, often 25 cm. high, and very thickly set with flowers. The sepals are oblong, spatulate, of a beautiful shining reddish-vivelline colour. The petals are of same shape and colour, but much narrower. The lip is trilobate, sometimes of tender rosy tint, but mostly of a delicate orange-yellow colour. The column is of the same colour as the lip. *E. porphyreum* is found in Colombia and Ecuador, but is very rare. It grows in dense woods on trees, from 1900 to 2100 metres (6175 feet to 7800 feet) above the sea, and flowers from November to February, when it is a charming sight to behold these localities. In cultivation it requires the same kind of treatment as *Odontoglossum cirrosium*. *P. C. Lehmann.*

FLORISTS' FLOWERS.

EARLY SINGLE TULIPS.

On looking over the extensive display of early single Tulips staged in the Drill Hall at the last meeting of the Royal Horticultural Society, one could not help being struck by the fact that but little of real novelty has put in appearance during the past few years, which is perhaps not surprising, seeing how high is the quality of many of the standard varieties, and the consequent difficulty of obtaining advances upon them. Among the white-flowered Tulips, the white form of Joost Van Vondel, which it is believed emanated as a sport, is deservedly at the head of the list, being much deeper in the petals than the old white Pottebakker, and purer in colour. This, and the crimson-scarlet and white Joost Van Vondel, make excellent bedders, as can be seen in our London parks; while the stiff stalks and thick petals of White Pottebakker enable it to withstand rough weather. White Lady is very large, and somewhat coarse. Nelly is a pleasing white, but not so pure as the white Joost Van Vondel, and is said to freeze well. The Silver Bride of Haarlem is a very fine white, well deserving of culture, and is probably a little dear in price at present.

Among the yellows, Uphir d'Or is supreme, large, rich in colour, and strikingly handsome. Yellow Pottebakker, when purely of a self colour, is a most useful variety; and the old Golden Prince holds its own for bedding purposes. Thomas Moore, an old terra-cotta self, was seen in Messrs. Cutbush & Sou's collection, distinctly feathered with amber, and though bearing the old name, is apparently distinct enough to be classed as a variety.

Of bright crimson varieties, nothing can touch Vermilion Brilliant; it is prominent for colour and striking appearance. Joost Van Vondel will sometimes come as a maroon self, very fine and deep. Bacchus and Couleur Cardinal, both dark crimson, are excellent bedders, dwarf, and standing rough weather—the last named the latest in flowering. Koh-i-Noor, rich, dark scarlet, is somewhat new, but will like high rank in this section.

Of purple and violet shades, Vander Neer, bright violet purple, and Wouwerman, deep purple, still hold

their own, whether for pot-culture or bedding; beds of the two named are always features in our London parks.

Proserpine is unbeaten for its large and handsome rosy-carmine flowers, and as an effective bedder it is almost without a rival. Like Vermilion Brilliant, it is in so much request as to be somewhat high-priced. La Géante, a large bright rose variety, is highly spoken of.

Among the edged flowers, for size and beauty there is nothing like Keizer's Kroon, and a large bed of it containing several hundreds of bulbs is a sight long to be remembered. It has one failing—the delicate yellow feathering becomes scorched under the hot sun. It is the largest of the early single Tulips, and one of the finest for exhibition purposes. Cerise Gris-delin is a beautiful variety—a pinkish-rose ground, sometimes deeper, feathered with white. Le Matelas, deep rose, edged with white, is very pleasing also.

Of distinctly striped Tulips there are few. Roi Pepin, when true to character, has a white ground striped with red or carmine, and is decidedly handsome. Van Vondel will sometimes come striped, but it is not a fixed character. Bride of Haarlem is a good and useful old scarlet-and-white striped variety.

There are several handsome flushed varieties, such as Fabiola, deep rose, feathered and flamed with white; Rose Gris-delin, delicate pink, flamed with rose; La Grandeur, white, with flushes and flames of rosy pink, but it has somewhat pointed petals; and Prince of Austria, almost a self, orange-red, flushed with a deeper colour, more especially on the insides of the petals.

The six finest early single Tulips are Keizer's Kroon, Uphir d'Or, Proserpine, Vander Neer, white Van Vondel, and Vermilion Brilliant. *R. D.*

KEW NOTES.

RHODODENDRON METTERNICHI. — Although not exactly a new plant, this is one of the rarest and least known of the species in cultivation. It is interesting as one of the very few true evergreen Rhododendrons found wild in Japan, there being only one, or at most two, other species indigenous to that country. The *Azalea* section of the genus is, on the other hand, well represented. *R. Metternichi* is now in flower at Kew, and proves to be an ornamental species, although in the view of many a drawback will exist in its flowering as early as the end of March. The sharp touch of frost on March 29 did, indeed, destroy several trusses of flowers then open. The leaves are leathery and very firm, 3 to 4 inches long by 1 to 1½ inch wide, with a cartilaginous margin and an abruptly pointed apex; beneath, they are covered with a felt-like substance, which varies in colour from brownish-white to deep reddish-brown; the petiole is 1 inch long and transversely wrinkled. The flowers are set rather loosely in the truss, and are borne on stalks 1 inch long, the pale pinkish-purple corolla measuring 2 inches across. The green calyx is very small and inconspicuous. Siebold figured this Rhododendron in his *Flora of Japan*, t. 9, and depicts it with seven segments to the corolla. The living specimens at Kew, as well as the dried ones in the herbarium (gathered by Maximowicz and Maries), have only five. Siebold describes it as "inhabiting the mountains of Northern Japan, being found most abundantly in the Nikko Mountains. It is planted about the tombs of the Emperors of Japan, and in the groves that surround sacred places." Professor Sargent saw it also in great masses by the shores of Lake Yumoto. Of the species in cultivation, I should judge it to be most nearly allied to the Caucasian *R. Smirnowii* and *R. Ungeri*.

PRUNUS SUBHIRTELLA.

In 1862, this Cherry was collected in Japan by Richard Oldham (the Kew collector), and subsequently by Maximowicz, but until within the last few years it appears to have been quite unknown in cultivation. There is a single young tree at Kew which flowered there in April, 1886, and towards the end of the year a figure of it appeared in the *Botanical Magazine*. It is now flowering for the second time, and although as yet too small to show its full beauty,

it is of great promise. It grows vigorously, and is perfectly hardy. The habit is erect, and the pale rosy flowers—each half an inch across—appear before the leaves. The latter, however, when fully grown, are about 3 inches long, ovate, toothed, and pointed. This Cherry has many points of resemblance to the lovely *P. pendula*, whose drooping branches are now laden with delicate rosy flowers. The flowers of the two are, in fact, identical, but whilst the leaves of *P. pendula* are glossy, those of *P. subhirtella* are dull green, and more distinctly hairy both above and below. The habit supplies the most obvious distinction, but the fruits would probably be needed to definitely settle whether they are specifically distinct.

RHODODENDRON CAMPTLOCARPUM.

The more common colours among evergreen Rhododendrons are, of course, rosy-red, purple, and white; pure blue is entirely absent, although some of the purples decidedly approach that colour. Yellow, especially among the larger species, is rare, and it is on account of its having flowers of that colour that this Himalayan Rhododendron deserves notice. Its nearest ally is the crimson-flowered *R. Thomsoni*, and it has, like that species, leaves whose underside is of a vivid glaucous hue. It may even, out of flower, be mistaken for it, but, as a rule, the leaves of *R. campylocarpum* are smaller, and of a paler green on the upper surface. The flowers appear in a loose truss, each one being about 2 inches across. The yellow of the flowers is of a somewhat primrose shade. A couple of plants are in flower in the Rhododendron dell at Kew. As the species has been grown outside at Kew for several years (in sheltered positions, but without artificial protection), it may reasonably be included among the hardy Himalayan species. To those whose gardens have been found to suit the better-known *R. Thomsoni*, its distinct colour may command it. The two are of the same degree of hardiness.

PRUNUS TRILoba.

Of all the shrubby *Prunus* the double-flowered variety of this species is, in my opinion, the most beautiful. On a wall at Kew, an old specimen, probably one of the oldest in the country, is each spring a mass of blossom, and just now it is in its greatest perfection. Every shoot is loaded with rosy-white flowers which, although double, are not so much so as to give them the lumpy appearance that spoils so many double flowers. The leaves are toothed, and a deeper indentation at each side frequently gives them a slightly trilobed character, to which the name refers. This double-flowered variety was originally introduced by Fortune from China in 1857, but until quite a recent date, the single-flowered typical plant was unknown in Europe. It was, a year or two ago, obtained for the Kew collection, and is now flowering there. It has almost pure-white flowers, which, besides being single, are much less in diameter than those of the other. The leaves are of the same shape and character, but small; the whole plant, indeed, lacks the strength and vigour of the double-flowered variety, and cannot be compared with it in beauty. *H. J. E.*

MELON-GROWING IN HOT-BED FRAMES.

In recent years Melons have been less and less grown in frames, the water-heated bed in a span or lean-to house being more convenient and handy, and for early fruits this mode of cultivation is indispensable. However, there are still gardeners who must grow their Melons in frames, and they manage to produce excellent fruits after May. It is a question of warmth, together with efficient ventilation—not an easy matter in the spring, with the ordinary hot-bed.

Most gardeners know how to prepare the materials for making a hot-bed, and they are aware that the careful preparation of the leaves and stable manure is a matter of importance. If the stable-manure is much used before it reaches the gardener, less of it should be used than if it be only stained—say one-third to two-thirds of tree leaves; and in the latter

case manure and leaves may be equal. A hot-bed should not be less than 3 feet 6 inches deep at the front, or 4 feet at the back; and if it can be made in a trench sufficiently wide to accommodate the bed and its linings, the heat will be proportionately

with a large proportion of the long straw towards the outside of it, place the frames thereon, and wait till the heat rises and the rank ammonia fumes have passed off, by which time the heat will have declined somewhat.

the hills, others boards, slates, &c., 3 feet in width, so as to keep the roots in a measure from getting into the manure too soon, and prevent uneven sinking of the soil. The latter may contain lime-rubbish, and if it be poor lean a small quantity of horse-dung in a rotten state may be added. Some gardeners plant two Melon-plants together, but I prefer planting them singly at 18 inches apart, training one towards the back and the other towards the front alternately, the soil being brought pretty near to the glass, so that the plants have abundance of light. If the heat remains right no shading will be required, if due attention be paid to giving air; but should the plants flag, a slight shade for an hour or so when the sun is strong should be employed till the roots have taken to the new soil, after which no shading should ever be used. Newly-made hot-beds always require care at first, the heat rising rapidly by sunheat, and so scalding the leaves. It is advisable to always leave a small amount of air on at the back of a frame at night.

In training the young Melon-plants some gardeners nip the points above the third leaf, the result being that two shoots are made, which are trained one upwards and one downwards, and so soon as 2 feet more growth have been made, the points are again nipped, when the side laterals break strong, some of these may be removed altogether, leaving say, three or four on each side—these, as a rule, will show fruit; 70° by night, and 80° by day, will suit the growth. If, however, these lateral shoots produce no female flowers, they must be stopped again at the first joint, when the next break will almost be sure to bring them.

In growing Melons in frames, it is of importance to keep the foliage thin by constant thinning, not leaving it for a week or longer, and then have a great mutilation of the plants carried out. If the bine is not to be stopped at the third leaf, then train one bine up and the other downwards, and when they have grown to within 8 inches from the ends, then pinch out the points, train out a selected number of laterals, and stop them at two joints above the female flowers. Keep the frame a little drier while setting is proceeding, and use the pollen when both male and female flowers are dry. The plants ought not to get dry at the roots during this period, for I have observed that by keeping the soil in a fairly moist state, there is little trouble in getting plenty of fruit to set. With most varieties, four good Melons on a plant are sufficient; and this number will ripen quicker and be better in flavour than a heavier crop.

Air must be admitted carefully at all times during early growth, and moisture afforded more or less according to outside conditions. In hot, dry weather the frames may be closed early, say, at 2 P.M., after gently dewing the plants over-head with tepid water. The fruits should be raised up towards the glass on flower-pots, &c. The splitting of Melons is due in a great measure to the soil getting very dry and then being deluged with water. When the fruits are approaching ripening, the soil should be allowed to get fairly dry. *H. Markham.*

FRITILLARIA PLURIFLORA.

WE are indebted to Mr. Gumbleton for the privilege of figuring this elegant species. The illustration (fig. 76) tells its own tale; but, for the convenience of the reader, we append the description from Watson's *Flora of California*, vol. ii.:

F. pluriflora, Torrey.—Bulb of large, thick scales, a half inch to an inch long; stem stout, a foot high or more, four to twelve-flowered; leaves eight to fifteen, nearly covering the stem, somewhat verticillate, narrowly lanceolate, 3 or 4 inches long; flowers nodding on long pedicels, uniformly reddish-purple; segments somewhat spreading, 9 to 12 lines long, oblanccolate; nectaries obscure; stamens unequal, 6 or 7 lines long, shorter than the style; anthers 2 lines long. Benth., *Pl. Hartweg*, 333; Baker, in *Journal of Linnean Society*, vol. xiv., p. 270; on the *Upper Sacramento*, Hartweg; and on the *Eastern River*, Fremont. Peculiar in the size of its bulb.

FIG. 76.—FRITILLARIA PLURIFLORA.

economised, as compared with a bed built on the level, with the wind having access to it on every side. In tenacious soils such trenches or pits must be drained in some manner.

Having made the bed in a fairly solid manner,

The soil-hills of sound loam may now be put in, and a further wait made till these get warmed, no planting being done till the thermometer, when planted in a hill 6 inches deep, shows a warmth of 85°, not higher. Some gardeners use turves under

ORCHID NOTES AND GLEANINGS.

STENOGLOTTIS FIMBRATA.

THIS pretty terrestrial Cape Orchid has foliage that is undulated at the margin, and arranged in a clustered mass at the base of the stem. The spike is usually 9 inches in height, and bears a number of rosy-pink flowers, the most noticeable part of which is the blotched and spotted purple-coloured trifold lip. It is a plant easily grown in the intermediate-house if afforded a loamy compost and a few crocks, so as to give it ample drainage. Propagation is by means of the side-growth. A good figure of this plant is given in the *Bot. Mag.*, t. 5872. R. L. H.

EULOPHIELLA ELISABETHÆ.

Having read the remarks of several writers in the *Gardeners' Chronicle*, I should like to state our method of treatment, which seems to suit the needs of the plant exactly. The plants are cultivated in a warm, moist corner of the East Indian-house; they are afforded liberal waterings at the roots whilst in active growth, and never at any time allowed to become dry. The plants are grown in flower-pots, in a compost consisting of fibrous peat, sphagnum-moss, and leaf-mould, all being chopped up and well mixed together with some small crocks, the pots three-parts filled with drainage material. There is a specimen of *Eulophiella Elisabethæ* in flower in these gardens which possesses three stout flower-spikes, the longest of which measures 17 inches, and has twenty-nine expanded blossoms and unopened buds, and the other spikes have each eighteen flower-buds. The largest leaf is 3 feet 2 inches long and 2½ inches broad. D. Masterton, gardener to J. C. Parr, Esq., Grappenhall, Heyes, Cheshire.

ORCHIDS AT CAMDEN WOOD, CHISLEHURST.

Those persons who are acquainted with the extensive collection of Orchids at this place can speak of the intelligence and skill of the cultivator. On the occasion of a visit made to the gardens late last month, many rare and beautiful Orchids were observed in bloom, forming an imposing display. Amongst others, *Cypripediums* were conspicuous; *C. Harrisonianum* superbum, *C. Lathamianum*, *C. Calypso* (Oakwood var.), *C. pulchellum roseum*, *C. Measnerianum*, *C. Creon superbum*, and *C. superciliosum*. Of species and varieties of *Ostiaea* there were *C. Trianei* Robert Measurae, *C. T. Sandere*, *C. T. alba*, all very good and distinct. A plant of *Lælia cinnabarina* was also conspicuous; many forms of *Dendrobium nobile* were noted, including *agrard D. n. nobiliss* and *D. n. Sanderiana*; *Coleogyne cristata alba*, *Cymbidium Lowianum superbum*, a gem of a plant; the beautiful crosses, *Cymbidium sbrucei-Lowii*, and *C. Wintianum*, valuable and distinct Orchids that flower freely at this season. *Odontoglossum crispum* in fine form were noted, including the variety *O. c. Arthurianum*, which received a First-class Certificate in March, 1896; and *O. c. Princess*, which last year was awarded an Award of Merit; *O. c. Cooksoni*, the lovely *O. c. Dormanianum*, and numerous forms of *O. Rosii* majns, *O. Roezli*, *O. adspersum*, *O. Humannum*, well-flowered specimens of *Sophronitis grandiflora*; and very many were the novelties not at present in flower, as for instance, *Cypripedium insigne Sandere*, and *C. i. Sanderiana*, *C. Lawrenceanum Hyenanum*, &c.; and amongst *Cattleyas*, *Lord Rothschild*, *Clusia superba*, a Veitchian hybrid between *C. gigas* and *Lælia elegans* Turner; *Cattleya Prince of Wales*, *C. Broomfieldensis*, *Lælia Cattleya eximia*, *L. C. Fowleri*, and others of value. The condition of the collection leaves nothing to be desired. Mr. Robbins, the gardener here, is turning his attention to hybridising; many good hybrids are fast arriving at the flowering age. Alfred Outram, F.R.H.S.

DENDROBIUM × RUBENS GRANDIFLORUM.

Dendrobium × rubens was obtained by Mr. Jas. Cypher by crossing *D. × Ainsworthianum* Leechiana with *D. nobile nobiliss*, and the beautiful and

richly-coloured cross was described in the *Gardeners' Chronicle*, February 25, 1893. Some more recently-flowered plants of the same batch have produced another form which has flowers much larger than the original, and to which the name *grandiflorum* has been attached. A fine flower sent by G. W. Law-Schofield, Esq., New-Hall-Hey, Rawtenstall, Manchester (gr., Mr. Shill), proves that the ability to give large flowers is constant, at all events, when the subject is properly grown. The form of the flower, and especially of [the large downy labellum, with its dark crimson-purple disc and rose-purple apex, is like a fine *D. × Ainsworthianum splendissimum*. The size and bright violet-purple colour of the sepals and petals resemble *D. nobile nobiliss*.

A precisely similar variety is also sent by Mr. Charles Maynard, gr. to Mrs. Ames, Langwater, North Easton, Mass., U.S.A., with the memorandum that it was obtained from *D. nobile nobiliss* × *D. × splendissimum grandiflorum*.

CYRTOPODIUM PUNCTATUM.

The terminal portion of an inflorescence of this fine old Orchid, kindly sent by J. Fineberg, Esq., Sandy Mount, Birkdale, shows its peculiar character of producing large and showy yellow floral bracts, spotted with red-brown, in a very prominent manner. Here and there a perfect yellow and brown flower appears, but in the majority of instances the short lateral branches destined to bear flowers have either wholly failed, or the flowers are abortive and inconspicuous. But the beauty of the inflorescence does not suffer, for several of the bracts are produced together, and form what any one not inspecting it closely would take for flowers, and very pretty ones too. Some of the larger bracts are 2½ inches long and 1½ inch broad. The plant is also known in some gardens as *C. Saintlegerianum*.

EPIPHYLLUMS.

ATTENTION has been directed in the *Gardeners' Chronicle* to the beauty of this useful group of plants, together with an expression of regret that so few are grown. Some years ago I grew the best varieties largely, and in the course of years I have assisted in grafting some thousands. *Apropos* of the latter part of the work, I have still a vivid recollection of potting some 3000 stocks of *Pereskia aculeata* in 3-inch pots, ready for grafting later on, and well remember the pain inflicted by their very sharp, and to me, poisonous spines. As the method adopted differs slightly from that described in your recent issue, I may be allowed briefly to refer to it here. For grafting purposes only the one stock, viz., *Pereskia aculeata*, was then employed. [P. Bleo, figured in the *Gardeners' Chronicle* recently, is better. Ed.] Fresh young growths of these were taken as cuttings when 4 inches long, and inserted in very sandy soil in pots heavily drained. At all times water was given sparingly; the cuttings being inserted at any time when procurable, but preferably late in the summer. With little or no care the majority of these were soon rooted, and when this ensued a quick growth followed, and the plants were potted usually in the spring, singly in 3-inch pots, the plants being topped at from 12 to 18 inches high according to strength, and a straight stick put to each. Early in May the *Pereskias* were placed in frames in the open, so as to secure a moderately firm growth, and be ready for grafting in the autumn ensuing. The "spring" is given as the time for grafting, whereas late autumn was always preferred in my own experience, for the reason that the growths were then well matured without any excitable tendency, as may be expected in spring with returning growth. The grafting is very simple, consisting merely of taking the pot with stock between the knees (the operator being seated), cutting off the head at the required height horizontally, and then making a slit an inch or so deep, longitudinally, when the graft was in readiness. One section only of the flattened pieces of

growth was employed as scions, and these generally of the current season's growth, so as to purposely avoid the hard midrib of the older stems. With a sharp knife a slight shaving of the bark was removed from either side of the midrib of the scion, the stock opened and the graft inserted while the viscid sap remained fresh. Care was taken, as far as circumstances permitted, not to cut beyond the midrib in preparing the scion, the latter being always inserted centralwise in the stock so as to insure a good footing on the one hand, and a head uniformly balanced on the other. The scion may be secured in position by the use of raffia or by pinning to the stock with the spines of the stock—if with the former, it must be done lightly, or the soft succulent growth is cut right through. In any case, however, the use of a spine will keep the scion in position while the tie is being made, and may also remain there placed. No grafting wax or similar material is at all necessary; and when the grafting is finished, a close frame in a greenhouse at a temperature of 45° or 50° will suffice for about three weeks, when, if all goes well, the union will be effected. The plants may then be placed on the stages in the greenhouse, affording water very sparingly. Late in March, or early in April, these freshly-worked plants may be repotted into 5-inch pots, using loam as the principal, with plenty of grit and mortar-rubbish, and about one-sixth part of peat and charcoal. Potting or repotting must always be carefully done, as not infrequently the breaking of the ball of earth will cause the plant to shrivel and die, as roots are only very sparingly produced. One item in the culture of these plants as now advocated was a cool temperature at all times, the plants being always brought into bloom in a rather cool greenhouse with a temperature of about 45°, or a little more, the plants flowering through November and December each year, and lasting a long time in fine condition. There is no need to forward any of these in a warmer house, as suggested by your Cheshire correspondent, as there is considerable difference in the varieties themselves in this respect where a collection is grown, and where the flowers are opened in heat, they are not so durable after. Throughout the summer months, all the plants, young and old, were grown in a sunny frame in the open, air being given freely, water at the root sparingly, and on the hottest days the plants were gently sprayed over with water from the syringe at closing time. In this way a free compact growth was secured, in which firmness, as also short sturdy stems were generally noticeable, while an abundant flowering was always secured. Firm potting is an essential in the culture of these plants, and frequently failures may be traced directly to a soil conspicuously loose about their roots that retains moisture far in excess of the requirements of the plant. Indeed, failures generally may be attributed to, firstly, an overmoist soil at all times; secondly, too much heat, and loose potting. During the autumn months, when these plants are at their best, nothing is finer for decorating the greenhouse or conservatory. It is worthy of note, that by the above mode of culture the plants were generally freely set with bloom-buds when brought from the frames to the greenhouse, but on stocks other than this, or again on their own roots, the plants flower at different periods, as may be expected. J.

EPI-CATTELEYA × MATUTINA.
(CATTLEYA BOWRINGIANA?, EPIDENDRUM RADICANS?)

NOT the least interesting point about the work of the hybridist is the unexpected results which are produced during his labours. Few who were asked to describe what they considered the progeny of *Cattleya Bowringiana* as a seed-bearer crossed with *Epidendrum radicans* would be like, would venture to picture to themselves a plant so like the male parent, and so utterly unlike the one which bore the seed as *Epi-Cattleya × matutina*, exhibited by the raisers, Messrs. Jas. Veitch & Sons, Ltd., of Chelsea, at the Royal Horticultural Society on March 23, 1896, to be. A glance at the illustration (fig. 77) shows that

the plant has much the same habit as *Epidendrum radicans*, even to the air-root bearing characteristic of that species. The base of the stem showed a tendency to thicken, which may increase with age, but up to the present there is little evidence of the *Cattleya*. In the flowers, too, it will be seen that the character of the labellum does not appear to be

NOTES ON THE NARCISSUS.

(Continued from p. 200.)

DISEASES OF THE NARCISSUS.—A very great deal has been written of late years, since *Narcissus* growing for pleasure and profit has become so general, upon the so-called disease "basal rot," its causes and cure,

with its own ascertained or possible antecedents, but simply the failure of its action in the plant when its environment is found un-suitable. When an entire genus of plants has been searched out and brought into cultivation, it is not surprising that the welfare of some of its varieties should be found to depend upon the presence of certain special conditions difficult to determine and to supply when found. We have in our gardens *Narcissi* directly imported, or the offspring of importations, from lands as far apart as Switzerland and North Africa, from the sea-level, and from 6,000 feet of mountain altitude, so no marvel if they are not all quite at home in England. The disease (the word is convenient, though inaccurate) is not a fungoid disease propagated by spores, and is not contagious. No single explanation of its presence, though every explanation may be true in part, covers the whole ground.

The one most commonly offered is that this failure results from the application of crude ammoniacal manure, and it is true that the white trumpet *Daffodils*, most wild *Narcissi*, and the *N. spurium* section, such as Golden Spur, sicken in ground loaded with rank farmyard manure. The sand of the Dutch bulb-farms has for many generations been very heavily dressed with cow manure for the cultivation of *Hyacinths* and *Tulips*; and bulbs of Golden Spur coming from Holland commonly have a black, almost charred appearance, and to the practised eye show clear signs of the imminence of basal rot, unless given a change of soil. But it is by no means universally true that the *Narcissus* dislikes nitrogenous food. The large growers in the Thames Valley bring back from London in their market vans enormous quantities of fresh stable-manure, and plough it into their *Narcissus* quarters before planting, and the growth is benefited by it both in flower and bulb. On an extensive *Narcissus* farm in Mount's Bay, Cornwall, I was this spring shown an acre of reclaimed marsh land which had received no less than a ton of quarter-inch bones, and a liberal dressing of woollen refuse. The bulk of such manure is phosphatic, and gradual in action; but the plants were evidently fastening on, and greatly enjoying the large percentage of immediately available nitrogen. That a glut of nitrogenous food is the sole cause of basal rot is sufficiently disproved by the fact that a very large proportion of my own seedlings invariably die in this way before flowering, though always planted in beds of pure loam, burnt soil, and other non-nitrogenous materials. It is certain that some *Narcissi*, liable to basal rot in cultivation, will establish themselves healthily in grass; and this fact is often alleged as a proof that the sickness is induced by rich soil. But in my garden these kinds die out if planted in the very same turf broken up and tilled without the addition of any manure whatever; and it is difficult to believe that such ground absorbs, in one season, sufficient nitrogen from the atmosphere alone to poison the plants. It is my belief that the protection against frost given by the thick matting of grass fibres has much to do with the well-being in turf of such *Narcissi*. This view is supported by the observed fact that my garden is comparatively free from basal-rot after mild winters, and especially when the young foliage has escaped injury by frosty winds in early spring.

I have often been struck by the fact that the *Narcissi* most prone to this sickness all bear seed with great regularity, and in abundance; also that some of them, e.g., *pallidus* *precox*, increase slowly or scarcely at all from the bulb. May it not be argued from this, that in our endeavour to multiply *Narcissi* solely by bulb-division we are violating Nature's provision of increase by seed; and that the rational and successful way of growing many kinds is by seed?

Basal-rot has been by more than one writer attributed to the attack of mites (*acar*), because they may not uncommonly be discovered in the decayed substance at the base of affected bulbs. It is not certain that the mites, having been attracted by diseased bulbs, will not then pass on to and injure adjoining sound ones, but, from the very large number of decayed bulbs examined by myself and others microscopically, and found to be without

FIG. 77.—EPI-CATTELEYA X MATUTINA. (SEE P. 232.)

fixed, for one exhibits a distinct attempt at a trilobate form, and is different from the others. The sepals and petals are yellow, tinged with vermillion; the lip, yellow at the base, reddish in front. Like other crosses with *Epidendrum radicans*, it will doubtless improve when thoroughly established, and like them be easy to grow and propagate.

but no wholly satisfactory or helpful diagnosis or remedy has been forthcoming. The reason seems to be—and I have been led to the conclusion after many years of careful observation in my own garden and elsewhere, and after much correspondence and reading of all that has been advanced by others on the subject—that basal rot is no truly specific disease

trace of mites, I entertain no doubt whatever that their presence is a consequence, not a cause of the malady.

In brief, any adverse condition, whether excess of food or unsuitable food, the shock of severe cold and the irritation of alternate frost and thaw, prolonged drought, absence of ripening sun in summer, the perpetual multiplication by bulb-division instead of by seed, may make the Narcissus ill at ease, and the symptoms of this discomfort appear in a paralysis and decay of its most vital part, the basal plate or disc whence its roots issue.

Twice I have noticed the appearance upon leaf, stem, and flower of my Narcissus of a brown blotch, which had quite the appearance of a fungoid affection, and evidently spread from leaf to leaf and from plant to plant. My flag-lice were visited by the same thing at the same time; indeed, it appeared to attack them first, and thence to spread to the Narcissus. Experts to whom leaves were submitted failed to identify it with any known fungus, or to establish its fungoid character; but from its infectious character, and from its disappearance after a persistent spraying with ammoniated copper-carbonate, I have little doubt that it was of this nature.

The Narcissus-fly (*Merodon equestris*) is not a disease, but may be briefly mentioned as a plague, which would prove troublesome if it were to obtain a lodgment. Fortunately, our climate does not seem to attract it as a permanent resident. It sometimes comes, of course, in the larva form, in considerable quantity, from Holland, and it is well to handle all Dutch bulbs of Narcissus, and cut open any that are soft and compressible, to discover and destroy the white grub. The insect has been figured in all states in the horticultural journals; and its life-history is fully described in a *Monograph*, by Dr. J. Ritzena Bos, G. H. Englehart.

THE WEEK'S WORK.

THE HARDY FRUIT GARDEN.

By H. W. WARD, Rayleigh, Essex.

Taking Down Blinds from Fruit Trees.—Advantage may be taken of a fine day to take down the cloths which have been used during the last seven or eight weeks to protect the blossoms upon Apricot-trees from frost. Roll them up together with the ash-line and loops, and after they have been tied and labelled, put them away in a dry place for future use.

The upright poles and coping-boards should also be stored away. The cross-beams in a barrow- or cart-shed make a suitable place, and they should be stored so that they may be taken down next year without having to remove the poles and boards belonging to the Peach and Plum walls. Should there be any difference in the heights of the several walls on which the protecting material has been used, a label indicating the wall to which the respective poles belong should be attached to each. The blinds must be retained on Peach-walls a week or two longer, so that they may be used should occasion require them, remembering that what is not prevented in such cases cannot be cured. Trees that require blinds the longest are the Green Gage Plums and choice Pears.

Extension-trained Trees.—In the case of young wall trees which have had the unpruned growths of last year bent down towards the ground, and secured to the wall in that position, in order to cause all the wood-buds on the individual shoots to push into growth, as advised in a previous Calendar, it will be necessary to draw the nails and spread out the branches evenly over the space allotted to each tree, distributing the young shoots over the intervening spaces, and securing them in position with nails and shreds, or raffia where the walls are wired. Pinch out or rub off surplus buds at the same time. Should any of these young growths be extra strong, pinch out the points, so as to promote a balance of growth.

Watering Wall-trees at the Roots.—Apricot and Peach-trees, and, indeed, all trees on walls having south, west, and east aspects, should receive another good watering at the roots, the soil being first pointed over with a digging-fork. It is much better to give a few thorough applications of water at the roots than to give a dozen surface waters. If directions as to applying a mulch of short dung over the roots of the trees have not yet been carried out, no time should be lost before doing so.

THE KITCHEN GARDEN.

By W. POPE, Gardener, Highclere Castle, Newbury.

Asparagus from Seed and Transplanted.—Where Asparagus has to be raised in quantity yearly in the usual manner in heated pits and hot-bed frames, some plants should be raised from seed each year. The present is the best time to sow. The seed should be scattered very thinly in shallow drills drawn 1 foot apart; the plants so raised will not require to be transplanted or thinned, and with liberal treatment will afford some useful heads the third year. If the plants are to be grown in old-fashioned beds, the seeds should be dropped in patches of two or three together, allowing 1 foot between the patches, three rows of patches going to a bed. For ordinary permanent plantations the seed may be sown on the flat in rows from 2 to 3 ft. apart, the vacant land between being utilised for a year or two for growing salad, Spinach, dwarf Calf-worm, &c. It is important that the soil for Asparagus be deep, rich, and well-drained. The month of April affords the best time for planting new beds and filling vacancies in old beds and lines. If a showery day be chosen for the job, all the better; and the plants should be from 1 to 3 years old, though older roots may be safely lifted and replanted. Be careful to place the roots straight from the centre and to place the crowns 3 inches deep in the soil. If the weather should be hot and drying soon after planting, a slight mulching of light manure or decayed leaves may be placed over the roots. Established beds of Asparagus will be benefited by a liberal application at this season of liquid-manure; or of guano, salt, and soot, or sulphate of ammonia at the rate of 2 ounces to the square yard. These manures may be applied during showery weather, and repeated once or twice during the next two months.

Broad Beans.—When the plants have reached a height of about 4 inches, mould up the rows as a means of steepling the plants against wind. Seed may be sown of Green Windsor and Beck's Green varieties, for furnishing pods in the months of July and August. A soil that is moderately rich is found to be the best for Broad Beans.

Spinach.—A sowing should be made fortnightly, and repeated at three weekly intervals, so as to ensure a full supply during the season. When the seedlings are large enough to handle do not wait, but thin them to a distance of 5 inches apart. Some defer thinning till the leaves are large enough for use, and then draw out surplus plants as Spinach is wanted; but this is mistaken economy, the leaves never attaining to their full size, and the plants are sure to run prematurely to seed.

Capsicums and Egg-Plants.—Seed may be sown in gentle heat, the seedlings being pricked off singly into small pots when large enough, and grown on in a temperature of 65°, and repotted when necessary. (If the seed may be sown in thimbles or 40's, and not transplanted, and so time be saved. Ed.) If suitably handed-off late in May, both species may be planted at the foot of south or west walls in the following month; when given a favourable season, they will ripen their fruit perfectly. Except, however, on very warm sites, the plants are more satisfactorily grown in pots under glass, being then useful for decorative purposes, more particularly the Capsicums.

Vegetable Marrows and Ridge Cucumbers.—Seed of both may now be sown in warmth, grown on gently near the light in a temperature of 60° to 65°, and hardened off carefully previously to planting them outside about the middle or end of the month of May, with some sort of protection against night cold.

THE FLOWER GARDEN.

By CHARLES HERRIN, Gardener, Droppore, Maidenhead.

Violas.—The supply of these flowers from out of doors will soon be past, and as soon after as possible the plants should be divided and replanted. In the case of most varieties there will be an abundance of runners or young plants already formed for making up the new beds. These beds should be prepared upon a fresh piece of ground, which, when being dug, may be given a liberal supply of thoroughly decomposed manure. If this has been prepared some time previously, so much the better. Put the plants about a foot apart each way, and if the weather be dry, an occasional watering may be required. A mulch of leaf-soil or old mushroom-bed manure is of much assistance. Spare sets at the foot of walls or other sheltered places, having early or late aspects, should also be utilised, in order to forward and prolong the supply as much as possible. Some fine single varieties have been introduced

during the past year or two, including Princess of Wales, a striking variety, with large bright blue flowers, borne on stalks 6 to 8 inches in length. California and Amiral Avellan are others with long stalks and large flowers. Wellisana, sent out some years since by Mr. C. Turner, is also still one of the best, and is rather later in flowering than others.

Lily of the Valley.—The crowns, being just starting into growth, are in a suitable condition for moving. This is necessary if the roots have become matted together, and the growths appear weakly. Sort the crowns over after lifting, and plant the smaller ones by themselves. The new bed should be made upon ground that has been well trenched and manured. Plant the crowns in slanting drills, chopped out with a spade, 3 or 4 inches apart, allowing the same distance in the row. West and north borders are the most suitable ones for Lily of the Valley culture, those on the north aspect affording spikes ten days or more later than those in warmer situations.

Golden Pyrethrum.—Where seedlings of this plant are necessary for edgings or other uses, seeds may be sown thinly in hand-lights, or even on a south border in the open, covering them very slightly with fine soil. The seedlings may be transplanted to the flower-beds early in June.

Tagetes signata pumila is a useful yellow-flowering annual, and forms a fairly good substitute for the *Calceolaria* upon soils of a light, sandy nature. Seeds sown forthwith in boxes, or on a mild hot-bed in frames, will be quite early enough to make strong plants by bedding-out time. The seedlings should be pricked off into other boxes or frames, a few inches asunder, as soon as large enough to handle.

General Work.—The pruning of shrubs, roses, &c., should be completed as soon as possible. Afford to Rose-beds a good mulch of rotten manure, and if its appearance on the surface is thought unsightly, cover with a small portion of soil. In light soils, where the Rose-borders have been forked over, to cover manure or small weeds, it will be advisable to trample the soil quite firm round the plants before the mulching of manure is applied. *Jasminum nudiflorum* having passed out of bloom, should receive the necessary pruning and thinning before new growth commences.

PLANTS UNDER GLASS.

By G. H. MACVOCK, Gardener, Luton Ho Park, Luton.

Violas.—The time has arrived when the plants may be divided for increase, whether for frame or other culture. A method which is very suitable is to select three of the strongest runners from a plant and place them in a cutting-box, or in rows in a pit or cold frame within 2 inches of the glass, and keep them regularly syringed till rooted, which will be in about a fortnight. On the appearance of roots, air must be admitted to the frame, gradually increasing the amount, till by the end of April the plants will be in a fit state to be planted out in their summer quarters. Other growers choose young side-growth with roots, and plant these out without further preparation. The aspect selected for the summer, opposing the plants are to be grown in frames for the production of winter flowers, is one that is half shady, and where the soil is in good heart, or can be made so with a heavy dressing of leaf-soil or thoroughly rotted dung. If the soil is not naturally tenacious, it should be dressed with heavy loam in addition to the manure, which will enable each to be lifted in the autumn with a compact ball of roots and mould, that need not be reduced in size before planting. If space be no object, plant the rooted runner or rooted offsets 18 inches apart each way, although 1 foot by 1 foot will suffice; so much being necessary to allow a hoe to pass in between them. As the season advances, the Violas will grow fast if the soil be kept moist, and they are dewed over after warm days; and a weekly examination should be made for runners, which should be nipped off when quite young. By keeping the soil moist, and the leaves wetted with the garden engine, red-spider, which is very inimical to the Violet, will be wholly prevented from infesting the foliage, or its ravages would be greatly checked. Marie Louise is still one of the best varieties. Neapolitan and New York form a succession to this one. A good single white is Rawson's, the flower having plenty of much substance. The Czar and California are single-flowered varieties; *Comte de Brazza* is a double one, and white.

Work in the Plant-houses.—Colours may be increased by placing cuttings to the required number singly in thimbles, and if large plants are required, these should

be repotted as soon as they are well rooted. A few young plants should always be kept in 3-inch flower-pots for dinner-table decoration, &c. Roses growing in pots, and others potted out, must not be allowed to get over-run with aphides, or remain infested with the Rose-maggot, nor the beds lack water. If mildew should attack the leaves and shoots, apply dust daily with it. Zonal and Ivy-leaved Pelargoniums for flowering in the autumn should be potted forthwith, and placed on inverted pots in an intermediate-house or pit. Lachenalia which are gone out of flower should be afforded less water, but enough to prevent premature decay of the leaves; only after the leaves are decayed should water be withheld altogether, and the pots stored in a cool-house.

Hydrangea hortensis.—Any plants which have been standing in cold frames since the autumn, if wanted to flower early, should be placed in the greenhouse, previously washing the pots, and affording a light dressing of artificial manure to such of them as were not repotted last year. Large specimens should be staked and tied anew, unshapely branches being removed. New shoots with buds and green cuttings, which, by inserting them singly in 60° F., will strike in gentle bottom-heat under bell-glasses. A few cuttings should be struck annually, so as to keep up the stock of plants, and most of aged plants being thrown away.

Chrysanthemums.—If green-fly be present on these plants, dust the infested shoots lightly with tobacco-powder, doing this late in the evening, and syringing it off early next morning. Do not let the plants get pot-bound, but shift into 6-inch pots as soon as the roots have run all through the soil, using well-drained, clean pots, and keeping the plants close for a few days; then gradually affording air in larger quantities, and in a few weeks remove the lights, but do not shut the present protect from rain off, but do not coddle the plants. The soil to be used in the final re-potting should be mixed, and placed in a heap in an open shed in readiness for use.

THE ORCHID HOUSES.

By W. H. WARR, *Orchid Grower*, Burford, Dorset.

Cataseum, *Cycnoches*, and *Mormodes*, are very curious and interesting plants. Unfortunately, the majority of cultivators have found it very difficult to keep them in a thriving condition. They grow and bloom satisfactorily for possibly some years, and then in the absence of any apparent reason, they gradually deteriorate. This is mainly attributable to insufficiency of bright sunshine during the autumn to thoroughly mature to nearly ripe pseudo-bulbs. Without sunshine during that period it is impracticable to afford them the amount of water necessary to enable them to keep plump during their long period of rest. The majority of these plants are now commencing to grow, and immediately the young growths are seen pushing from the base of the pseudo-bulbs, turn the plants out of the old compost, and cutting away all dead roots and decayed parts. Eradicate every vestige of scale or mealy-bug before the plants are repotted, or they may give trouble throughout the growing season. I find that basket-cultivation is preferable to that in pots or pans, as the aerial roots delight in pushing their way out around the basket into the moist atmosphere. Select shallow Teak-wood baskets with copper-wire handles about 12 inches in length, so as to bring the plants well up to the roof-glass. Place a few flat pieces of crock over the bottom of the baskets, and use a compost of fibrous-peat and sphagnum-moss in equal parts, with a moderate quantity of small crocks intermixed with it, and press the material around the plants with moderate firmness. *Cataseum parvum*, *C. Christyana*, *C. Russellianum*, *C. hirsutum*, *C. b. spinosum*, *C. tabulare*, *C. longifolium*, *C. scabra*, *C. scacatum*, *C. tritricatum*, *C. Bangrothii*, and its several distinct varieties should be suspended to the roof on the east side of the East Indian or Dendrobium-house; also, *Cycnoches chlorochilum*, *C. peruvianum*, *C. pentadactylum*, *C. Ezeronianum*, and *C. versicolor*. The varieties of *Mormodes*, as *M. Rolfei*, *M. parvum*, *M. p. unicolor*, *M. luxatum*, *M. l. abnorme*, *M. buccinatorum* should be placed in the warmest and lightest part of the Cattleya house. For the next few weeks, after re-potting the plants, water must be afforded sparingly; very little indeed is necessary until the growths are well advanced, and the roots have obtained a firm hold of the new compost. When the plants are re-established, and growing strongly, they will need an abundance. One of the main conditions of success is to grow these

deciduous plants on as quickly as possible, so that they will finish up early in the season, and therefore have the full benefit of the late summer and early autumn sunshine to consolidate and ripen the pseudo-bulbs.

Habenaria.—Now that the cultivation of *Habenaria mutabilis*, *H. carnea*, and its pure white variety, *nivosa*, has become more generally understood, no amateur who has the necessary degree of warmth, need hesitate to cultivate these beautiful Orchids. They are pretty decorative plants, and the flowers are useful for cutting purposes. The new growths which are now appearing start away in a similar manner to those of the *Cataseum*. Immediately the shoots are seen pushing up through the soil, the tubers should be turned out of their pots, carefully separated, and re-potted singly into pots as small as possible, giving perfect drainage. Place the tuber in the centre of the pot, keeping the crown just below the rim, then fill the space around the tuber with clean crocks to within an inch of the top, so that when repotted a part of the tuber will be in the crocks, and the other part in the compost. Over the drainage place a thin layer of sphagnum-moss, and fill up with the following compost, just covering the top of the tuber:—One-half fibrous peat and loam, and one-half chopped moss, a moderate quantity of finely-broken crocks, and coarse silver-sand, mixing the whole together, and potting moderately firm. It is not necessary to shift the plants into pots of larger dimensions after the first potting. When the plants have been potted, place them on the shady side of the warm-stove or East Indian-house, as near to the roof-glass as possible. Water must be given sparingly at first, merely sprinkling the surface of the soil occasionally with a fine rose-water can. As soon as active growth commences and the plants are rooting freely, gradually supply them with an increased quantity, and when in vigorous growth, they may be given an almost unlimited quantity. During bright sunshine some shade must be afforded them, and it will be very beneficial to them to well syringe the undersides of the foliage occasionally, which not only encourages strong healthy growth, but prevents insect pests disgracing the delicate foliage. *Habenaria Sionnæ* may also be repotted now, and placed in a shady part of the Cattleya-house; it is a similar case of treatment. Plants of *H. rhodochila* that were repotted early in the year should now be closely watched for small yellow-thrips and red-spider.

FRUITS UNDER GLASS.

By F. HARRIS, *Gardener*, Eastnor Castle, Leicestershire.

Peaches and Nectarines.—The fruits on trees in the early house, which were started in December, having passed the stoning period may be pushed on a little faster; the temperature at night being raised to 60°, and the house closed early, taking care however that the temperature does not afterwards exceed 55°. The syringe may be used freely twice a day, which is the best preventative of red spider, occasionally damping down with manure-water, and putting some of it in the evaporating-pans. Afford good applications of tepid-water at the root; and if the trees are carrying heavy crops of fruit, manure-water will be required in addition. Keep the shoots for next year's bearing tied in; avoid overcrowding; stop lateral and forejoint shoots at the first joint, and keep the fruits clear of the leaves by putting the latter aside, not by pulling them off. In the case of Nectarines, if the fruits are inclined to rust, morning syringing should be discontinued, this being a chief cause of this disagreeing appearance. If the trees are well syringed at closing time, and the paths, &c., are damped occasionally during the day, the trees can be kept in a healthy condition.

Succession Peach-houses.—These, according to the time the trees have been started, will require the same sort of attention as that afforded the trees in the early house in the matters of disbudding and stopping shoots, thinning the fruits, &c. See previous Calendar for directions as to the manner of carrying out these operations.

Late Houses.—The trees will now be in flower, and should the weather be dull and wet, a small amount of fire-heat may be required, and the candle-hair pencil be used to induce regular fertilisation. If the weather is sunny, neither will be necessary. Houses having no heating apparatus should be shut up early in the afternoon, in order to imbue sand-heat. We are obliged to burn oil-stoves in some of our cold-houses, to prevent the flowers being frozen, as we have had as much as 11° of frost quite recently.

THE APIARY.

By EXPERT.

Artificial Pollen.—If the weather becomes warm, pollen should be freely gathered now, and failing a natural supply, Pea-flour may be given in its stead. For inducing bees to take Pea flour, nothing excels a cold skep from which combs have been cut out. After being warmed at the fire its odour will attract the bees to it very soon, and they will take the flour, scattered on shavings, at a great rate.

Feeding.—Good stocks will be increasing fast in population, and brood-rearing making on, and progress, that when natural pollen can be gathered, the stimulus already acquired will be continued without any care on the part of the bee-keeper. Honey from natural sources will, however, be scarcely obtainable in sufficient quantity for the needs of stocks for weeks to come, and attention must, therefore, be given, even by those who wish to do as little as possible, so that the prosperous condition of breeding-stocks may be continued without a check until the honey harvest opens. Artificial supplies by means of the feeder should also be given in all cases where they are beneficial.

Packing Bees for a Long Journey.—The packing of bees for transit is now-a-days more of a necessity than it was years ago, as bee-culture has become general, and the demand for stocks as well as swarms has in consequence vastly increased. Years ago, when I commenced bee-keeping, I had a good apprenticeship at packing stocks and swarms, and many were the losses at first resulting from my too careful method of packing. Now, the moving of stocks from one apiary to another, near together or far apart, can be carried on without danger, seeing that most stocks are upon combs built upon foundation that has been wired into the frames. Before anyone buys stocks at the present time, I strongly advise the employment of an expert to make a careful examination of them, to see that they are healthy, for with the prevalence of foul broods this is more than ever necessary. By no means have stocks from or near an infected area. I very much regret to see advertisements of stocks by men whose apiaries have been badly affected with disease; and a neighbour tells me he saw a lot rotten with disease in one advertiser's apiary this season. If the stocks, declared to be healthy, are taken from his own or any other apiary in the village, they will be a source of danger to any neighbourhood to which they may be sent. Presuming, however, that the stocks to be removed are healthy, they should be packed in the manner here indicated.

Packing Stocks on Movable Combs.—If the stock is to remain in the hive, nothing need be done to the brood-chamber if on the tiering-plan, and it is full of combs; but if it is a long hive, and the frames do not fill the chamber, the dummy should be nailed close up to the last frame, and the empty space filled with chaff or other material. In either case the bees must be confined to their combs by a piece of perforated zinc being nailed over the entrance, and a sheet of it over the tops of the frames. A lath should also be nailed across the frames to keep them from moving. The lift and the roof may then be replaced; and, to make all secure, a French nail should be driven through the paths to fasten the brood-chamber to the floor-board and the upper parts of the hive to those below them. Finally, a stout cord must be bound round to facilitate lifting and carrying; and, as a last precaution against rough or careless handling, a couple of chaff-rolls, like the well known sand-bags, should be tied under the front and back of the hive. A simple and satisfactory method of moving stocks is to place the frames—say nine—with adhering bees in a box. The holes into which the ends of the top bars rest are either cut out of the wood or a piece of iron, to be placed across the top. The holes must be seven-eighths of an inch full, and six-eighths of an inch open, the latter distance being given because the combs are not all of equal width in every hive as a result of bad spacing, and a little extra room in travelling is an advantage. There should be a space of five-eighths of an inch at least below the frames, and inside the box a piece of wood, half-an-inch, should be nailed across the ends about half-way down. Through this piece of wood drive French nails at long intervals, at points to be marked on the sides of the box, and fix the ends of the top bars above. If they are a trifle wider, there will be a little play for the combs, which are better not kept quite rigid. For ventilation, holes about 9 inches square are made both in the lid and bottom of the box, which, as well as the entrance, are covered with perforated zinc.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, APRIL 13. Royal Horticultural Society's Committee (National Auricula and Primula Society), at Drill Hall.

THURSDAY, APRIL 15.—Linnæan Society.

SALES.

Special Sale of Begonias, Carnations, Dahlias, and Thousands of Hardy Plants from Ware's celebrated Collection, at Protheroe & Morris Rooms.

MONDAY, APRIL 12. Great Clearance Sale of Business Orchids, by order of Mr. J. W. Moore; Orchids in Flower, Stove and Greenhouse Plants, Liliaceæ, &c., at Stevens' Rooms.

Lilies, Palm Seeds, Greenhouse Plants, Begonias, Carnations, &c., at Protheroe & Morris' Rooms.

WEDNESDAY, APRIL 14. English and Foreign Palms, 1000 Roses to name, Ornamental Shrubs, Tender Plants, &c., at Stevens' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—45°.

ACTUAL TEMPERATURES:—

LONDON.—April 7: Max., 59°; Min., 39°.
PROVINCES.—April 7 (6 P.M.): Max., 49°; Valencia,
Min., 40°; Aberdeen.

A SHORT time since, in the village of Arbot-Doy, Kent, was inaugurated what may eventually grow into a pleasant and a profitable custom—one borrowed from the United States, but none the worse on that account. On a particular day the school children participate in the planting of fruit or other trees in commemoration of their country's inauguration. Here it is proposed to do likewise, to fix upon a day, in autumn preferably, and then with due ceremony and rejoicing to plant fruit-trees. Patriotism is to be aroused, the national flag is to be unfurled, the safety of the QUEEN besought, and blessings to be invoked on the Prince of WALES! This is all very idyllic. If it grow spontaneously it will surely succeed, but if it is to be done to order, it will assuredly fail; but again, if it be conducted as a matter of business, it has a very fair chance of success.

In any case it must have a beginning, and what the sequel may be must depend on the plans and on the practice of the promoters, as well as on circumstances. The promoters must start with a clear notion of what they intend to do. There are many courses before them. If they mean to get up a village festival, instil a little patriotism, convey a few useful lessons on planting and the management of trees, they will, no doubt, effect some indirect good; but the benefit as regards the extension of fruit culture, looked at as a business, will be trifling. If they mean, after due trenching and preparation of the soil, to set aside each year some acres for a fruit plantation, with dwarfing stocks and intervening Gooseberry bushes, Black Currants, Raspberry quarters, and perhaps Narcissus, Violets, and Wallflowers in between, well and good; the result will, no doubt, be excellent—if the landlord and the tenant have an agreement satisfactory to both parties, and a good market be within convenient access. But the village-festival part of the business will, we fear, in such case be a little out of place.

Supposing such a ceremonial to be desirable, would it not be well to associate it rather with the gathering in of the harvest, especially if planting is to be done? The Kentish peasantry, and a whole army of denizens of the London slums, find their way in late autumn to the Hop-gardens to pick the fragrant catkins. If the weather be propitious the results are excellent; but if otherwise, the hospitals and dispensaries are for many weeks after overfilled with patients suffering from rheumatism or chest complaints.

The gathering in of the fruit crop is not, as a rule, beyond the powers of the villagers and their children; and here is one point we suggest to those who desire to foster an "arbor-day"—the men might on picking days be instructed in less primitive methods of gathering the fruit than by knocking them down with a broom-handle, or throwing them at random into a basket; and the girls and the boys might easily be taught to handle the fruit carefully, to pick out the bruised and worm-eaten fruit for the benefit of the pigs and fowls, and carefully to select, and with equal care to pack, the finest specimens. Our farmers might well imitate the care with which the Spanish or Canary Island peasants wrap each orange in paper, or in a maize-leaf. Opposite our windows as we write are boxes of Tomatos and Potatos from the Canaries packed with a degree of care and neatness we do not often see in the home productions.

Quantities of English Apples, as we have also the opportunities of seeing, come into the market in such a condition as to be practically unsaleable. It is sheer folly to waste time, labour, and money on sending such samples to market. They fetch nothing. Good, even parcels of fruit of uniform quality, well packed, and sent to market at the right time, may fluctuate in price from various circumstances, but on the average of years they are sure to be profitable.

The idea of teaching boys and girls not to throw Apples about as if they were stones, and of setting them to sort the Apples and pack them, will, of course, raise the objection that the said boys and girls, being boys and girls, will take toll. No doubt they will, but not to any serious extent, and the presentation of a few Apples and a little kindly supervision and tact will reduce loss from this cause to very small proportions.

Another suggestion occurs to us with respect to "Arbor-day," and that is, to plant the sides of the country roads and other waste places with fruit trees. This is successfully done in some parts of Germany, and the practice is gradually spreading. The little kingdom of Wurtemberg derives an annual amount of 1,500,000 francs a year from its fruit-lined roads. In Aleace-Lorraine, as M. BALLET tells us, the trees were planted by the Germans some twenty years ago, and each tree now yields on the average a revenue of 15 to 25 francs, or 150,000 francs a year. In France, too, a few Poplars are often planted by the peasant proprietors at the birth of Marie or Annette, and these Poplars form a valuable *dot* when Marie or Annette think it desirable to establish a home of their own. As to road-side fruit-trees, the plantation would have to be done with great care, and some people will no doubt think that their plantation would constitute a direct encouragement to a breach of the eighth commandment; but it would be easy to plant sorts which, however valuable for the manufacture of cider or of preserves, would not be so

palatable as to ensure a second marauding expedition. The loss from deprivations of this kind in districts remote from towns and railway-stations would be practically infinitesimal, and it is to be hoped that there are not many who would rail at the occasional abstraction of an Apple by a dust-bestrewn traveller. Moreover, the robbery of private plantations would be proportionately lessened.

Even if they were of little use for their fruit, the plantation of such trees would be valuable as affording shade and shelter to pedestrians and cyclists, they would serve as wind-breaks and landmarks, and they would add to the beauties of the country, now often ruthlessly destroyed.

The waste in the case of uncoccupied walls is also something prodigious. It is the exception rather than the rule to see the farm-house and its adjoining buildings, or the labourers' cottages, covered, as they might be, with Apricots, Pears, the finer sorts of Apples, and on the north side Morello Cherries. If "Arbor-day" can be turned to account in stopping this culpable waste of means and opportunities, we shall have cause to thank the foresight of those who initiated so beneficent a custom.

As we have said, it is desirable to have a clear idea of what we want to do before commencing operations; and the Eynsford folk here, it appears, the intention of extending cider-making in Kent. We remember when cider was made—perhaps it still is in Kent—along the Sussex border, but our recollections of the beverage are not pleasant ones! The manufacture of cider is a delicate and difficult process; it cannot be learnt by novices in a season, and hence the question arises whether it would not be well to grow the Apples in Kent, and send them to Herefordshire, Devonshire, Somersetshire, or Norfolk, where the cider manufacture is better understood than it is in Kent. But that is a detail that the experimenters must work out for themselves. The drying of Apples—illustrations of which were shown at Chiswick a few years ago, and which formed the subject of an address by Mr. BADGER before the Society of Arts—is also a matter to be thought of by the Arbor-day planters. A man who plants a tree properly—we do not say one who "sticks in" a tree—is a public benefactor. If he can combine his beneficence with a village festival and so lighten the dulness of village life, while, at the same time evoking a spirit of patriotism, he will be a threefold benefactor.

SPRING-FLOWERING PLANTS AT CROYDON.—

The greenhouse containing the plants illustrated by fig. 78 is in the gardens of F. LLOYD, Esq., Coombe House, and at the time our photograph was taken it offered a very gay aspect. The well-flowered Cyclamen plants were in 5-inch pots, and there are sixteen plants represented in the picture. There is a batch of excellent Chinese Primroses on the left-hand side of the figure, but they cannot be seen distinctly. The Cinerarias are very good, and are suitably arranged with Azaleas, Deutzias, Begonias, and a few ornamental foliage plants. A good specimen of *Dendrobium Fierdigi* may be discovered in a suspended basket at the extremity of the house. Several plants of *D. crassinode*, and a *Phalenopsis*, are also suspended in baskets. Had there been a freer use made of basket plants, including *Lachenalias*, of which we notice there are included several good examples, it would have had the effect of improving the appearance of the roof of the house. Mr. M. E. MILLS is the gardener at Coombe House, and to him are we indebted for the photograph.

FIG. 78.—SPRING-PLANTING PLANTS AT COBBE HOUSE GARDENS, TRIMDON, STRAHLA. (SEE P. 206.)

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the fruit and floral committees will be held on Tuesday, April 13, in the Drill Hall, James Street, Westminster, in connection with which the National Arbutus and Primula Society will hold their annual show from 1 to 5 P.M. At 3 o'clock a lecture on "Artificial Manures" will be given by Mr. J. J. WILLES.

LINNEAN SOCIETY.—On the occasion of the evening meeting, to be held on Thursday, April 15, 1897, at 8 P.M., papers will be read:—1, "On some New Irish Crustacea," by Mr. A. O. WALKER, F.L.S.; 2, "On *Onidism* from Singapore," by Messrs. W. and G. S. WEST. There will be exhibited a number of plants collected during two years' residence in Franz Josef Land, by Mr. H. FISHER.

HORTICULTURAL CLUB.—The usual monthly dinner and *conversations* will take place on Tuesday, April 13, at 6 P.M. A paper will be read on the "Flower Gardens of Victoria," by Dr. ERNEST D'OMBRIAN, of Melbourne.

CRYSTAL PALACE FRUIT SHOW.—The prize schedule for this show will be issued in a week or ten days' time by the Royal Horticultural Society, and will contain an authoritative list of dessert and cooking Apples, and Pears and Plums. Post free, one penny. Donations towards the prize fund will be gratefully received by the Society.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—Mr. ARTHUR W. SUTTON, of Messrs. SUTTON & SONS, Reading, has contributed the sum of £100 to the "Victorian Era Fund," which is being raised by this Institution to commemorate the Diamond Jubilee.

TORQUAY DISTRICT GARDENERS' ASSOCIATION.—We learn from the fifth annual report and balance-sheet for 1896-7 that this Society has made steady progress, the number of members has slightly increased, excepting honorary members, who are rather fewer than in previous years. The financial condition of the Society is good, a small balance being in the hands of the Treasurer. The fifth annual summer outing will take place as usual towards the end of July.

ISLE OF WIGHT.—The monthly meeting of the Isle of Wight Horticultural Improvement Association was held on Saturday, April 3, at Newport. In the afternoon and evening there was an exhibition of Daffodils, Tulips, and other spring flowers staged by Messrs. P. BARR & SONS, London; T. WARE & SONS, Tottenham; E. CAVE & SONS, Newport, I.W.

CINERARIA BLOOMS are sent us by Messrs. CARTER & Co., High Holborn. These flowers represent a valuable strain; they are of large size, and possess varied, distinct, and bright colouring. A large quantity of plants in bloom may now be seen at Messrs. CARTERS' nursery at Forest Hill, S.E.

THE ROYAL HORTICULTURAL SOCIETY OF IRELAND held a spring show on the 1st inst. in the Royal University Buildings. The display was of moderate extent, and consisted principally of Narcissus.

THE ROYAL SCHOOL OF HORTICULTURE AT POTSDAM.—The Royal Horticultural School at Potsdam, opened in 1824 by request of LENNE, the Director of the Royal Gardens, is one of the oldest and most celebrated institutes for the education of the gardener, and is able to look back on an existence of almost seventy-five years. It is the intention of the former pupils, friends of the Institution, and members of the craft to have a jubilee in 1899 in celebration of the opening of the institute; and numerous professors, head gardeners, nurserymen, landscape gardeners, and others, in response to a circular sent out by Herr WALTER, Royal Court Garden Director, and Herr T. ECHTERMEYER, the Inspector of the Royal Horticultural School, Potsdam, have signified their willingness to form an executive committee for the intended jubilee, and it may be taken for granted that nothing will be lacking to make it in every respect

a success. Already large sums of money have come to hand for the "Travelling Fund." This fund is intended to afford assistance to needy craftsmen who are certified to be deserving persons, but who lack the means to take journeys for intellectual improvement; as likewise for furnishing funds for the festivities. The Executive Committee, and that of the Great General Horticultural Exhibition, meet on Thursday, April 29, at the Hotel Imperial, Unter den Linden, Berlin, in reference to the celebration of the seventy-fifth year's jubilee of the *Vereins der Beförderer des Gartenbaus in den Preussischen Staaten*; and variously to settle the order of the festivities, and what further steps it will be necessary to take.

TRENTHAM AND HANFORD HORTICULTURAL SOCIETY.—The ninth annual exhibition of this Society has been arranged to be held on July 22 next in the Tretham Gardens, by permission of His Grace the Duke of SUTHERLAND, who is also President. In the schedule just to hand there are upwards of 100 competitions, composed of "Open to all" classes, others for gardeners, single-handed gardeners, local exhibitors, and cottagers. There will probably be considerable competition in the open class for a group of plants, and in the fruit classes. One of the principal of the last-named section is a class for a "decorated table of ripe fruit." We hope that nothing will prevent the show from being held this season, as was the case last year.

"FAVOURITE FLOWERS OF GARDEN AND GREENHOUSE."—This publication, to which we have previously had occasion to refer, is an excellent one for the amateur who desires to know something about the plants he cultivates. The text is clear and to the point; the illustrations, which are true to Nature, contain many details not ordinarily found in such publications, and err on the side of reduction rather than of exaggeration. Messrs. F. WARNE & Co., Bedford Street, Strand, are the publishers.

PLANES and WILLOWS.—"By the waters of Babylon," says the Psalmist, "we sat down and wept." Some of the riverside residents at Kingston and Hampton Wick seem disposed just now to do the same by the water of the Thames. They lament the gradual disappearance of the long line of common and very old pollarded Willows which ran along the side of the river by the margin of the Kingston town Canbury Gardens. The Willows are so old, and in such condition of decay, that if headed back they never braced again; and many not headed have nearly all the long branches dead. There can be no doubt but that this gradual decay was hastened some years since when the promenade by the riverside was first made, owing to the foundation, some 18 to 20 inches in depth, consisting of town-ash or refuse, which partially buried the stems, and largely poisoned the roots. In some parts of the gardens where the swampy ground was raised by this material 2 or 3 feet, old Willows have been killed wholesale. Now nothing can save those on the riverside, and as Plane trees planted on one portion, where there were no Willows, several years since, have done remarkably well, the corporation are planting other Planes between the old Willows, and an outcry has in consequence been raised, the planting of other Willows being demanded. The reply is, that owing to the presence of the ashes in the foundation, the Willows will not thrive, but the Planes will. Birch, a charming tree in or out of leaf, has been suggested as a substitute. The old Willows are not of the graceful weeping order, and many of them are now most artistically ugly.

THE FORMAL STYLE OF GARDENING.—The *Builder* of March 27 contains a view of Versailles at the time when men wore cocked hats and periwigs. The gardens as shown are most elaborate, consisting of tall hedges enclosing temples, theatres, fountains, triumphal arches, and other specimens of the topiary art. The general effect is not so ridiculous as might be supposed, because it is in harmony as to form with the Palace, but a temple cut out of Yew or Laurel is a gross perversion and misapplication of material. If the hedges and clipped trees were all removed and

turf laid down, how vastly the Palace would be improved!

THE ROYAL COMMISSION appointed to visit the West Indies and to advise upon the steps desirable to be adopted in view of the decreasing profits from Sugar culture, has visited several of the islands, Trinidad, Jamaica, &c., and is likely to return to this country in May. Dr. MORRIS, whose experience in such matters is so extensive, forms part of the Commission. From the time of Sir WILLIAM HOOKER, who inaugurated the Colonial department, if we may be allowed to call it so, great attention has been paid at Kew to colonial requirements, and now the visit of the Assistant-Director cannot fail to be of service.

SUMMARY OF A METEOROLOGICAL JOURNAL.—The observations tabulated in this sheet were taken by Mr. LEESON PRINCE, at his Observatory, Crowborough Hill, Sussex, during 1896. As a brief epitome of the weather, as chronicled at this and neighbouring stations, we note that the spring months of the year were somewhat mild; drought being experienced (except during March) to an extent unprecedented for several years so early a season. The remaining months were, on the whole, wet, with the exception of some brilliant weather in July. Judging from records taken in other parts of England, the unusual drought and subsequent rainfall were very generally experienced.

FERN HYBRIDS.—At a recent meeting of the Zoological-Botanical Society of Vienna, Dr. M. V. ECHENSOEDER showed hybrids between *Asplenium trichomanes* and *A. septentrionale* found in Tirol.

ROSE SHOW FIXTURES FOR 1897.—June 10 (Thursday), Ryde; 18 (Friday), Portsmouth (N.R.S.); 21 (Thursday), Colchester; 29 (Tuesday), Canterbury, Sutton, and Westminster (R.H.S.); July 7 (Wednesday), Hitchin and Tunbridge Wells; 8 (Thursday), Harrow and Woodbridge. The above, together with those given in the *Gardeners' Chronicle* on March 20, reports Mr. ED. MAWLEY, are the only dates definitely fixed that have as yet reached him. He will be glad to insert in the next list, which will be issued early in May, any further fixtures that may be sent to him at "Rosbank," Berkhamstead, Herts.

CURRENTS AND PATRIOTISM.—Rather a strange conjunction this, one might be tempted to say, but that the one affects the other, to-day, must be admitted. In Greece the Currant crop is one of great importance, and the Greeks, fired with patriotism, are to a man in arms against the Turk and in favour of the Cretan. Admitting this, it naturally follows that the growers of "currants, and the men who prepare them for market, as well as those who see to their sale, have had to give up fruit culture and take to the field of war. "Pity 'tis, 'tis true" the Currant crop has to be left to itself—to be matured, sold, and sent away to, amongst other places, the United Kingdom. This means, that unless good peace quickly returns, the year's crop will be valueless, and the gallant little country a loser—a loser where it can least afford to lose—and English matrons will greatly miss the universal favourite, the juvenile consumers of puddings will by this remembrance the year of grace 1897. True, all Currants are not grown in Greece, nor do all puddings contain Currants, but Greek Currants, like Currant puddings, are universal favourites, and the loss will be felt by an extensive, if juvenile, army of consumers. The attention of buyers is being drawn to the possibilities of the Greco-Turkish embargo by circulars emanating from the larger dealers in foreign and colonial fruits, fresh and dry, and it is well, we think, to make a note here of the state of things now existing in Greece as possibly affecting the supply here, and price, of our humble but excellent fruit, the Greek Currant.

"THE WASTED ORCHARDS OF ENGLAND."—The information now collected into the form of a book of convenient size, will be remembered by some readers as having been first issued in the pages of the *Gardeners' Magazine*. Some hard truths are men-

tioned about the ignorance, carelessness, and neglect, which allow plots of land and miles of walls, capable of much improvement, to be practically wasted; and we can only hope that these practices, and the general tendency towards technical education, will in their several ways induce a better state of things in the future. A better understanding between landlord and tenant, and more liberal railway rates, are, of course, primary essentials. The publishers of the pamphlet before us are W. H. & L. COLLINGRIDGE, Aldersgate Street, E.C.

"COUNTRY LIFE."—We are pleased to see that this publication maintains, week by week, the degree of excellence which was shown in the first number of it. The illustrations are good and clear, those reproduced from photographs being particularly faithful. The letterpress also deals with just such subjects, and in just such a way as is most likely to find continued favour with all interested in a country life. The accounts of some of the country houses are most attractive. The publishers are Messrs. HENSON & HARRIS, Tavistock Street, W.C.

DR. KLATT, of Hamburg, died on March 3. He was best known in this country for his work on the Iridaceae.

THE D. THOMSON TESTIMONIAL.—We have received the following note from Mr. A. HENDERSON, of Thoresby Gardens:—"The subscription list for Mr. THOMSON'S testimonial will close on May 1, and it is hoped all who intend to join will send in their subscriptions by the above date."

FIFTY YEARS IN HER MAJESTY'S GARDEN.—CHARLES MARR, an employe in the Royal Gardens at Frogmore, completed his fiftieth year of service last week, and he was presented with an illuminated address of congratulation and a purse of gold, the subscribers towards which included members of the Royal Family. Owing to the sudden decease recently of Mrs. MARR, the presentation was made privately.

THE BULBS IN THE LONDON PARKS are now making a considerable display, and are worthy of a visit. Unfortunately, the weather has recently been very ungenial to them and to plants generally. In Hyde Park, as is usual, the principal display is made in the beds skirting Park Lane. Upon the whole, we think the Hyacinths are stronger and better than the Narcissus, with a few exceptions. A bed of *N. Sir Watkin* is very fine, with a carpet of *Scilla sibirica*. *Dielytra spectabilis* in beds carpeted with double white, and in another case double red Daisies, will look pretty soon. In some beds there are Hyacinths and Narcissus mixed, but in general the effect is not good, as the flowers of both species are in most instances about the same height. If the Narcissus had been stronger, and thrown their flowers an inch or two beyond those of the Hyacinths, a better effect would have resulted. Either species, with a suitable carpet, however, is preferable. Some of the combinations were N. Horsfieldi with H. General Havelock, N. maximus with H. Lord Derby, N. rugulosus with H. Sir H. Berkeley, N. Golden Spur with H. Czar Peter, N. rugulosus with H. Czar Peter, and a border of H. Van der Hoop, N. rugulosus with H. Mont Blanc (white) and H. Charles Dickens (blue). This bed had a very good effect. One of the best examples of such mixed beds in the Hyde Park is one composed of N. princeps, H. Priestley (pale blue), and H. Van der Hoop as a border. Hyacinth Queen of Hyacinths was bordered with H. Mirandolina (white), but the border was rather earlier and taller than those in the centre of the bed. Another bed containing H. Fabiola, and a similar border to that in the previous bed, was much better. Beds of Hyacinths alone in some cases were very good, and had a distinct effect, such as Duke of Wellington, Regulus, and Couronne de Cello; the last-named pale blue variety is very pretty. Narcissus Sir Watkin by itself, in several instances, is commendable. The Polyanthus, Anemones, Wallflowers, Auriculas, and Tulips will be about to flower when these notes are published. In Regent's Park the display is near to Great Portland Street Railway Station, where the spring and

summer displays have been made for years past. The mixing of varieties of Hyacinths in large beds is generally practised here, and by making the surface of the beds in gentle slopes, a very desirable relief is obtained. A large bed so planted this season contains H. Robert Steiger, Gertrude, and Grandeur à Merveille, Charles Dickens (dark blue), and Czar Peter were grouped in another instance, and Gigantea with Czar Peter. Gigantea, Czar Peter, and Charles Dickens together create a very fine effect. The beds of Narcissus are looking well, one very large one contains Emperor; others are planted with Empress, Horsfield, Sir Watkin, and such popular kinds. Amongst the Narcissus are dotted Wallflowers and Primroses, in order to prolong the display as far as possible until the summer bedding plants can be put out. The beds of Tulips will not be in bloom for some days yet. Although the beds contain the best-grown bulbs of all kinds, there are multitudes of Hyacinths, Tulips, Narcissus, Scillas, Muscaris, &c., in glades, under trees, and upon grassy slopes. They present such a beautiful picture that one might be pardoned for preferring it to that of the beds. The old bulbs that have become rather weak, are utilised for this purpose, and the visitor is bound to admit that they have been planted in positions selected with care and taste. The Narcissus, and in less measure the Tulips also, acquire vigour whilst growing in the grass; but not so the Hyacinths, which seem unable to maintain the vigour they possess when put out. The whole of the bulbs under grass in this park offer a lesson to many a gardener, and a magnificent sight to all who see them.

THE WEATHER.—After the abnormally wet March, April has set in with severity. In Scotland the snow is lying on the hills down to about 500 feet, and nearly every day there has been a fall of an inch or more, but it quickly melted. At night the frost has ranged from 8°—12° for more than a week. A correspondent from the Kidderminster reports frost in that neighbourhood to the extent of 11 on Tuesday last.

IMPORTATIONS OF FRUIT.—In the *Journal of the Board of Agriculture* for March are some figures which should make our distressed agriculturists ask themselves whether their low estate is not, in a measure, their own fault. We append only the figures relating to fruits, &c., which can easily be grown in this country in much larger quantities than at present. "Amongst imports of fruit in 1896, the supply of Apples seems to have been nearly doubled, as compared with 1895, and the total considerably exceeds the arrivals of 1894, when close upon five millions of bushels were imported. The average value dropped to 5s. 1d. per bushel, against 5s. 10d. in the preceding year." The quantities of Apples imported in 1896 is stated to have been 6,177,192 bushels of the value of £1,582,471; Cherries, 96,047 bushels of the value of £105,511; Plums, 540,246 bushels of the value of £241,782; Onions, 6,085,505 cwt. of the value of £681,879.

CAPE FRUIT.—Since the arrival of the *Tartar* from the Cape—reported in an earlier issue—other steamers have reached this country with quantities of Grapes, &c. By the *Goth*, 611 boxes of white Grapes, and 41 boxes of red ones, and 9 boxes of Pears. The *Norham Castle* brought 55 boxes of red Grapes, 497 boxes of white Grapes, and 235 boxes of red Grapes. It seems a great pity that so large a proportion has been allowed to get spoiled. Assuming that the packing was at fault, it might be well to repeat the experiment tried some six years ago, when a London salesman, well accustomed to the work, went out to the Cape with a couple of expert assistants, taking a quantity of cork-dust and shavings with them; these "packers" instructed the South Africans in the art, and the resulting consignments arrived in London in fine condition, and brought high prices. Mr. MOLLENO, of the Donald Currie Company, was highly satisfied with the experiment, the growing of fruits at the Cape for the English market having been started and fostered by that gentleman and his company; and it is to be hoped that he may

again be induced to place himself in the van of the Cape cultivators, and so restore confidence in those who have to deal with such valuable wares. Since the above has been in type, two more steamers have arrived from the Cape with Grapes and some Pears. The first on the record is the *Moore*, and she brought over 555 boxes of white Grapes, 50 of black, 90 of red, and 90 boxes of Pears. The reporter adds to this:—"Nearly all these consignments turned out in poor condition. A few boxes of red Grapes turned out in good condition, and realised fair prices." The second ship was the *Lisimore Castle*, and her fruit cargo consisted of 209 boxes of white Grapes, 86 black, and 61 red. The note appended to this reads:—"With the exception of a few boxes of black Grapes, all this consignment turned out in poor condition." *Verb. sap.*

APPLES FROM THE ANTIPODES.—The officials of the P. & O. Steamship Company courteously send us the following:—"We have a wire from Melbourne of the following shipment of fruit, viz., per Orient Co.'s ship *Ormus*, 23,000 boxes; per P. & O. *Acadia*, due here about May 2, 10,000 boxes."

PUBLICATIONS RECEIVED.—From the U. S. Department of Agriculture, *Farmers' Bulletin*, No. 15, *Some Insects Injurious to Stored Grain*, by F. H. CHITTENDEN, and (Division of Entomology) *Some Miscellaneous Results of the Work of the Division*; this is a record of patience followed by satisfactory results.—*Annual Report of the Secretary for Agriculture*, Nova Scotia.—From the Essex County Council, *Report and Handbook of the Technical Instruction Council for the Session, 1895-6*. This is a satisfactory report of instruction given in various centres in such subjects as geometry and mathematics, magnetism and electricity, chemistry, physiology, botany, agriculture, and various branches of art. Continuation schools are opened in connection with the ordinary studies, and languages, horticulture, navigation, dairy-work, and coekery, are but a few of the diverse subjects undertaken. The addition of a county school of horticulture to the county laboratory has proved exceedingly successful, and there is much competition for the courses of instruction thereto. From Kolozsar, Hungary, the Director of the University Botanic Garden (Dr. Gy. DE ISTVANFFI), sends a *List of Seeds Offered for Exchange*, which will interest the managers of similar establishments.

BOOK NOTICE.

FIRST RECORDS OF BRITISH FLOWERING PLANTS.

This is in itself a record, and was published originally in the *Journal of Botany*, by Mr. W. A. Clarke. The written record does not go very far back—not further than 1558 (William Turner)—so that from an archeological point of view, the interest is not great, as the reader feels that the plant must have been in the country so many ages before the date cited. It might have been well to have inserted as an appendix the names given in the *Epinal Glossary* as cited by Canon Illicombe in our columns on November 3, 1888, and which dates back to the eighth century. That the record before us is no mere dry list of names and dates may be seen from the following extract, which may also serve to show the general nature of the work, which we may add is published by West, Newman & Co., Hatton Garden:—

"*Urtica pilulifera*, L. Sp. pl. 983 (1753), 1640, Hath been found naturally growing time out of mind, both at the towne of Lidde by Romney, and in the streets of the towne of Romney in Kent, where it is recorded Julius Cesar landed with his soldiers, and there abode for a certaine time, which it is likely was by them called Romania and (*sic*) corruptly therefrom Romney or Romny, and for the growing of it in that place, it is reported that the soldiers brought some of the seeds and sowed it there for their use, to rubbe and chafe their limbes, when through extreme cold they should be stiffe and benumbed; being told before they came from

home, that the climate of Brittain was so extreme cold that it was not to be endured without some friction or rubbing, to warm their bloods, and to stir up natural heat, from which time it is thought it hath continued there, rising yearly of its own sowing.' *Park. Theatr.* 441."

HOME CORRESPONDENCE.

NARCISSSUS CULTURE.—I have read with much interest the paper contributed by Mr. Burbidge to the Birmingham Gardeners' Mutual Improvement Society on "Bulb Culture in England." In common with many other people, I have often wondered whether it was not possible to grow all these beautiful flowers from seed, or increase the stock by other means of propagation. Unfortunately, the literature and information on the subject seems to be somewhat scarce, and also beyond the means of people of my class, viz., working-men and allotment-holders. I am sure, if you could induce Mr. Burbidge, Mr. Egleheart, or any of the great specialists in bulb-culture, or would yourselves give us a few brief articles of the process on either by seed or otherwise of the Hyacinth, Tulip, Narcissus, &c., they would be appreciated by hundreds of small holders, who, like myself, would like to grow them. I grow a few hundreds of the cheaper sorts for decorative and garden purposes, and last year tried a few Dutch roots of the late Tulips—self, hybridous, and bizarres, with which I was so pleased that I selected seed from the choicest flowers to increase, and if possible, improve the stock. The difficulty with me is to know what lines to follow for improvement, if any is possible, time taken to hardy as the allied species. The flower of *Fosteriana* is remarkable for its two characteristic colors, the whole upper part being lemon-yellow, with a more or less conspicuous deep yellow crest; whereas, the turned-down segments or falls are of a deep violet blue. The bulb is very tender, and the roots are thin instead of fleshy, like those of *Iris alata* and other members of the *Juno* group. It is, no doubt, a precious and curious species, but it is too scarce and too troublesome in its requirements to become a general favorite. A coloured plate may be found in the *Edwards'* P. 2715, and reference is also made to it by Professor Foster in his excellent pamphlet on *Bulbous Irises*, pp. 44 and 82. The first publication was made by Dr. Aitchison, who discovered it in Afghanistan, at an altitude of about 4000 feet, and described it, in co-operation with Mr. Baker, in the *Transactions of the Linnean Society*, 2nd ser., Botany III., 114. *Ernst H. Kretzger*.

THE EUCHARIS MITE.—About two years ago, several pots of *Eucharis grandiflora* became infested with the mite here, and there being every probability of the stock becoming affected, I found that unless means were taken to get rid of the pest, the whole lot would have to be thrown away; one-half were treated in the manner I described in the *Gardeners' Chronicle* about twelve months since, and being so well satisfied with the result of that method, the second lot came in for the same treatment, that of cutting away the decayed parts of the bulbs, afterwards washing the bulbs in a solution of lemon-oil, and now the whole stock is in a flourishing condition, without any indication of the mite being present (I pulled out a bulb from among the others in a 6-inch pot, by no means a fair sample, but clearly showing where it was cut with a knife twelve months ago). I have come to the conclusion, by my experience, that the too free use of the watering-pot during the winter months, when the plants are practically at rest, is largely the cause of the plants becoming so affected. The plants here are kept in a temperature of 65° to 70° during the winter months, and 75° to 85° during summer, with shade from bright sunshine, with a very moist atmosphere, and are occasionally lightly syringed overhead, not sufficient to cause water to run down the stem of the leaves into the bulb, thereby keeping them always in a wet condition. *W. H. Sharpe, Highwood Gardens, Rotherham.* [The bulb sent seemed perfectly healthy. We thank you for the careful way in which the specimen was packed. Ed.]

TINNED ASPARAGUS.—Are your readers aware that at the present time tinned Asparagus is being imported into this country from California, and is sold here retail at 1s. per tin, a tin being enough for three or four people? I had it at dinner, and was quite unaware that it was tinned Asparagus until I was told. If the Americans can afford to tin Asparagus, surely this is one of the garden crops which our farmers could get to grow on gently soil, and by arranging to have tin boxes ready, they never need again sacrifice their produce at a low figure. Again, there is no necessity for them to pack Asparagus in such small boxes, because there are many hotels and eating-houses where they would be glad to buy a large tin box; in fact, I see no end to this trade if properly

handled at once. There is one difficulty which no doubt some of your correspondents will be very glad to find a means of getting over, viz., how the Asparagus is treated or prepared in the tins before it is soldered down. Surely we ought to be able to grow Asparagus in this country as well as it is grown in California. *Thos. Christy.* [The sample sent was excellent. Ed.]

WHITE MUSCAT VINE AT GUNNERBURY PARK.—Mr. George Reynolds has carried out a somewhat interesting experiment in one of the portions of the large range of vineries. It is a house of Muscat, consisting of several Vines planted about twenty years ago. The Vine at the west end appears to be a better variety than the others, with fuller and more compact bunches, and Mr. Reynolds brought down one of the rods of this, and laying it along the border, pegged it down at intervals, with the result that it has put forth roots into the border, and throws up eight rods—sufficient to fill the house. With the exception of two of the rods, which spring from a portion of the rod which could not be brought down close to the ground, the remaining six may be said to be nourished by independent roots, as well as by the roots of the mother plant. Mr. Reynolds has always cut the finest bunches from this particular Vine; and this circumstance confirms the opinion, often expressed, that there are "strains" in the cases of particular varieties of Grapes, as in the case of some popular flowers. *R. D.*

IRIS FOSTERIANA.—This very rare species, intermediate between the *Xiphio* and *Juno* groups, flowered in the Bloemhof Nurseries, Haarlem, last week. The bulbs, which were formerly listed annually, have not been removed since the autumn of 1895, and now flower for the first time. They are placed under the frame, but they will probably be as hardy as the allied species. The flower of *Fosteriana* is remarkable for its two characteristic colors, the whole upper part being lemon-yellow, with a more or less conspicuous deep yellow crest; whereas, the turned-down segments or falls are of a deep violet blue. The bulb is very tender, and the roots are thin instead of fleshy, like those of *Iris alata* and other members of the *Juno* group. It is, no doubt, a precious and curious species, but it is too scarce and too troublesome in its requirements to become a general favorite. A coloured plate may be found in the *Edwards'* P. 2715, and reference is also made to it by Professor Foster in his excellent pamphlet on *Bulbous Irises*, pp. 44 and 82. The first publication was made by Dr. Aitchison, who discovered it in Afghanistan, at an altitude of about 4000 feet, and described it, in co-operation with Mr. Baker, in the *Transactions of the Linnean Society*, 2nd ser., Botany III., 114. *Ernst H. Kretzger*.

WOOD-ASHES AND TURF-ASHES. I saw in a recent *Gardeners' Chronicle* an answer about coal-ashes as a manure. Now the wood-ashes require a very little liquid-manure to be mixed with them, as there is plenty of a certain kind of plant-food in them, and if wood-ashes come into contact in quantity with the seed, they do harm and cause them to become sickly and pine away. The ashes of turf are the best absorbers of farmyard drainings, soap-suds, &c., and it is then a better dressing for the land than half the artificial manures sold. The farmers in general let it run into the ditches and waste it. I always water, or spray, my agricultural drainings for mixing with soil, manure, turf-ashes, &c. Now as regards Potatoes, you see I am quite right in my estimation of wood-ashes, and I have always found it so. It affects Tomatoes in the same manner, it never comes from the soil or "the East," as most persons think, and have the idea that if it touches the bine first, it will be sure to run to the root and tubers within three days. *Abel Fairall*.

MONOGRAPH OF ODONTOGLOSSUM CRISPUM.—Two years ago, by the kindness of the editor of the Horticultural Press, I was enabled to procure many forms of this Orchid for the above monograph. I am sorry to say that of late the interest in the work has seemed to die off, and I rarely get fine forms sent me. I hope that 1897 will bring me all the good varieties in so many collections, that I may be able in the autumn to carry out my idea of publishing this work; it will be more than ordinarily interesting now that its subject has absolutely become the Orchid of the world. People may fancy that their varieties are not good enough to be mentioned in a work of the sort—that is not the case. When a plant has one bona-a-variety or distinguishing name, it is useful if be recorded, or there will be a greater and worse confusion than ever existing; already there are

some repetitions of names in the species. I may say that I shall be much obliged for any good Odonotoglossum to record for future writings on other species. *De B. Crasshaw.* [All the varieties, named or unnamed, should be recorded. Ed.]

THE WEATHER IN MARCH.—In looking over my *Gardeners' Chronicle* to-day, I noticed the remarks of H. J. Elwes about the sort of weather experienced in the month of March—an open month, and one favourable to vegetation in general. It was the same in this part of Scotland. Narcissus, &c., are in full bloom; Rhododendrons, Dahpines, and Ribes all in bloom. As on Monday, March 29, we had 6° of frost; on Tuesday, 12°; and 2 inches of snow. The snow soon disappeared on Wednesday, and we had 14° of frost; on Thursday, April 1, 15°; Friday, April 2, 12°; on the 3rd, 12°; the 4th, 12°; the 5th, 11°; and this morning, 9°. It is easy to imagine the damage that has been done, everything that was showing bloom being ruined for this season. Rain has commenced to fall now, so that we hope for more genial weather. *Alex. Crane, Gardener, Bridge of Weir, N.B.*

THE WEATHER IN ABERDEENSHIRE AND THE NORTH OF SCOTLAND.—March of this year will be remembered for its persistent and continued rains. The equinoctial gales raged both before and after the equinox, and the whole of the month was characterized by changeable and unsettled weather. So far as this county is concerned, it may be stated that, as there was a noted deficiency in the rainfall for February—it was 71 per cent. under the average for the month—we might have looked for a certain superabundance in March, and we got it. During the whole month we enjoyed only 63 hours of sunshine, which is not only the lowest figure applicable to any station, but is only half of the average total duration of bright sunshine in the north-east of Scotland for the month of March. There is some satisfaction to be derived from the fact that in the north of Scotland April is, as a rule, decidedly the driest month of the year. *W. Kelly*.

WEATHER LORE.—It was a saying of the gardeners of half a century ago, that just in proportion to the number of fogs in March would be the frosts in May. When I was a schoolboy, I used to ask what was the connection between the two, but never received a satisfactory reply. I should think years have elapsed since there was such an entire absence of fogs in the month of March. Blustering winds have prevailed, as they have doubtless driven the fogs to other lands. The conventional March with angry roar has extended all through the month with a rainfall of probably an almost unprecedented abundance. Soils at all adhesive have been beaten down by the rains to the hardness of a barn floor; and the winds have hardened them still more. But little March planting has been possible, and gardeners are looking forward hopefully for April to bring genial open weather. Will May be destitute of frosts because there were no fogs in March? There is no more anxious time for gardeners than during the last two weeks of the month of May. *R. D.*

FROST AND FRUIT BLOSSOM.—Some trusses of buds of Pear blossom have been sent me from Beckenham, showing that the recent frosts have had laudable effect upon them. The exterior of the buds look as if scorched, and on cutting them open, the stamens were found to be destroyed. This may be a partial visitation only, but if a fair inference can be drawn from accounts received from other parts of the country, the injury done is not at all of a local character. Happily, there is generally an enormous amount of blossom on standard Pear trees, and it is to be hoped that a sufficient number of flower-buds will escape as will afford a good crop of fruit. *R. D.*

THE SPRING OF 1897.—During the thirty years or more that I have been a gardener, I never remember such a March as the one we have just passed through. There has been no east wind, no night-frost worth mentioning, very little dust, very little sunshine, and an extraordinary amount of rain. So far, I am in accord with Mr. Elwes; and while I preface any after remarks by saying that, of course, I know that whatever is, is best, I am sure if I had to choose, I should welcome back again the old familiar east wind and the burning sunshine, and secondly pray that the spring of 1898 might never have a success like itself. Mr. Elwe's very truly says that his remarks apply to a dry, houghy, limestone soil in a very cold, backward district, and may not be equally applicable to more favoured soils and situations. In all

probability that quite explains the difference between his way of looking at things and my own; but I can only say that I never remember a spring which was less like a spring than this, and one which threw us back in such great disappointment. The joyousness of the season has been absolutely unknown; and while the windows of heaven have been open, and rain has been pouring down in torrents, day after day, and week after week, the flowers in my garden have all seemed as if they were quite out of spirits, and some of them looked as though they thought it was not worth while to take the trouble of opening at all. I am not singular in my present ideas. A few days ago I had a letter from Herr Max Leichlin, of Baden-Baden, and he compressed all he had to say about this matter into a line—"the weather here is abominable"—and so, with all due reverence, say I about the present state of things in the Isle of Wight. What puzzles me beyond everything else is this: the swallows have, in some few cases, made their appearance in the island a fortnight sooner than has ever been known before. What can be the reason for that? Is the sky in Africa and elsewhere so overclouded that they have come northwards in search of happier climes?—if so, they must bitterly rue their adventure and had far better go back again to the place from which they came, and await some improvement here. Gardening in the Isle of Wight has almost been at a standstill, not only during the month of March, but all through the winter. I had some cartloads of sand and loam brought into my garden in November last, and I meant to use them at once for the construction of two or three large beds for bulbs, but where this sand and loam were thrown down on the path, there they are now, and there they seem likely to remain so far as appearances go, and this means that from November till now we have never once had three continuous fine days, or the beds would have been made long ago. A very large *Magnolia conspicua*, which is covered with its myriad blossoms and buds, is hardly worth looking at. It is browned all over. It cannot bear to be knocked about in this way, and drenched through and through. *Aucumons* flop about in a thoroughly unhappy way; and *Narcissi*, which do bear up against it all, would look much better under a clear blue sky; and so, I think, it is with most other things. *Fritillarias* hold their own, and *Eranthis*, it is to be admitted, are distinctly better for the absence of cutting frosts; but this is as nothing when compared with the other side of the picture. I tremble for not a few bulbs which I planted a short time ago, and which I fear may rot in the ground; and beyond everything else, I have passed through an agony on account of several hundred *onocycilus* lisses which, if we are to have any fine weather at all, will, I am sure, reward me this year for all my trouble regarding them, but which may give it all up in disgust at the eleventh hour if this sort of thing is to go on. Moreover, how can they be ripened for another year if they are to have no taste of sunshine at all; and what will be the flowers of 1898 be like if maturation in the summer is rendered impossible? I hope I have not written in too querulous a strain. I do not think I was in a complaining mood before Mr. Elwes's words came to hand, and now I quite acknowledge that his explanation is correct. I only say that the plants and bulbs in the Isle of Wight would dearly like to have their accustomed flood of sunshine at this time of the year; that my lisses would clap their hands if only it would come; and I cannot help thinking that I should rejoice in it myself, and I hope that, subject to arrangements of a wider sort, which I do not understand, and with which I have nothing to do, the spring of 1897 may never be repeated here—in fact, I should welcome none less in the future than one like the present, of all the springs we have had during the last thirty years. *H. Ewbank, St. John's, Ryde, April 3.*

FRUIT REGISTER.

APPLE BRANLEY'S SEEDLING.

THIS late-keeping cooking Apple does not appear to be a free fruiting variety, at least, in some districts of the southern counties of England. Seven years ago I planted some bush trees on the Paradise stock, along with several other kinds, in two different gardens, the soil in one being rich and light, and in the other a moderately good but heavy loam; and in neither has this variety been a success. The trees

have made stout firm growth, but do not fruit freely, never having produced in their best year more than a third of a crop, and this after root-pruning has been carefully carried out; therefore I conclude it is a shy bearer, and only adapted for certain localities. My view of the subject was endorsed recently when discussing the merits of this and other Apples with the foreman of a large fruit-tree nursery, his opinion being that "Bramley's was decidedly what may be termed a local Apple," and more suitable for growing in the midland rather than southern counties. As far as its keeping qualities are concerned, my experience is that it is in no way better than Laue's Prince Albert, which is a constant and sure cropping variety of equal, if not superior, cooking quality. *C. H.*

NOTES ON PEARS AT KEDLETON, DERBY.

Being in the vicinity of Derby recently, I had the pleasure of inspecting the splendid collection of Pears on the walls at Kedleston, which, I may add, extend together to a length (at a rough guess) of quite a mile, and form a great feature of the place. Since taking charge of Lord Scarsdale's gardens, Mr. Voss, who previously had been a successful and enthusiastic grower of hardy fruit, as his successes at the Royal Aquarium and Manchester Shows testify, has rejuvenated the majority of the oldest and largest trees, by budding more serviceable varieties on to young shoots springing from the side branches, which had been previously cut back to within 6 inches of the main stem, this being a quicker and to all appearance equally satisfactory method of covering walls than renewing wholesale with young trees. Many, however, were of necessity replaced by young trees, both horizontal and cordon-trained, the clean, bright-looking wood and plump buds showing their vigour and healthiness. Some of the varieties specially noticeable, were Alexander Lambre, which is here a good cropper, and keeps well till January, though Mr. Voss does not consider its flavour so good here as in the south. *Beurré Bachelier* is of good flavour and fine appearance, as also *Bergamot d'Espere*, which is a first-rate keeper. *Beurré Diel* is remarkable for cropping, fine colour, and size, and the fruits keep well. *Easter Beurré* does well, and it furnishes a supply of late Pears. *Brookworth Park* is a heavy cropper, and excellent flavour, compared with others from less favoured localities. *Doyenné du Comice*, considered by Mr. Voss as the best Pear in cultivation, is largely grown, though it does not reach the ideal as foreboded by him at the Royal Aquarium. *Glou Morceau* keeps well, but it is deficient in flavour. *Marie Benoist*, *Marie Louise*, *Marie Louise d'Uccle*, do well, and are good in flavour, as is also the honeyed *Suckle*. *Pitmaston Duchess* I was surprised to hear spoken of in very poor terms; and that *Thompson's* and *Passé Crassane* are poor in flavour, but bear abundantly. *Williams' Bon Chrétien* grows remarkably fine, and the flavour is excellent, I was told; as is also that of *Winter Nells*, which here keeps well into the month of February, but is little esteemed for dessert. *Cæstrina*.

TWO NEW WINTER PEARS.

We learn from the *Jardin*, p. 41, that two varieties of Pears raised by M. Clavier of Tours, are being distributed by M. Pinguet, Guindon. They are named respectively *Beurré Souvenir de Madelain*, and *Beurré H. Martinet*. The first is of middle size, obtuse pyriform, skin deep yellow colour, a little bronzed, and spotted with brown; eye of middle size, and set in a shallow basin. The stalk is short; flesh very fine, whitish, juicy, of a pleasant vinous flavour. A fruit of extra good quality, ripening during January and February. The second forms a strong-growing pyramidal tree, and bears abundantly. The wood is of a reddish-brown, with prominent buds. Fruit is large, conical, and irregular, and greenish-yellow, with a few russet spots; eye of moderate size, is situated in a wide basin, the stalk is short, and the flesh white, very juicy and fine, strongly aromatic, and of excellent quality. It begins to ripen in January, remaining good till the end of March. These varieties, after being tested by the Tours Horticultural Society, received the highest award of the Society.

APPLE YORKSHIRE GREENING.

THIS fairly well-known variety is one of the best culinary Apples I know of at this season. I have grown it for over forty years in three English counties, and nearly always the trees have carried good crops of fruit of first-rate quality. The fruit when thinned out, or not too abundant, is large, and it keeps well till May. I am using the fruits at the present time. It has an agreeable acidity; the rind is of greenish-yellow tint. The tree is a free grower, with a rambling habit, and is not liable to the American blight. *William Smythe, Busing Park Gardens, Alton, Hampshire.*

NURSERY NOTES.

B. S. WILLIAMS & SON.

A CHARACTERISTIC feature of this nursery at Upper Holloway consists in the large number of ornamental or decorative plants to be seen there, including many species for the stove and for the greenhouse. Such are the Palms, the *Aralias*, the *Primulas*, many of the *Cordylines*, *Ferns*, *Araucarias*, *Aspidistras*, *Codiceums*, and numerous other less popular plants. At the present time there is an excellent batch of *Aralias* in one of the houses in splendid growth, and excellent in every way for the embellishment of the dinner-table. They are all well-known plants, but one does not frequently see good batches of them.

The most slender-habited of all is *A. gracillima* (or more properly, *A. Veitchii gracillima*); tender, no doubt, but difficult to excel as a table-plant, providing there is a stock of them, and injury to a specimen through exposure is not of vital moment. Then follows *A. elegantissima*, but little broader in the parts, and when well grown, a distinct and handsome species. *A. Veitchii*, less tender; *A. Chabrierii*, and *A. Regina*, with broader leaves, are all useful in different ways. Unfortunately, it is seldom possible to strike cuttings; and as the stock must be increased by grafting, they are not so common as they would be could they be raised at less expense. There are thousands of Palms, from seedlings with their first leaves to useful specimens of several feet high. Notwithstanding the variety of Palms that now exist, including several very pretty and useful species, the demand even from private gardens is for the common species of *Kentia*, *Cocos*, and *Geonoma*. *Kentias*, especially, are a very popular Palm, and at the present time specimens of a few feet in height are not more than equal to requirements. Were *Geonomas* and *Licualas* as easily cultivated, and *Livistona rotundifolia* and other species as inexpensive as *Kentias*, they would be more frequently seen. *Pinus fabeliformis* and *humilis*, both included in Messrs. Williams' collection, are useful species of easy culture. Several of the *Phœnix* group, including *P. tripicola*, are also extremely decorative plants; but these are not a tithe of the available Palms for conservatory decoration. *Codiceums* (*Crotons*) are given a fair share of space in one or two of the warmer houses, and the collection may be said to embrace a fine selection of varieties, since many of the inferior ones have been weeded out. Growth is just becoming active in these plants. There are pretty plants of *Cordylines* (*Draecenas*), of suitable size for the decoration of the stove or of dwelling-rooms, and some of the newer varieties, such as *Miss Glendinning*, possess handsome-coloured leaves; though the old *D. Cooperi*, *D. Baptisti*, and *D. terminalis* are still desirable plants. After seeing hosts of these and similar decorative species, we notice an unusually large quantity of plants of climbing habit. Whether for pillar, wall, or roof, in hot or cool structures, there need be no difficulty in selecting suitable subjects, for they occupy the greater part of the space in several of the large houses.

Passing to a different class of plants, we noticed a stock of *Rhododendrons*. In one of the cooler houses, where many of the plants are of considerable proportions, such varieties as the following were carrying flowers, *R. asianicum graveolens*, *Countess of Had-*

dington, Denisoni, multidorum, Comet, Forsterianum, Princess Alice, and Lady Alice Fitzwilliam.

The smaller-flowered varieties were well represented in a warmer structure, including such well-known kinds as Queen Victoria, Princess Alexander, Taylori, and T. rubra, Jasminiflorum, Princess Teck, and Princess Royal, one of the best of the whole group, as it is seldom without flowers. Amongst the Indian Azaleas, a new one, called Professor Wolters, struck us as being exceptionally fine. It is rose-coloured, with a very warm blotch on the upper petals; the flowers are of good size, and the margins wavy. In one of the houses a number of pot Vines is being grown, which is, we believe, a new

Obituary.

W. G. HEAD.—It is with sincere regret we have to record the death, in the sixtieth year of his age, of Mr. W. G. Head, the able and respected Superintendent of the Gardens of the Crystal Palace, on Saturday last, after a lingering and extremely painful illness. Mr. Head was about eighteen years in this position, having succeeded Mr. George Thomson. To exhibitors and *habitues* of the Crystal Palace Mr. Head was well known, and much liked, ever obliging to others, never sparing of himself, or seeming to get tired of his somewhat harassing work; and the excellent manner in which the gardening of the

Gardens of the Calcutta Agri-Horticultural Society at Alipore. After a stay of six years in India he returned to England, and was shortly afterwards appointed Garden Superintendent at the Crystal Palace. He was buried at Chiswick on Wednesday last, the 7th inst. The portrait, of which we give a reproduction, was courteously furnished by Messrs. Negretti & Zambra.

RICHARD PFAU.—We regret to have to announce the death of Mr. R. Pfau, at his residence, San José, Costa Rica, on March 14 last. His death was caused by a throat trouble of long standing, which rendered his last days ones of great suffering. Mr. Pfau, who was of Swiss nationality, and well known in connection with Central American Orchids, has for some years been successfully carrying on an important establishment for their culture, and for fruits and other kinds of trees and plants, for sale in Central America. Last year he paid a visit to this country, and succeeded in bringing home a small lot of *Epidendrum Andresii* and of *Miltonia Andresii*, both very difficult species to import. His notes on the climatic peculiarities in which some of the rarest Costa Rica plants are found growing we have published in the *Gardener's Chronicle* on several occasions.

MRS. T. W. BOND.—The many friends of Mr. T. W. Bond, gardener to C. L. N. Ingram, Esq., Elstead House, Godalming, and one of the members of the Orchid Committee of the Royal Horticultural Society, will be pained to learn of the death of his wife and of the circumstances leading up to it. It appears that Mrs. Bond had been in a nervous and depressed condition for some few days, when her youngest son, a boy of about seven years, and who was playing in a meadow where a two-horse roller was at work, jumped on the roller for a ride, and, unfortunately, fell, and the roller passed over him. The ground was soft with the rains, and he escaped with a fractured skull, but is now thought likely to get over it. The shock, coming as it did at a time when she could least withstand it, caused the mother's death. In order to remove Mr. Bond for a time from the scene of his troubles, Mr. Ingram is sending him on a tour through France.

THE LATE MR. W. G. HEAD.

departure at this nursery. We need hardly mention the Vandae as most gardeners are aware that they succeed admirably here. The Cattleyas also, and the Orchids generally were looking well. There was not much bloom to be seen, but the following were noticed amongst others:—The new *Eulophiella Elisabethae*, *Ada aurantiaca*, *Dendrobium cucullatum giganteum*, *Vanda suavis*, *Laelia cinnabarina*, *Cattleya citrina*, *Cymbidium Devonianum*, *Cypripedium exul*, *Dendrobium Wardianum*, *Oncoglossum crispum*, *O. cirrosum*, &c. *Vanda* trees is just showing its flower spikes.

A house full of *Cliveas* in bloom make a good display, and include many fine varieties, notably one called *Queen Victoria*, which was noticed in our report last week of the Royal Botanic Society's show. An adjoining house is full of *Hippocrepis* in flower.

Palace was maintained, was often the theme of well-merited praise.

Mr. Head's experience as a gardener was very varied. At an early age he first entered the then very famed gardens at Arundel Castle, in his native county, he having been born at Worthing. Here he met Mr. A. F. Barron of Chiswick, and began a friendship which lasted to the end of his life. Leaving Arundel he went to Shrobbard Park, Ipswich, famous for its gardens at that period; and then, to Drumlanrig under Mr. McIntosh. We next find him in South Wales for a short time, cultivating Pine-apples; and then as foreman in the Royal Horticultural Society's Gardens at Chiswick, with his friend, Mr. Barron. From Chiswick he went to the Royal Gardens, Kew, where he stayed some time; and thence went to India, to take charge of the

SOCIETIES.

ROYAL HORTICULTURAL Scientific Committee.

MARCH 22.—*Present*: Rev. C. W. Dod (in the Chair); Mr. J. Douglas, Mr. Michels, Dr. Muller, Rev. W. Wilks, Dr. Bonavia, and Rev. G. Henslow (Hon. Sec.).

Balls with Arrested Rots.—With reference to the samples sent to the last meeting by Mr. Atkinson, Mr. Douglas was of opinion that the treatment had perhaps not been quite advisable, for he thought that they should have been put out-of-doors, and not in a shed, and covered with 6 inches of Coconut fibre. If, however, there was something deleterious in the samples sent for inspection, this could at once be ascertained by an analysis. Such, however, would be beyond the province of the Society.

Wireworm among Carnations.—Mr. Weguelin of Torquay asks for remedies against this trouble. The suggestions of Linseed cake, Carrot, scopolin, Potatoes, &c. for slugs, &c. were made, but it would appear that in the present case they are too numerous for such traps, unless the writer admits. Gas-line was recommended as the only very efficient remedy, but it might injure the Carnations. The land having been well-dressed with lime or soot shows that these ingredients are quite insufficient, though gas line would probably have been effective.

Carnation Leaves Damaged.—Mr. Egents of Honey Pots, Westfield, Woking, sent some leaves with peculiar red-streaks upon them. They were forwarded to Kew for further inspection.

Germination of Mushrooms.—Inquiries were made by Mr. Bicker of Chatham Park, as to the somewhat contradictory statements in books upon this subject, as in Mr. J. Wright's *Primer of Horticulture* it is stated that it has been observed, whereas in Dr. Scott's *Fungus-less Plants* (p. 268), it appears to have never been seen. Mr. W. G. Smith, having been appealed to by the secretary for his opinion, writes as follows:—"I have many times seen the spores of the *Mushroom* and its allies germinating. With me they have often quickly germinated on glass, and more often on moist blotting paper. The fungi must be allowed to shed their ripe spores on to the moist paper. After a day or two a damp microscope slide must be placed upon the part of the damp paper where the spores have fallen, and it will often

happen that some will be found to have germinated. I have seen the germinating examples whilst drawing the spores with a camera lucida. . . . Messrs. Wood of Wood Green managed to get spores of the Morel (from material sent by me) to germinate and Fern spore. I once exhibited before the Royal Horticultural Society a specimen of Coprinus, a rudimentary one raised by me from spores. This species can be easily raised (and it is not very far removed from the Mushroom) from spore to perfect fungus. The time it takes is three months. I believe some of the French manufacturers of Mushroom spores have had specimens directly from the spores. The spores of some of the allies of the Mushroom germinate readily in expressed juice of horse-dung. I have many times seen them, and am not the only person who has seen them on glass.

Trouton's antipeccator, Hartig.—Dr. Flouright sent a specimen of this fungus "to illustrate the mode in which it develops its hyaline spore upon the roots of an affected Scotch Fir. The hyemium is resinate. The fungus finds an entrance into the roots of living Fir-trees by the extremities of the mycelian hyphae insinuating themselves between the bark scales. It rapidly extends between the living bark and wood, and soon reaches the wood itself, so that it attacks the roots. The mycelium can travel in the ground from tree to tree.

Barley-smut.—Dr. Flouright also sent the following communication upon the injurious effect of this fungus upon the colour of the crop. "It is only a few years ago—a very few when one looks back upon it—that our attention was drawn by Mr. J. J. Jensen of Copenhagen to the fact that there are two distinct kinds of smut upon Barley. At that time there was a general opinion as to the distinction of two smuts as being due to two distinct species of Ustilago, but since they are not only easily distinguishable by the unaided eye, but also differ in the size and form of their spores, and as the latter have been found to germinate in a totally distinct manner, there is now no doubt about it. Our American correspondent the other day repeated the measures suggested by Mr. Jensen, and confirmed their efficacy; but here the matter stopped, for the simple reason that the damage done by smut was trivial, and from a monetary point of view the dressing of seed Barley was a needless expense. A few days ago a circumstance came under my notice which materially alters the whole aspect of the matter. A gentleman is rather an extensive grower of Barley in West Norfolk, drew my attention to the fact that two years ago his Barley was of an excellent colour while it was in the stack; but when it was threshed it was so discoloured that he had to reject a very large portion thereof. He attributed the damage in colour to the number of smutted spikes, which remained intact when the crop was harvested, but which, by being broken up in the process of threshing, discoloured the whole sample, just in the same way as blight would do so. Fortunately, he had kept some of the discoloured Barley. On inspection it was as if it had been damaged by exposure to the weather. When a handful of it, however, is shaken in a test-tube with clean water, the water becomes discoloured, and a drop placed under the microscope is seen to be full of Ustilago spores. So convinced is this gentleman of the cause of the discoloration, that in the next season he dressed his seed Barley with the ordinary sulphate of copper dressing, which is used for seed Wheat for the prevention of blight. The result was eminently satisfactory; for that year his crop was free from the disease, and the grain, of good colour, realised a proportionably good price. The ordinary Ustilago earvis, as it used to be called, has no distinct effect. A healthy crop, beyond destroying a certain percentage of plants, its spores being all blown away long before the harvest; but with the species in question, which, by the way, has received already a considerable number of names—Mr. Jensen originally called the variety *retro*—the ears retain their shape, the awns do not fall off, and the kernels are converted into solid compact masses of black spores; not so compact, however, as to withstand the concussion of the threshing-machine without being disintegrated into fine powder, which becomes scattered over the healthy kernels." With this communication were received:—(1) Specimen of the compact form of Barley-smut, gathered on July 15 last, at which time the common Barley-smut had all disappeared from the field. (2) Three samples of Barley, two of which are discoloured by the smut, as may be shown by shaking them in water and examining the washings. (3) A sample of healthy Barley from which no spores could be washed."

A note of thanks was unanimously given to Dr. Flouright for his interesting communications.

Portuguese Laurel with Defective Foliage ("Silverleaf Disease").—Rev. W. Wilks showed branches, one healthy for comparison, the other showing a silvery appearance. It is a well-known case, and apparently attributable to defective nutrition. The peculiarity resides in the fact that the upper epidermis becomes detached, and the presence of it gives the whilch appearance. The pulvinate tissue also separates readily from the mesophyll, and its cells are easily broken asunder. There is no trace of fungi or other organism. Mr. Henslow observed that a tree in his garden exhibited the same appearance and died. Its roots were found to have penetrated pure gravel.

PEOPLE'S PALACE HORTICULTURAL.

April 1, 2.—The spring show of this Society took place in the Winter Garden, and showed a fine collection of exhibitors, the exhibits forming a fringe to the collection of the same specimens plants which are the permanent occupants of this

building. The schedule is divided into three sections. The first, for those exhibitors residing in the more open and favoured spots, such as Forest Gate, Leyton, on the boundaries of Victoria Park, &c.; second, those members residing in the more densely populated parts, as Limehouse, Stepney, Poplar, Plaistow, &c.; and a third, for children residing anywhere in the district. Altogether, there were fifty-three classes, and very few in which no entries were made. Some excellent Hyacinths and Tulips were staged; and in the class for those at the first named, pot-grown, some remarkably fine spikes appeared. The improvement in the quality of the Hyacinths exhibited since this show was established is encouraging. Some pairwise collections of six pots were staged. Tulips, three bulbs in a pot, were also good, but less well done were the Polyanthus Narcissus. Collections of pot-growing leafy annuals were represented by bright, well-grown and bloomed Chimeras—white Primroses, Cyclamens, Anemones, Ficus elastica, &c. In the class for three flowering plants, Azaleas and Richardias were prominent. The three best foliaged plants, which, though they came from one of the more open neighbourhoods, had been grown in pots, consisted of a very fine specimen of *Aspidistra*, a *Ficus tremula*, finely developed, and a good plant of *Arumcaea elatior*. The best specimen foliaged plant was *Ficus elastica*, 4 feet or so in height, and well feathered with leaves down to the pot. The whole character of the show speaks well for the activity shown by this rapidly-growing society.

CARSHALTON, BEDDINGTON, AND WALLINGTON HORTICULTURAL.

MARCH 31.—The annual anniversary dinner of this flourishing Society was held on the above date in the Public Hall, Carshalton, H. COSMO BOSSOR, Esq., President, presided, assisted by J. HALSEY, Esq., M. H. SPUR, Esq., President of the Society, and other gentlemen of the neighbourhood. Letters expressing regret at being unable to be present had been received from Sir Trevor Lawrence, Bart., Rev. W. Wilks, M.A., P. Crowley, Esq., and supporters of the Society.

Mr. SPUR, in response to the Chairman's toast, "The Beddington, Carshalton, and Wallington Horticultural Society," said, in the course of his remarks, that the Society was started in 1880 in a little schoolroom at Beddington Corner. They had twenty exhibitors. Gradually they had improved in prosperity, and he must say that they had been helped by the Technical Education Committee of the County Council, which found them judges who were above suspicion. They had invited persons from outside districts, and had thrown open the amateur classes to all Surrey. They had also started a society for the encouragement of small parties of walking. They had shown that open also to the county of Surrey. Let them have good honest competition, and improve their horticulture and poultry-keeping. They should not look upon it simply as a question of putting money into their pockets, because they could do that without having any show at all. He believed that the improvement which had taken place in horticulture in this district had been largely due to that Society, and that he took a hurried tour through Kempe, and the only place in which they had allotments similar to the allotments in this country was near Breton. There the smaller tradesmen and the laborious cottages of ground and cultivated them, but he did not think their cultivation was to be compared to the cultivation of the allotments in Surrey—at all events, in that district. There was another thing they had done by that Society. They had, with the help of Mr. Halsey, had a show of Potatoes, which he believed had never been equalled. In that show they had Potatoes of the same class grown in different soils. The result was that in some of the soils some of the Potatoes did badly. Last year Potatoes in this district went rotten wholesale. So impressed was he with the result of the Conference the year before that he had a quantity of Potatoes heavily limed with manure, and when they were planted, and those Potatoes came up clean, a very small amount only of blight, and, of course, one year was not sufficient experiment, so he should try it again on a larger scale. He also found that if Potatoes were dug were sprinkled with lime, they kept free from disease in the clamps to a large extent. The Society had been able to put in many of the present time they had a sum of about £112 or £114 in hand, in case they had an unsatisfactory show lay.

Other speakers addressed the meeting at considerable length.

ROYAL CALEDONIAN.

April 7, 8, 9.—With winter lingering in the lap of spring light bright sunshine and genial air were almost despair of, the thoughts of the council of the Royal Caledonian Horticultural Society turned not lightly to the best of their annual series of Edinburgh shows. The past month is said to have been the most backward March experienced since the spring show was instituted, and as gardeners were reported to be finding considerable difficulty in bringing forward a marked fallow in the number of entries, the Council were fully prepared for this. These fears have not been realised, as a matter of fact the entries were within many of those of last year, which, with some entries, obtained the record show. This is exceedingly satisfactory, and equally so is the general nature of the exhibition.

The bulk was flowering plants, and if a stronger representation of foliage plants would have enhanced the show from one point of view, visitors to the Market will, in such a season, be disposed to do anything but quarrel with the wealth of flower. In this connection it may be mentioned that the Council have given effect to a suggestion which added very much to the interest of the show, the floor of the Market being broken up in insular groups, instead of having long lines on straight tables. As usual, the leading firms of nurserymen gave their valuable support. Messrs. R. B. LAIRD & SONS and THOMAS METHEVEN & SONS were, for instance, the largest of the groups. Of course, Messrs. LAIRD'S exhibit comprised some lovely Anemones, seedling Cycladas, and new varieties of Indian Azaleas, while Messrs. METHEVEN showed well-flowered Clematis, not usually seen at this time of year, Liliums and Azalea Mollis. The gardeners' groups were smaller, but very effective. Mr. M'INTYRE, of the Glen, was never better represented, his new dignity of member of the council having probably led him to improve even on his splendid register in former shows. There was probably nothing in the show so remarkable as Mr. M'INTYRE'S exhibition of greenhouse Rhododendrons, which were perfectly flowered. We understand that the conduct of the Society has decided to give a special award in this case, and to confer a similar distinction upon a display of magnificent Cyclamens staged by Mr. LUNT, Dumlinda. Azaleas and forced plants were the features of the show, Hyacinths occupying a subordinate position. In London, Messrs. BARR & SOS sent sixty varieties of the flowers, which they made up a beautiful table at the north side of the Market.

The following are some of the principal prizes:—
GARDENERS AND AMATEURS.

- PLANTS.**
Table of plants, circular, 12 feet in diameter, for effect.—1st, Mr. M'INTYRE, The Glen; 2d, G. WOOD, Oswald Road, Edinburgh.
Ten forced plants in bloom, not fewer than eight varieties, excluding Hyacinths and Tulips.—1st, M. M'INTYRE; 2nd, W. BENNETT, Humeley Lodge, Gogar.
Six forced plants in bloom, distinct varieties, excluding Hyacinths and Tulips.—1st, M. M'INTYRE.
Five Azaleas or Greenhouse Plants, in flower, distinct varieties, and not more than two Azaleas.—1, M. M'INTYRE; 2nd, J. COCKER, Christ's Hall.
Four Novae or Greenhouse Plants, in flower, distinct varieties, and not more than one Azalea.—1st, M. M'INTYRE.
Four Azalea indicæ, pots not exceeding 9 inches.—1st, M. M'INTYRE; 2nd, J. GILCHRIST.
Three foliage plants, distinct species, exclusive of Palms.—1st, J. MCCABINE, Liberton; 2nd, W. BENNETT.
Six foliage plants, pots not exceeding 9 inches, exclusive of Palms.—1st, D. MACVAY, Kinghorn Grange; 2nd, M. M'INTYRE.
Six table plants, distinct varieties, pots not exceeding six inches.—1st, D. MACVAY; 2nd, M. M'INTYRE.
Six Palms, in pots, not exceeding 9 inches—1st and 2nd, G. WOOD.
Six Roses, in pots, distinct varieties.—1st, D. MACVAY.
Twelve Cyclamens, not fewer than three varieties.—1st, T. LESTER; 2nd, J. GILCHRIST.
Six Cyclamens.—1st, T. LUNT, Dumlinda.
Four pots *Abayardis*.—1st, W. GALLOWAY; 2nd, M. M'INTYRE.
Six *Chimeras*.—1st, D. KING; 2nd, J. CUMMING.
Five Japanese Impels, in pots.—1st, A. LAIRD, Salisbury Green.
Four Orchids, distinct varieties.—1st, M. M'INTYRE; 2nd, F. NICOLL, Perth.
Three Exotic Ferns, distinct species, exclusive of all others, for which prizes are offered.—1st, J. NAPIER, Rockville; 2nd, J. BATHURST.
Three Adiantums, distinct varieties.—1st, J. NAPIER; 2nd, J. M'FARLANE.
Six Dwarf British Ferns, distinct varieties.—1st, J. STEWART; 2nd, J. BRISTON.
Three Lycopods, distinct species.—1st, T. GIBBS; 2nd, G. WOOD.
Six *Primula sinensis*, not fewer than three varieties.—1st, J. F. NAHRIE; 2nd, M. M'INTYRE.
Six *Anemones*, Alpine, distinct varieties.—1st, G. LEE; 2nd, R. STANARD.
Six Alpine Plants, distinct species, excluding bulbs.—1st, A. PATRICKSON; 2nd, T. M. WHITEHEAD, Schkirn.
Twelve Hyacinths, distinct varieties.—1st, G. M'DONALD, Duddley; 2nd, R. KEE, Sunlawes.
Six Hyacinths, distinct varieties (amateurs).—1st, D. WYLM; 2nd, A. BEYDON, Innerleithen.
Six Pots Tulips, distinct varieties, pots not exceeding nine inches.—1st, A. BEYDON; 2nd, G. WOOD, Oswald Road.
Six Pots spring Bulbs, distinct varieties, exclusive of all others for which prizes are offered.—1st, J. NAPIER, Rockville, Murrayfield; 2nd, A. M'INTYRE, Irvine.
CUT FLOWERS.
Collection of Cut Dwarf-wall Flowers (not *Polyanthus Narcissis*), not fewer than fifty different kinds.—Rev. G. P. HAYDON, Half-ford Viarage, Dunfermline.
Twenty-four Roses, not fewer than eight varieties.—1st, G. MANSON, Bathgate; 2nd, D. KING, Musselburgh.
Twelve Roses, not less than six varieties.—1st, W. ARMSTRONG, Musselburgh; 2nd, A. BEYDON, Innerleithen.
Six Twelve Roses, known as Bijou.—1st, A. COOK, Mid-ford; 2nd, G. M'DONALD, Duddley.

Twelve Roses, Mairchal Niel.—1st, G. M. DOUGALL; 2nd, G. MANSON.

Twelve Camellia blooms, not fewer than six distinct varieties.—T. BOWMAN, Lasswade.

FRUIT (OPEN TO ALL).

One Pineapple, not less than 4 lb. in weight.—M. M'INTYRE, The Glen.

Six pots Strawberries.—1st, M. M'INTYRE; 2nd, J. CUMMINGS, Liberton.

Two bunches Grapes, Black.—1st, W. SMITH, Ouseford Castle; 2nd, H. KIDD, Garbary Tower, Musselburgh.

Twenty-four Kitchen Apples, at least six varieties.—1st, G. MACKINLAY, Wrist Park; 2nd, J. DAVY, Garliestown.

Twenty-four Dessert Apples, at least four varieties.—1st, J. CAHIN; 2nd, G. MACKINLAY.

VEGETABLES (OPEN TO ALL).

Collection of Vegetables, twelve distinct kinds.—1st, W. HARPER, Path.

Two Cucumbers.—1st, J. GRAHAME, Wishaw.

Two bunches of Grapes, white.—W. SMITH, Ouseford Castle.

Basket of Mushrooms, not less than one quart.—1st, S. TANNER, Mountslade Drive; 2nd, J. GRAHAME.

Fifty Pots French Beans.—1st, J. WALKER, Dollar; 2nd, J. COSSAR, Dunbar.

Six Heads Sea Kale.—1st, W. COLLINS, Stoney Hill.

PLANTS (OPEN).

Twelve Hardy Rhododendrons, distinct varieties.—1st, R. B. LAIRD & SONS, Murrayfield.

Four Azalea Indica, distinct varieties.—1st, J. DOWIE.

Eighteen Forced Plants, not fewer than twelve varieties.—1st, J. DOWIE.

Twelve Forced Plants, not fewer than six varieties.—1st, J. DOWIE.

Six Palms, in pots or tubs, distinct species.—1st, LAIRD & SONS.

Twelve Conifers, in pots or tubs, distinct varieties.—1st, DICKSON & SONS; 2nd, LAIRD & SONS.

Twenty-four evergreen shrubs, distinct varieties.—LAIRD & SONS.

Twelve Japanese Maples in pots.—1st, LAIRD & SONS; 2nd, J. DOWIE.

Twelve plants for table decoration, distinct varieties, pots not to exceed 6 inches.—1st, LAIRD & SONS; 2nd, J. DOWIE.

Six Anemones, Alpine, distinct varieties.—1st, J. DOWIE.

Six Anemones, stage, distinct varieties.—1st, J. DOWIE.

Twenty-four Hyacinths, not fewer than 12 varieties.—KEITH & SONS, Roxburgh.

Six pots or pans Tulips, distinct varieties.—A. E. CAMPBELL, Gourock.

—Extract from "Edinburgh Evening News," April 7.

COLONIAL NOTES.

RHABDADENIA BIFLORA, Muell., Arg. (ECHITES BIFLORA, Jacq.).

The scentless tubular flowers of this are from 2 to 2½ inches wide when fully open, and in colour of a pure white, with the throat yellow. The whole plant is glabrous; its opposite leaves are of a milk-white beneath, dark green above, wedge shaped at the base, and abruptly terminated by a small point or mucro at the top of the leaf. The pretty climber grows in the Mangrove swamps, and lights up the sombre green colouring of the Mangroves with its white flowers when in bloom. The flowers are followed by cylindrical-shaped pods, inside of which lie the elongated seeds, tasselled at one end by a tuft of fine white hairs. Among the West Indies, it belongs also to Grenada.

ARECA CATECHU.

The Betel Nut Palm is represented by many permanent specimens growing in the rich Palm collection of the Botanic Garden, Grenada. The object of the present note is to chiefly state how highly fragrant are the small white flowers which are produced in large quantities together. Not unfrequently, visitors to the Botanic Garden have wondered from whence the fragrance has come, the chances being, that just beside them is a flowering Betel Palm.

ECHITES SYMPHYTCARPA, Mey.

Whether this be really the above species or not, it is a plant fully worthy of notice in a horticultural journal. Most of its characteristics agree with those given in Grisebach's Flora of the British West Indies, but not so clearly as to make it quite certain that it is the plant described. Beyond this, we have nothing further for the moment to guide us. It is a climber, densely covered with hairs; and the attractive flowers 2½ inches wide are very showy, the centre being

vermillion-coloured surrounded with a broad band of yellow, externally it is of a downy white. The plant is continually in flower. As might be expected, a copious white juice flows from the plant when the fruit is cut or ruptured. The larger leaves are about 5½ inches long, by 2½ inches wide; the length of the seed pod is about 5 inches. There are plants in the Botanic Garden which were raised from seeds received from Trinidad, of which island it is a native, and where it fruits freely. It is doubtful whether this beautiful climber is known as a cultivated plant in Europe. Hitherto, no seeds have developed on our plants. The scent of the flowers is like that of the Pomme Molac, or Malacca Apple (Eugenia malaccensis).

SEEDLINGS "DAMPING OFF."

The "damping off" of seedling Cloves (Eugenia caryophylla) and Sweet Oranges (Citrus aurantium), oftentimes causes much loss and disappointment at the Botanic Garden, Grenada. In the case of Cloves, our supplies of self-sown seedlings come from a higher and cooler atmosphere than exists in the neighbourhood of the Botanic Garden; and the other hand, the air in our shaded open plant-sheds, where moisture is always more or less present, resembles to a great extent that of the lower mountains. Ferns, and other plants from the mountains which are subject to the same conditions, do well, yet the Clove does not. The plant has been tried in all sorts of positions, from dense shade to full exposure to the sun, yet in none has success resulted. I do not suppose that on an average we get 1 per cent. to grow. Again, with the Sweet Orange seedlings, unlike the Clove, these are raised from seeds sown in seed-boxes. Several dozen boxes, it may be, are sown, crowds of young plants come up, and yet perhaps fifty to eighty, or even more, in every hundred, die without any apparent cause. In some cases, side by side some boxes may be seen without one dead seedling, while others without exception have all withered away, though all may be from the same lot of seed, sown at the same time, and also in the same compost, so failure cannot be attributed to imperfectly formed seeds. Why, therefore, should one box of seedlings be sound, and the next, although well filled with healthy young seedlings, shrivel up in a day and die off? The loss we sustain in this respect is both discouraging and serious. Can anyone reading this article suggest a remedy?

PIPER (POTHOMORPHIC) PELITATUM, Linn.

A representative of that class of plants known among horticulturists as "soft-wooded," and one that is known in the colony of Grenada as Chapeau d'Eau. Its leaves, dotted with innumerable white points, are large and circular in outline, 12 or more inches long, and about the same in breadth; they are covered with veins, and in colour are dark green above and milk-white beneath. The long leaf-stems are winged at the base and upwards for about 3 inches. When bruised, the whole plant emits a strong odour. The petiole is attached 2 to 4 inches from the base of the large, round, leafy portion, thus forming what is known as a petiole leaf. The lower or older main stems are roughened by little warty excrescences, which are present on the bark; whilst near the top of the plant the young stems are quite smooth, and covered with a glaucous bloom. The numerous tiny white flowers are produced upon erect, slender, catkin-like fingers, the common stem or peduncle to which several are attached being axillary. For a stove foliage-plant, this would be worth growing. Here it is found in shady and damp places, attaining a height of only a few feet. The native inhabitants use the leaves in cases of headache as a sort of bandage tied round their heads. H. E. Broadway, Grenada.

A NEW YELLOW-SPOTTED RICHIARIA.

The photograph mentioned in your issue of Jan. 23, in Colonial Notes, of a plant grown at Rhine Villas, Sea Point, Cape Colony, is doubtless that of the plant which was exhibited at the last show held in the grounds of the Cape Agricultural Society. I happened to visit this show, and noticed this plant, but instead of this being a new variety, it appeared to me

to be a well-grown plant of the true *Richardia Elliotiana*. Probably Mr. Ross may have seen other spotted-leaved varieties, and thought they were *R. Elliotiana*; but he has the true *R. Elliotiana*, and apparently he does not know it. The plant grown and exhibited by Mr. Ross was in every way a credit to him. J. R. R.

MARKETS.

COVEY GARDEN, APRIL 8.

(We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Ed.)

CUT FLOWERS.—AVERAGE WHOLESALE PRICES.

Table with columns for flower types (Anemones, Arums, Azaleas, etc.), quantities, and prices per doz. Includes sub-sections for Orchids and Plants in Pots.

PLANTS IN POTS.—AVERAGE WHOLESALE PRICES.

Table with columns for plant types (Adiantum, Aspidistra, Begonia, etc.), quantities, and prices per doz. Includes sub-sections for Fruit and Vegetables.

FRUIT.—AVERAGE WHOLESALE PRICES.

Table with columns for fruit types (Apples, Figs, Grapes, etc.), quantities, and prices per doz. Includes sub-sections for Vegetables and Onions.

VEGETABLES.—AVERAGE WHOLESALE PRICES.

Table with columns for vegetable types (Artichokes, Asparagus, Beans, etc.), quantities, and prices per doz. Includes sub-sections for Potatoes and Onions.

POTATOES.

To be strictly, supplies fully equal to the demand. Dunbar Maincrop, 75s. to 85s.; 140s. to 150s.; 75s. to 85s.; 140s. to 150s. Maincrop, 100s. to 110s.; 140s. to 150s. Maincrop, 100s. to 110s.; 140s. to 150s. Maincrop, 100s. to 110s.; 140s. to 150s.

SEEDS.

LONDON: April 7.—Messrs. John Shaw & Sons, Seed Merchants, of Great Malze Pond, Borough, London, S.E., write that there is now an improved sowing demand for Grass, Clover, and other field seeds, under the influence of which stocks are being reduced to moderate limits. The orders which come to hand are executed at the low rates characteristic of the present season. Lucerne, Sainfoin, and Timothy realise former terms. Tares move off slowly, and are cheaper. For Mustard and Rape-seed the market is firm. There is no change this week in either Canary or Hemp seed. Bice Peas and Haricot Beans are in better request. Linseed is weaker. Scotch and White Runner Beans are obtainable at tempting rates.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and the difference, when expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

DAYS.	TEMPERATURE.				RAINFALL.	BRIGHT SUN.					
	ACCUMULATED.										
	Day-deg.	Day-deg.	Day-deg.	10ths inch.							
0	7	0	55	-	6	4	65	11	45	40	
1	7	-	6	54	-	14	20	56	57	67	40
2	5	-	3	55	+	34	62	2	59	64	39
3	3	-	16	32	+	44	104	1	57	71	29
4	3	-	14	32	+	36	94	1	54	79	51

11	9	over	38	0	+	106	711	1	70	118	41

The districts indicated by number in the first column are the following:—
 0, Scotland, N.; 1, Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S.; 6, Principal Grazing, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; 11, Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending April 3, is furnished from the Meteorological Office:—

"The weather during this period was very changeable, fine and bright intervals alternating with considerable falls of rain, sleet, or wet snow."

"The temperature just equalled the mean in the Channel Islands, and was only 1° below it in England, S.; in the other districts, however, the deficit was greater, that in England, N.W. and N.E. being 2°, that over Ireland 2° or 6°, while that over Scotland ranged from 6 to 7°. The highest of the maxima were recorded on March 28, when the thermometer rose to 58° in England, E., and 57° in several of the other English districts and in the Channel Islands, to 60° in Scotland, E., and 47° in Scotland, N. The lowest of the minima, which were registered on March 30, were very low for the time of year. They ranged from 19° in Scotland, E., and 18° in Scotland, N., to 23° in Scotland, W., 24° over Ireland, and to 26° in England, S. In the Channel Islands the thermometer did not fall below 30°."

"The rainfall was greatly in excess of the mean in England, S.W. and the Channel Islands, and rather considerably so in England, S., England, N.E., and Ireland, S. In Scotland, E., the fall was just equal to the normal, while in all the other districts it was deficient."

"The bright sunshine exceeded the mean value in Scotland and the northern parts of England and Ireland, but was somewhat deficient in most other parts of the kingdom. The percentage of the possible duration ranged from 45 in Scotland, N., and 41 in the Channel Islands, and the Channel Islands, to 21 in the Midland Counties and England, S., and 29 in England, E."

A SHOWER BOUQUET: J. M. This is an arrangement of flowers, foliage, and ribbon, secured in a bouquet-holder of satin, paper, &c. which, instead of being circular in form, streams over, as it were, on one side, like liquid poured from a pitcher. The material of the bouquet has to be "wired," and is lightly bound up, so that it is readily grasped. Tall stands of stout brass wire are sold at some florists, to enable such bouquets to be placed on a table.

DEVONIENSIS ROSE: U. M. The plant may be dead; most Roses having, under ordinary conditions, broken into growth.

FIGS: A Subscriber, Worsop. The Figs sent are not suffering from any organic disease, but the cause of their appearance was external, and, as it seems to us, was produced by some sudden chill or change of temperature. M. G. C. [The check alluded to is the cause of imperfect fertilisation, hence the rotting of the fruits from the apex downwards. As the season advances so will the malady disappear.]

FLOWERS FOR WEDDING IN SEPTEMBER: J. M. We may name the following: Tuberoses, retarded Lily of the Valley, and Lilium longiflorum; Roman Hyacinths, some species of Jasmine, as Sambac; Tea Roses, German Asters, Early Chrysanthemums, single and double-flowered Pelargoniums, double-flowered Petunias, &c.

FUNGUS IN MELON-BED: H. K. The material sent from your Melon-bed is a fungoid substance which grows over all kinds of dead vegetable matter, tan, loam, &c., and is called Fulguria varians. This is one of those curious organisms, the Myxozoyetes, which some people say is as such an animal as a fungus. You must get away as much as you can of the surface-soil in your beds, and replace it with fresh, and possibly you may get rid of the pest; but in this doubtful now that it is so firmly established, and the millions of spores are everywhere. M. C. U.

INSECTS: J. L. The flies sent belong to the genus Bibio, nearly related to "daddies," although so different in appearance. The grubs are very much alike, and have the same habits, hence there was apparently an error in the previous identification. They are said to be highly injurious, especially to roots of grass. It is very probable that in your case they were introduced with manure. R. McL.

NAMES OF PLANTS: Correspondents not named in this issue are requested to be so good as to consult the following number.—H. G. Dendrobium fimbriatum.—W. S. N. There is a created variety known as Adiantum cuneatum grandiceps. It is similar to yours so far as we can judge by the fronds sent.—J. M. B. Cattleya Percivaliana, but it usually bears more purple colour on the front of the lip.—T. B. K. A very good variety of Dendrobium noble. The large single flower is Bifrenaria Harrisonii, more commonly known in gardens as Maxillaria Harrisonii.—E. H. North Hales. Not Cyrtopodium hirsutissimum, but C. Boxallii.—J. R. Your Dendrobium Wardianum is of a very distinct character if it remains constant. The plants are good flowers of their kind. J. F. A. Vanda Amesiana; B. Miltonia flavescens; C. Cyrtopodium punctatum, a species very remarkable for the showiness of its floral bracts. H. C. B. A very fine Sophronitis grandiflora. The fresh-imported Dendrobium noble is large, and very brightly coloured.—Corypodium? Pinnis pinaster. G. C. Many thanks for the specimens. We believe they are all correctly named, except that T. gigantea, is the true original T. plicata. In gardens the name gigantea may be conveniently retained.—A. B. Yours is the semi-double purple form of Vinca minor.—T. P., North Devon. Lælia Bothernia, more commonly known in gardens as Cattleya lobata.—Savertin. Cereus flagelliformis, figured in the Botanical Magazine, vol. i., t. 17, as Cactus flagelliformis.—J. W. McL. The Cerium form of Cymbidium aloifolium, which was known as C. bicolor. Your Beech shoot is affected, which, for want of a better name, we call the silver-leaf disease. It is probably caused by a fungus, and is very destructive; cut all the affected shoots away and burn them.—W. H. The white Orchid is

Dendrobium barbatulum; the other, Cirrihopetalum fimbriatum. The figs contained no perfect seeds.—Reader. 1, Odontoglossum odoratum; 2, Oncidium luridum; 3, Cattleya Trianei delicata; 4, Cattleya Trianei.—T. Mah. A, Selaginella denudata; B, Selaginella viticulosa.—Wants to Know. 1, Adiantum cuneatum; 2, Adiantum capillus-veneris; 3, Adiantum gracillimum; 4, Tritoleia uniflora.

PLANT LEAF: Cebania. The leaves are affected with the fungus, Pestalozzia phaeospora, see Gardener's Chronicle, p. 129, vol. xxiii., 1884; cut off and burn every affected leaf. There is no cure. Occasionally spray healthy plants with the Bordeaux Mixture.

PEACH LEAVES, DISCOLOURED AND CURLED: W. H. D. The so-called "silver-leaf" disease, the leaves have a silvery appearance, because the entire cuticle of the leaf is separated from the subjacent tissue, and is now being devoured by the aphides, which are so plentiful about them. There is no trace of fungus disease.

PRIMULA CORTUSOIDES: D. W. C. M. C. We were not aware that this species of Primula caused any irritation of the skin, although P. obconica has such effect on some persons.

SALTING ASPARAGUS BEDS: U. M. The quantity used should not exceed at one dressing 3 oz. to the square yard.

VINE FOLIAGE AND SHOOTS: W. H. The specimens sent indicate the presence of the Downy Mildew, Plasmopora viticola. See Gardener's Chronicle, p. 75, July 21, 1894. The first thing to do is to cut off and burn every affected leaf without delay, as it is a fungus that soon spreads by means of its spores. If this be not done, the mycelium spreads from the leaves to the shoots, where it may possibly remain until the following year, only to break out anew. Spray with the following solution: 1 lb. of pure sulphate of copper, dissolved in 40 gallons of water, and apply in the evening. As a preventive, this mixture may be used a few times before the Vines flower.

VINE BORDER: Amateur. The Vine being a sun-loving plant, it is in this country inadvisable to sow or plant anything on the outside border of a vinery, unless it be just at the margin, where you might sow Mignonette, or other annual of dwarf growth, or plant Ten-week Stocks and German Asters.

VINES: Vitis. Kindly send us better specimens. We suspect it is the malady known as "Browning," due to a slime fungus. See answer to W. H.

WEED AND MOSSY LAWN: U. M. Spud out the larger weeds, filling up the holes caused by the extraction of the roots with loam; then with a long-toothed iron rake free the turf of the moss, and apply the dressing you mention after sowing a little law-grass mixture on the bare spots. Wood-ashes may form one-fourth; lime, one-eighth; and the remainder loam. The lawn should be well rolled when not in a sticky condition. Slight dressing of wood-ashes may be afforded twice or thrice during the summer. Do not apply the salt. The lawn may require draining.

COMMUNICATIONS RECEIVED.—M. D.—J. W. E.—C.—Mrs. D.—H. T. (with many thanks).—J. A. L.—F. W. B.—Costa Rica.—W. R.—H. E.—C. H. T.—E. D. T.—M. F.—J. M. T. (with many thanks).—O. T.—G. S.—H. W.—A. E.—J. CONTINUED LARGE INCREASE in the CIRCULATION OF THE "GARDENERS' CHRONICLE."

IMPORTANT TO ADVERTISERS.—The Publisher has the satisfaction of announcing that the circulation of the "Gardener's Chronicle" has, since the reduction in the price of the paper, increased to the extent of more than 90 per cent., and that it continues to increase weekly.

Advertisers are reminded that the "Chronicle" circulates among COUNTRY GENTLEMEN, and ALL CLASSES of GARDENERS and GARDEN-LOVERS at home, that it has a specially large FOREIGN and COLONIAL CIRCULATION, and that it is preferred for reference in all the principal Libraries.

THE

Gardeners' Chronicle.

SATURDAY, APRIL 17, 1897.

PLANT DISEASES.

UNTIL quite recently the task of convincing gardeners that plants could suffer from specific diseases was in most instances difficult; and if, in addition, it was suggested that such diseases could be cured, or, at least, checked in their course, the information was usually received with a smile or an outburst, depending on the temperament of the recipient. This condition of things is the result of the education received by most gardeners having been purely practical or imitative, consisting mainly in following those methods which past experience has proved to be most successful; at the same time adding to the general fund of knowledge, the outcome of personal experience and tact. The lack of a broader grasp of the fundamental laws which govern plant-life than can be acquired by the imitative method alone, is often very evident when a gardener is called upon to cultivate plants under different conditions than those to which he has been accustomed, and it is to be regretted that after the expenditure of years of diligent labour in acquiring a knowledge of the practical part of the subject, the gardener should be handicapped through lack of information relating to subjects which are, in reality, of the utmost importance in connection with plant-culture.

It is still sometimes urged that what is usually termed theoretical knowledge, is of no value to the practical gardener; nevertheless, it must be conceded that it is always a source of satisfaction to have a clear idea as to the reason why one mode of procedure yields more satisfactory results than another; and it can scarcely be doubted but that the time devoted to attending a few lectures and demonstrations bearing on the broad principles of vegetable physiology, would throw a new light on many points previously ill understood, and consequently lead to a better method of meeting in a practical manner, special requirements. Such practical lessons are given by the Essex County Council at Chelmsford, and should surely be carried out at Chiswick. The same may be said of plant-diseases; the various fungus parasites, many of which are terrible pests, have their own peculiar mode of life, their weak points also, which if understood on broad lines, would save the gardener many a bitter disappointment; but being ignorant of these laws, when a disease appears, an attempt is made to cope with it in a manner which, in many instances, rather favours than checks its spread, and the end is disastrous. "Prevention is better than cure," and the gardener whose knowledge enables him to anticipate a danger, based on

past experience in combating the same, is most likely to evade a calamity.

A book recently published* deals with those plant diseases caused by fungi, bacteria, slime-fungi, and Algae, and may be described as the best and most comprehensive work on the subject in the English language. It is a somewhat massive volume of nearly 600 pages, and contains 330 figures, illustrating the appearance of plants suffering from various diseases, and also the fungi causing such diseases. "Though it will be possible to identify most of the more important parasites by the aid of this book, we do not intend it to be so used as to replace the systematic works; we propose rather to add to the descriptions given in *Rabenhorst*, *Saccardo*, and similar works. This book is intended above all to be, in the terms of its title-page, an introduction, hence it seeks in a general way to give a summary of our knowledge, and to indicate the way to more detailed records." The above quotation from the author's preface indicates clearly the line of treatment adopted; it is essentially a student's book, but presupposes a considerable amount of special knowledge relating to the subject. Nevertheless, some of the introductory chapters may be carefully studied with advantage by those desirous of becoming acquainted with the practical part of the subject only. On the other hand, to the teacher or student of plant pathology, in the proper sense of the term, the book is simply indispensable.

The translator states that he has modified to some extent the original, so as to adapt the work to the requirements of English readers, and it would not have been a subject for regret if the modification had been extended to the exclusion of the numerous lists of fungi parasitic on weeds, which have no economic importance. Such strings of scientific names do not inspire confidence in the beginner, and their absence would be no loss to the advanced student.

Agaricus destruens, Boud., is given as a British species; this is probably a slip. On the other hand, *Sclerotinia Galanthi*, Ludw., a disease too well known with us, is not included as British. We learn that in Prussia the loss from grain-rust during the harvest of 1891 on the crops of Wheat, Rye, and Oats, amounted to the sum of £20,628,117 sterling, being nearly a third of the total value of the crops. Forest and horticultural produce suffers in equal proportion, hence the necessity for systematic and universal measures for combating such diseases, which through ignorance, are at the present day too frequently aided in carrying on the work of destruction.

We are perfectly conscious that it is inconsistent with our own views, and perilously near being an insult both to author and translator, to suggest a rule-of-thumb method, even as means to an end; but we are compelled, however reluctantly, to admit, that in this country, the methods for combating plant diseases are very imperfectly known, and we feel convinced that if a copy of chapter vi.—Preventive Combative Methods—could be made readily accessible to every person occupied in the cultivation of plants, it would facilitate the entrance of the thin edge of the wedge, and lead to a desire to become acquainted with the entire contents of the volumes of which it formed a part.

* *Diseases of Plants*, &c., by Dr. Karl Fröhner von Tubortz. English edition by William G. Smith, Ph.D. (Longmans).

NEW OR NOTEWORTHY PLANTS.

PHAIUS × NORMAN (SANDERIANUS, Hort., × TUBERCULOSUS), new gard. hybr.

HOWEVER correctly it may be to place the *P. Sanderianus* imported some years ago by Messrs. Sander & Co. under either *P. grandifolius* or *P. Wallichii*, there is no doubt that as a garden plant it is far finer than any of the species before imported, and a marvellously strong grower. Its colours are bright, and vary very much in the different specimens, and the elongated deflected front of the lip is a distinct feature by which to identify the plant, as a variety at least. It was these distinct characters which induced Mr. Norman C. Cookson, of Oakwood, to cross a fine variety of it with *P. tuberosus*, in order to attempt to produce an improvement on the favorito *P. × Cooksoni*. Four of the hatch are now in flower, all of them rather lighter than *P. × Cooksoni*, which, however, the new variety resembles in a general way; the main differences being in the more prominent display of bright yellow lines radiating from the base of the lip, and the more elongated and lighter-coloured front to the same. The sepals and petals vary from cream-colour to pale pink, their surface being lined and tinged with yellowish-pink or copper colour. The base of the lip is reddish-purple, veined with bright yellow, and bearing three yellow keels at the centre; yellow on the under side. The front lobe is rose-coloured, blotched with purple, changing to nearly white at the tip! It is a very strong grower, and an acceptable showy garden plant, which will probably thrive in a warm greenhouse or conservatory, and, like *P. × Cooksoni*, be available for decoration in the dwelling-house. *James O'Brien*.

THE ATOLL OF FUNAFUTI.

AN expedition under the auspices of the Royal Society was made for the purpose of obtaining borings in the coral reefs of Funafuti. Mr. Hedley, of the Australian Museum, Sydney, accompanied the expedition, and succeeded in making rich collections in various departments. Mr. Hedley has favoured us with a copy of his general observations on the natural history of the Ellice group of islands, from which we extract the following:—

"The vegetable monarch of the Atoll world is the *Coccoloba palm* (Coccoloba nutans). Lowly tall individuals of which, rearing their plumes to a height of over 80 feet, give to the mariner his first landfall. Every available rod of dry land is planted with *Coccoloba*; one tiny slip, a mere shingle bank, so swept with spray that lichens are the only other vegetable life, yet grows dense, poor stunted and battered *Coccoloba*. It is to be emphasised that all *Coccoloba* are planted; the idea of a wild *Palm* being as strange in Funafuti as that of a wild Peach being in England. Gill, in describing the primeval forest of the uninhabited island of Nassau in 1862, alludes to but a single *Coccoloba* tree among the indigenous vegetation. I doubt whether, despite popular opinion to the contrary, a wild *Coccoloba* *Palm*, is to be found throughout the breadth of the Pacific. Certainly it is most rare, again contrary to popular theory, for a drifted *Coccoloba* thrown upon the beach by winds and waves to produce a tree!

"Palms devoted to the manufacture of toddy are readily distinguished by having steep-notches cut in their trunks.

"Gill, *Jullings from the Pacific*, 1857, p. 30.

"From eye witnesses I have heard of several wild *Coccoloba* palms on Facing Island, Queensland, and again of one at Euan Park, Queensland. But, if the popular idea were correct, the Queensland beach-woods have presented many hundred miles of *Coccoloba* groves to their earliest explorers, receiving, as I can testify they do, abundance of drifted nuts, and fulfilling every requirement of soil and climate. As Jukes says: 'The entire absence of these trees from every part of Australia is a most striking fact, since, as is, believe, the only country in the world so much of which lies within the tropics, in which they have never been found.' (Vol. 'Fly' 1, 1847, p. 132.) I have been told by Queensland aborigines that they always tore up and ate any sprouting nuts they might find; but even this scarcely accounts for the remarkable absence of the *Coccoloba* *Palm* from Queensland. Mr. Jukes' remarks on the germination of stranded *Coccoloba* nuts (*Colony*, XI, p. 492, will repay perusal; also Dana's, in *Coral and Coral Islands*, 1875, p. 181. Where the original home of this *Palm* was to have been discussed at length by Seemann, in the *Flora Frœnsis*, and by De Candolle, so intimately is this *Palm* now associated with native life that it is difficult to imagine an Atoll *Palm* not its indigenous. *Origin of Cultivated Plants*, 1884, p. 429.

Every month the Palms put forth a budding-spathe. In todays Palms this is not permitted to develop into flower and fruit but on its first appearance is lashed round with twine, "mailed" in searing language, from the base to the apex. The peduncle of the spathe is scraped and slightly split, to allow it to bend more freely. Then the spathe is bent downwards gradually by tying down the tip for two or three days, the cord being shortened at intervals, till the spathe has acquired the proper inclination. Three or four inches are cut off with a knife from the tip, to which a little spout or gutter of lead is attached. This spout directs the drip of the sap into an empty Cocoa-nut shell hung from the spathe. Twice a day a lad ascends the tree, unbinds the tip, shakes a little off it with his knife to make the sap run freer, re-binds it, and exchanges the full shell for an empty one. Several spathe in one Palm are in operation simultaneously.

"The cultivation of the Cocoa nut is confined to the simple operation of placing a sprouting Nut where it is to grow, or of clearing the shrubs and vines from around it, and of gathering the produce. The work of collecting and husking the Nuts depends solely upon the men. For climbing the Palms a stout rope loop, "kafunna," is twisted into a figure of eight; into this each foot is thrust as far as the instep. Placing his hands around the stem, the man leaps on to the trunk, resting his manacled feet on either side of it. Raising his hands to a higher grasp, he makes another leap, and ascends the tree by bounds of a couple of feet or so. Arrived at the sum-it, he places from his belt a short, notched stick and attached cord, "kouteki." Applying the stick against the palm-stem, like a ship's cross-tree against her mast, he winds the rope half round the trunk, and over the notch on the stick, back round the tree, and over the other notched end. Repeating this twice or thrice, the stick is securely hitched to the trunk, and the native standing upon the cross-tree may conveniently do his work. A hut is gathered by raising the apex with the fingers, and twisting it round till the twisted stick breaks, when the nut is allowed to drop to the ground.

"Temporary huts are thatched with Cocoa-nut, but Pandanus replaces it in permanent residences. A leaning Palm is used to collect rain-water, which, trickling down the stem, is turned by a wisp of leaves, and caught in a wooden trough.

ORCHID NOTES AND GLEANINGS.

LELIA - LATONA.

A SPIKE of this hybrid nearly a foot in length, and bearing three very beautiful flowers, has been received from T. W. Thornton, Esq., Brockhall, Wrecon, who raised the plant which produced it from seed obtained by crossing *Laelia cinnabarina* with *L. purpurata*, the seed having been sown in November, 1889. The same cross was first flowered by Messrs. Jas. Veitch & Sons, who exhibited it under the above name in 1892. Mr. Thornton's variety seems larger in the flower, but this may arise from superior strength in the plant. It also has the labellum almost entirely of a dark claret-purple, and without the lighter colour at the tip as in the original. The sepals and petals are of a clear reddish lilian-yellow, and the whole flower very attractive.

CYPRIPEDIUM NANSSEN (SELLIGERUM MAJUS - MORGANIE), new gard. hybrid.

In this fine hybrid the ancestry is *C. superbiens* and *C. Stonei* on the one side, and *C. barbatum* and *C. philippinense* on the other; and so four species of different geographical ranges have been concerned in its production. To those who know hybrid *Cypripediums*, it will be best described as bearing much resemblance to both the fine *C. Youngianum superbum* (*superbiens* - *philippinense*) and to *C. Denisonianum* (*selligerum* - *superbiens*), illustrated in *Lindley's*, vol. x., p. 13. The leaves are bright green with a darker green veining. Scape dull purple, two-flowered. The flowers have the upper sepal 2 inches long and nearly 2 inches wide, white, with a green tinge at the base, from which about twenty purple lines radiate. Lower sepals small, r., and with green lines. Petals 5 inches long, 1 1/2 inch broad, whitish, with numerous purple spots, the edges ciliate. Lip large, slightly grooved down the front, greenish, tinged with pale purple. Staminode large, ciliate, cream-coloured, veined with green. *J. O. F.*

"The thatch of Atapa's house (in Nuanetsi) is merely the leaf of the palm, which is very peculiar to rain-land, while the thatches are well covered with the leaf of *Pandanus odoratus*, the finest thatch in the world. We suggested to a chief that the chief's dwelling might have a better thatch. He replied, 'The king's house is thatched with Cocoa-nut leaves, not with *Pandanus*, because he is but mortal.' The same feeling existed in Mangina with reference to this celebrated thatch tree. - *Gill, Journals from the Cape*, 18 5, p. 22.

ORCHIDS AT OAKWOOD, WYLAM.

THE extensive and interesting collection of hybrid Orchids raised by Norman C. Cookson, Esq., and his gardener, Mr. Wm. Murray, is continually affording fresh examples of fine things from well-considered crosses. Here are no haphazard ventures, hence the uniform excellence of the novelties raised. As compared with results obtained by other raisers who cross anything and everything, at Oakwood but few seed-pods are saved, and with the raising of the seeds but little difficulty is experienced, while the progeny are invariably good and desirable additions to garden Orchids. The main difficulty experienced is in getting the seeds to germinate in exactly the place in which they were sown, and where the record-label, corresponding with the pedigree-book, appears. Sometimes it is found that the plants appearing under a certain record cannot possibly be true, and consequently they must have been dipped up from the water tank, or transported in some other way; and, being more prepared for germination than the fresh-sown seeds recorded, have usurped their place—for the time being at least. At other times a thing will appear which, bearing evidence of its parentage on its face, is found to be of a cross carefully sown in quite another place.

The Dendrobium-house has for a considerable period of time been a charaizing sight, filled from end to end with the beautiful flowers of plants which were one and all raised on the place. On one side are plants of the bright carmine-rose-tinted *Dendrobium* × *Harold* (*Linawianum* × *Findlayianum*); and on the other a fewer number of *D.* × *Sibyl* (*Linawianum* × *bigibulum*). There is a similarity in the flowers of these two beautiful crosses, although their habit of growth is different. Their bright and attractive flowers have few rivals among *Dendrobiums*, either species or hybrids.

Suspended overhead were several of each of two lovely crosses of *D. luteolum*, viz. *D. Astrea* (*luteolum* × *crasinode*), with fine pale sulphur-yellow flowers, with the tips of the segments rose-coloured; and *D. Bryan* (*luteolum* × *Wardianum*), with handsome flowers of the same creamy yellow tint as *D. luteolum*, but much larger. In these two crosses, as in so many garden hybrids, the bad habit and difficult growth of one of the parents (in these cases *D. luteolum*) is done away with, and better flowers, more profusely produced, on plants easy to manage, are secured, which in itself is a sufficient plea for the pursuit of hybridisation. Of the white or nearly white varieties, *D.* × *Murrayi* (*nobile* × *albo sanguineum*) and *D.* × *Kenneth* (*MacCarthiae* × *Bensonie*) (illustrated in the *Gardeners' Chronicle*, February 27, 1897, p. 135) are two of the best; though the several distinct forms of the *D.* × *Cassiope* class; and of the white-flowered second crosses of *D.* × *Ainsworthianum*, both of which are represented in quantity, are good and profuse-flowering. A large batch of the bright rose-pink-flowered *Dendrobium* × *Dules* (*areum* × *Linawianum*) exhibits the free-flowering character of this cross. It was noted among the seedlings in this case there is some variation in tint, and one has flowers which are striped in a singular manner. Others observed in more or less quantity were *D.* × *Owenianum* (*Linawianum* × *Wardianum giganteum*), *D.* × *Venus* (*Falconeri* - *nobile*), a great beauty, and continuous bloomer; *D.* × *Doris* (*Leechianum* × *moniforme*), one of the best of the Cassiope strain; *D.* × *Corningianum* (*nobile* × *litaiorum*); *D.* × *Wiganie* (*splendissimum* and *D.* × *Aspasia*, var., a very fine form; both of the last-named having been acquired from Messrs. Veitch & Sons, Ltd.

The central portion of the stage occupying the middle of the house was filled with a large number of fine plants of varieties of *Dendrobium nobile* raised by Mr. Cookson in order to test the effect of crossing a good typical *D. nobile* with the trilabellod *D. n. Cooksoni*. The result has been the production of a very fine and varied series of *D. nobile*, which as regards the greater number, are like the type in shape, but in some cases larger, and possessing colours

equaling those of *D. n. nobiliss*. One variety, *D. n. picturatum*, has very showy bizarre or variegated flowers; and another (not raised in the batch), named *D. n. Arnoldianum*, has a repetition of the colouring of the labellum on the two lower sepals, instead of on the petals as in *D. n. Cooksoni*. Many other *Dendrobium* crosses were in bloom in the house, the only species noted being *D. strobilaceum*, which is destined for crossing.

In another house the show principally consists of numerous plants of the best forms of *Phaius* × *Cooksoni* (*Wallichi* × *tuberculatus*), the finest specimen of which, a plant bearing eighteen flower-spikes, having been recently exhibited at the Royal Horticultural Society, when it received an award of a Silver-gilt Flora Medal. In Mr. Cookson's opinion, it is one of his best crosses, but its full value as a garden plant has yet to be appreciated, when the beauty of the flowers, the ease with which it can be grown, and its durability are known. Mr. Cookson has the Orchids when in bloom in his drawing-room for a period of six weeks. Sojourn, under what must be regarded as injurious conditions, does not appear to affect the health of the plants in the least. In the same house was a batch of another cross between the fine *Phaius Sanderianus*, Hort., and *P. tuberculatus*; in its general characteristics it resembles *P.* × *Cooksoni*, except that the lip is longer in front, and the interior bears a number of clear yellow lines. Here, too, is the old plant of *P. tuberculatus*, which has been in use every year, and is still in flower; and although the habit is not nearly so robust as its offspring, the plant continues healthy.

In one of the Cattleya-houses the centre stage has the remains of a good show of *Cattleya Trianae*, and the prime of the *C. Schrodera*. The side stages are occupied by a very great number of hybrids of *Laelia* and *Cattleya*, *Epidendrum*, and many strange crosses, on the appearance of whose flowers it is interesting to speculate, although when the flowers are produced some of them will probably differ totally from what they were expected to be.

In one house *Laelia* aneps, principally varieties of whites, had bloomed well, and a large panful of *Cologyne cristata alba* must have been very fine. Here a fine specimen of *Cologyne ocellata maxima* was in bloom; and the handsome *C. pandurata* and others were sending up flower-spikes. On the centre stage were plants of *Anthurium Laiigi*, with pure white spathe, and *A. Burfordense*, the brightest of the dark scarlet varieties. Among the *Cypripediums* two more plants of the home-raised *C. Lawrenceanum* *Hyeanum*, illustrated in the *Gardeners' Chronicle*, Jan. 16, 1897, p. 37, are in flower, and prove to be equal to the one figured. *C.* × *Bryant* (*philippinense* × *Argus*) is sending forth its graceful spikes of flowers, which later, in some respects, resemble *C.* × *Morganie*, excepting for the large white upper sepal, closely striped with emerald-green. Here, too, was blooming for the first time a grand cross between *C.* × *selligerum majus* and *C.* × *Morganie*, which is an improvement on *C.* × *Youngianum superbum*, hitherto thought to be the best of its class.

Other fine plants noted in flower or bud were *C. callosum Sanderi*, a plant of which was much admired at the Temple Show when exhibited for the first time by Messrs. F. Sander & Co., and has increased in favour ever since; the fine *C.* - *Juno* (*callosum* × *Fairianum*), an advance on the kindred *C.* - *vestilium*; *C.* - *Pitcherianum*; and a number of others. In studying the well being of his plants, nothing that is deemed advisable to be carried out is shunned, and no point likely to be of use is too trifling to be considered.

The occupants of the cool-houses were in grand health, and as affording evidence of this was the presence of a small stock of each of a number of very finely-blotched varieties of *Odontoglossum crispum*, which have been worked up in each case from a single plant. Thus, of the famous *O. crispum Cooksoni* and some other varieties as rare, there are now six or seven plants of each. The raising of hybrid *Odontoglossums* is being pursued, and in due time it is not too much to hope that the recently-exhibited *O.* - *Halli-crispum* will be followed by others, though the

work of crossing *Odontoglossums* is less easy or sure than in other genera.

In the cool-house there were in flower a number of plants of *O. crispum*, *O. Halli*, *O. Pescatorei*, *O. Wilckeanum*, and some showy *Masdevallia*.

PADDOCKHURST.

This is a place of which few of our readers are likely to have any present knowledge, but it is one about which they may hear much in the future. Paddockhurst is a Sussex estate, and its location is about four miles from Three Bridges Station on the London, Brighton, & South Coast Railway. Crawley and East Grinstead are but little further distant in other directions.

Sir Weetman Dickinson Pearson, who a short time since acquired the estate of about 3000 acres by purchase, had no sooner entered upon possession than he determined to build extensive ranges of glass-houses, and to enlarge the pleasure-grounds and flower-garden, with a view to obtaining in them what horticultural features and effects the conditions of their site would allow. Extensive work to this end has been carried out under the management of the eminent landscape gardener, Mr. H. E. Milner.

THE GLASS STRUCTURE, &c.,

or, at least, such part of them as is not being done by the estate mechanics, are the work of Messrs. Mackenzie & Moncur. These have evidently been taken to culture; the materials used in all of them are of the best, and the woodwork throughout is of Teak.

The value of this wood for all such purposes consists in its durability, which has no comparison whatever with any woods that have been commonly employed in the erection of green-houses. On the other hand, its appearance is decidedly different from Pitch Pine or Deal when these are painted, and we must add when painted as often as necessary. The Teak has a stained, reddish appearance that is not quite to the taste of some persons, who are accustomed to white-painted woodwork.

Every house upon the place will be new, and all of them are nearing completion, except in the matters of interior furnishing and the approaches. There are four ranges of spin roofed plant houses about 12 feet wide and 8 feet high. Each range is 114 feet long, and is divided into four divisions, so that these alone represent about 450 feet of glass, and it is all of the most convenient description for the growth of plants of moderate size, or for Cucumber, Tomato, and Melon growing. If each of these divisions is devoted to the culture of plants of one affinity only, a very important aid to good cultivation will be secured at the outset. It is intended, we believe, to utilise one range in its entirety for the growth of Orchids.

There is an excellent Orchard-house about 120 feet long, 24 feet wide, and perhaps 11 feet high. The roof has three ridges and furrows. A partition divides the house into two divisions, and one part may therefore be used for slight forcing. Various fruit-trees for plunging or planting in this structure arrived at the time of our visit.

Rather nearer to the house is another range of glass 300 feet in length, most of it being three-quarter span. Here there are six vineries, a stove, a green-house, and two plant-houses, one at either end. In the centre a kind of connecting link will be in the shape of a dome of moderate height, to be used as a Rose-house.

The conservatory has been built adjacent to the new wing of the dwelling-house, upon the eastern side, and is about 90 feet long, 35 feet wide, and of considerable height. The disadvantages of this structure, owing to its being insufficiently provided with light, we are afraid will be considerable. If we may judge it in the half-finished state it at present bears, it is unlikely that any but shade-loving plants will continue to thrive in it for any length of time, and thus it will entail a continuous drain upon houses

more favourable to plant-growth. However, a free use of marble and other reflective mediums is intended, and when finished the building may appear more light than when we viewed it.

The very considerable extent of glass above enumerated will be supplemented by about 450 feet of Teak-pits.

Before disposing of the glass structures, it may be added that Mr. F. Capp, the gardener, is actively engaged in obtaining collections of plants for furnishing them. Even now, when the work engaged in necessitates much inconvenience to plant-growing, there is a praiseworthy display of bloom from a good strain of *Cinerarias* and other species of spring-flowering plants.

A wing has been added to the rather plain-looking dwelling-house. A residence for the gardener will be commenced shortly, and a convenient and well-appointed cottage for the young gardeners is in course of construction; besides which there are several necessary offices, storerooms, and such places to be built. The imposing-looking stables are inconveniently near to the dwelling house. Excellent arrangements exist for illuminating the house and grounds with the electric light.

PLEASURE-GROUNDS, &c.

Turning our attention to the pleasure grounds, there will be about 45 acres to be kept, if we include the flower-garden and the kitchen-garden yet to be made. The house stands on a slope, being neither at the summit nor at the base, and faces due south. The entrance from the west has already been altered and improved, and a new entrance will be made upon the eastern side of the estate, and a drive from this point will lead up to the dwelling-house, passing through an avenue of Chestnut trees. The more attractive portions of the pleasure-grounds and flower-garden are destined to be upon the east side of the house, and to the south of it. Unfortunately, as we think, there will be little "kept" ground immediately in front of the residence—indeed, only a few yards.

One of the natural advantages of the place is a semi-wild spot under trees, a hundred yards distant, directly south of the dwelling, where there are several small watercourses surrounded by high banks, and percolating through very uneven ground. Many rustic bridges have been erected at suitable points here, and there is a pleasant waterfall, quite strong enough as we saw it, but the supply of water may become much lessened in summer. Primroses, bulbs, and other suitable plants, have been planted by Mr. Capp, and he will no doubt make the most of the natural advantages of this spot. *Skimmia japonica*, scarlet Oaks, Batcher's Broom, Berberis, and *Rhododendrons*, will furnish the banks on either side of the streams. Intervening between this attractive wilderness and the front of the house is some grazing-land, so that the cattle may stray close up to the windows, consequently the house is reached by paths to the right or left, which enclose the grazing-land within a more or less perfect circle. We have already said that the flower-garden is being formed on the slope to the east of the house, but before this is reached, there is a little border contiguous to the conservatory on a kind of terrace. It has been cut up with a pretty design, and many small beds, but the effect would have been better had there been more space available. As this was not possible, however, a more simple design would have been suitable.

We can say but little upon the flower garden, as it was far from completion; but its general character, and several details in its arrangement, are certainly praiseworthy and most artistic. There are a few incongruities we admit, as for instance the four Yew trees, clipped into some resemblance to a peacock, one placed at each corner of a piece of beautiful greensward adjoining an Elizabethan garden, where infirmality exists to the extent that there are beds of choice varieties of dessert fruits that visitors to the flower garden may be able to gather some refreshing fruits. It is satisfactory to know that these tortoise trees had to be imported from Holland. In close proximity, a maze is to be con-

structed, consisting of Yews 4 or 5 feet high; and there will be two fountains, one upon this, and a second upon the other side of the house. The sides of one of the broad paths or drives are lined on either side with iron arches about 8 feet high, running in the same direction as the drive. *Malus floribunda* and *M. atrosanguinea* have been planted at each arch, and when well covered, these arches or chains will provide an unusual feature. We are glad to say that a good number of Roses have been planted, and it is evidently intended to create a remarkable display with Turner's *Crusian Rambler*.

A new kitchen garden of about 3 acres is to be formed. Altogether, the place is a very interesting one, and we shall have pleasure in taking an opportunity to visit the gardens at a subsequent time, when we may be in a position to place before our readers some notes upon the effect of the work we now allude to. Sir W. Pearson, who is an eminent engineer, may be congratulated upon the horticultural enterprise he has shown, and we hope he will obtain the amount of pleasure from his garden that his efforts deserve.

METHODS OF PROPAGATION.

(Continued from p. 215.)

ORNAMENTAL AND TIMBER TREES FROM SEED.—The Hornbeam, called in some counties the Buck Beech, rarely attains to any great size. There is a fine pollarded plantation at Mersham-le-Hatch, in East Kent. These pollards are cut about every seven or ten years, when they furnish a large quantity of good cord-wood and brush-faggots, the latter being used for brick-burning. It is also a most useful hedge plant, and may be used alternately with *Quick* (*White-thorn*). It can be raised from its seed, which are like small Chestnuts. These separate freely from their husks in the autumn, and may then be collected and sown at once, or in the following February or March.

The Spanish Chestnut, though not an indigenous tree, ripens its fruits in hot dry summers. The seed from trees at home is preferred by foresters to imported Spanish nuts, for two reasons; they are smaller, and consequently more numerically go to the bushel; and secondly, they will produce hardier seedlings. The nuts should be sown thinly on a dry floor, and frequently moved as well, and covered up during frosty weather. In addition to other feathered and furred enemies that feed on other tree-seeds, we have in this case to guard against the vole, erroneously called the water-rat, as well as from rats proper, who will work along the rows, and devour the just sprouting nuts, if not checked by trapping. A good plan is to pour a little common paraffin-oil into the bag containing the Chestnuts, and to give it a shake, so that every nut gets a little on it. If this be done the night before sowing, every nut will be flavoured with the strong-smelling oil, which will render them distasteful to both bird and quadruped.

In Kent and Sussex, large quantities of Chestnut-plants are raised annually to replenish woods and coppices, as Chestnut poles are in great demand as Hop poles, and to split to make rails for fences and other purposes. Chestnut-plants should never be grown in low damp ground, as the late frosts will kill back the young growth in the spring, when—even if cut to one leaf—a tedious and expensive process—the plants seldom make clean straight plants. The best soil for them is a stiff sandy loam, enriched with yard-manure, so as to insure a stout and rapid growth. The importance of the Chestnut for woods and plantations may be inferred, when it is known that such, compared with mixed underwood, realises double the price per acre.

The common Hazel is also used, but only in districts where the soil is thin. Hazel nuts are sown in drills, and in using them one has to guard against the elegant and active squirrel.

The Horse Chestnut (*Esculus*) is generally raised from the nuts, but is almost exclusively used as an

ornamental tree. A few seedlings should be raised for stocks to bud the scarlet-flowered and other ornamental varieties on, according to directions previously given in these columns.

The same may be said of the Walnut, which has valuable timber, is useful as a fruit-tree, and is also ornamental. While I am mentioning this I must not forget its first cousin, the Hickory, which in situations where it will thrive, makes an exceedingly handsome tree. There are some grand examples at Lees Court, near Faversham, the seat of Lord Soudes.

A tree not well known, but worthy a place in the arboretum, is the Planera, which is also raised in its seeds, or nuts. Both the Planes now so much in demand for street decoration in our cities and towns, and used with such happy effect in beautifying our noble Thames Embankment, are sometimes raised from foreign seed, but in English nurseries are propagated by layers from stools: though it is not difficult to raise the American variety from cuttings of the young wood, taken with a beel, and kept close in a cold pit.

Lastly, the Cherry, both *Cerasus sylvestris* and *C. vulgaris*, are raised from their stones, sown in drills, and transplanted when two or three years old to the nursery quarters, in which they are to be worked, i.e., budded or grafted. The different Plums used also in the trade for stocks, and considered in former papers, are raised from their stones, sown in drills; but patience will be found indispensable with all stone fruits, as it is not till the hard stone has partially decayed that the kernel can germinate.

The Wych or Scotch Elm is generally increased by seed, and is the variety generally used to graft on the English and other kinds; but it is not a very quick stock.

(To be continued.)

VIOLETS.

THE Violets, so common and so welcome at this season, are all descendants of the common *Viola odorata*. It is not suggested that any of the varieties are the result of hybridisation. The flowers are irregular in form, provided with a spur, and specially adapted for fertilisation by insects. The anthers form, as in other species, a sort of tube around the style. The style itself ends in a hook. When an insect visits the flower in search of the honey in the spur, it fits against the hook of the style, and presses it against the anthers, which thus set free their contents, and besprinkle the body of the insect with pollen. On alighting on another flower the pollen comes into contact with the hooked stigma, upon which the pollen is wiped off, and its fertilisation ensured.

But although cross-fertilisation is thus provided for, close or self-fertilisation often occurs. There are in Violets numerous inconspicuous flowers with green petals, which are produced after the coloured flowers, offer no attractions to insects, do not open, and are hence called "cleistogamous." The pollen of such flowers fertilises the ovules of the same flower. If, on the one hand, cross-fertilisation be a means of securing variation, close fertilisation, on the other, would appear to be a device for ensuring stability of characters and absence of variation. The raiser on the look out for novelties would, of course, eschew the seed produced by the cleistogamous flowers, though it is produced so freely, and prefer that ripened in the insect-fertilised flower. Vochting, as cited in *Willis' Manual and Dictionary of Flowering Plants and Ferns*, says that these cleistogamous flowers are specially formed in the shade. We do not know with what degree of frequency they are formed in the newer varieties. We may expect from this history that the variations which occur in these flowers will be variations in size and habit chiefly, and not of so remarkable a character as in the case where hybridisation intervenes. The illustration from specimens provided by Mr. Harry Turner, of Slough, and Messrs. H. Cannell & Sons, Swanley, show the typical *V. odorata* and some of the newer varieties (fig. 81).

Fig. 80 represents a form of *V. odorata*, known as *sulfurea*, and which was exhibited by Messrs. R.

FIG. 80. *VIOLA ODORATA* VAR. *SULFUREA*.

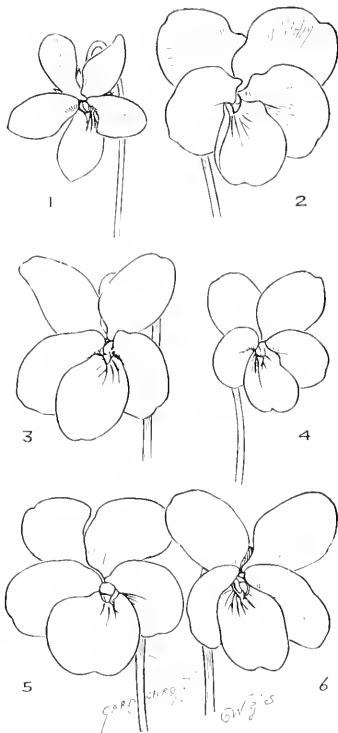

FIG. 81. VARIETIES OF VIOLET.

| 2. <i>V. Princess of Wales</i> . | 5. <i>V. Princess Beatrice</i> . |
| 3. <i>V. Primavera</i> . | 6. <i>V. Italia</i> . |

Veitch & Son, Exeter, at one of the recent shows of the Royal Horticultural Society, is reported to be a native of the South of France, and bears dull sulphur-coloured flowers. The figure, which represents a plant about the size of our wild *V. odorata*, may be compared with the relatively gigantic proportions of some of the newer ferns such as the *Czar*, *California* and others.

The second illustration (fig. 81) shows five of the newer varieties with a flower of the original species for the sake of comparison (1). For a few notes on the special characteristics of these varieties we are indebted to Mr. Turner:—

"*Princess of Wales* (2).—This is one of the largest single Violets in cultivation, the flowers being large and highly scented. The colour is a brighter blue than the *Czar* or other old varieties, the flower-stems are very strong, 6 to 8 inches in length, and the foliage is most robust, it is also a hardy variety, and flowers from September until April. See also fig. 82.

"*Primavera* (3).—This is an Italian introduction, and is rather darker in colour than "*Italia*," but very sweet and dwarfier in growth.

"*Aniral Avellan* (4).—This is a very distinct variety, the colour being rich purple. The plant is dwarf in growth, and it is very free-flowering.

"*Princess Beatrice* (5).—Another single variety, which is darker in colour than the *Princess of Wales*. It is not so robust in habit, but is very free-flowering. Mr. Smith, in making the drawing, made the interesting observation that this is the only variety destitute of a hairy fringe within.

"*Italia* (6).—A new variety, introduced from Italy last season. It is a free-growing and free-flowering variety. The flowers are a lovely shade of dark blue, and they rise well above the foliage."

California (see fig. 83).—As to this fine variety, Mr. House, of Westbury-on-Trym, furnishes the following interesting particulars. The new Giant Violet *California* is quite hardy, and a most rampant grower, with very large leaves, which are always to be had. It is easily propagated, and is a most prolific bloomer, with flower-stems frequently 10 inches to 1 foot in length. The flowers often measure from 1½ to 2 inches in diameter, are very fragrant, of an intense violet colour, which does not fade. *California* is already becoming a universal favourite, and the flowers will command high prices for some time to come. From a tradesman's point of view this Violet stands at the top. Although a profitable plant for open-air culture, it is unquestionably better for protection. The plan I adopt is as follows. Plant out the divisions or rooted cuttings, as the case may be, in April, in good deep soil, with a little rotted cow-manure mixed in. Give the plants plenty of room, and a position in partial shade for the summer months. Pinch off the runners and afford an occasional watering in dry weather; they will then grow very rapidly, and make strong clumps for lifting in September. Plant near the glass in light airy frames, and, if protection is necessary, use mats. This variety especially objects to heat.

The Violets like a lime-stone soil, and a seaside situation, which secures pure air; hence their culture in the immediate vicinity of London is becoming increasingly difficult, if not impossible. Articles on the culture of Violets will be found in our volume for the first half of the year 1889, pp. 137, 173, 201, 307, 373, 437, 532, 628.

GARDENING IN RUSSIA.

THE district of Wilna is celebrated for its market-gardens, which supply the greater portion of the fresh vegetables consumed in Warsaw and St. Petersburg in the spring, and with Melons during the summer months. The cultivation of vegetables is carried on, not by gardeners, but by raisers and improvers of vegetables—the so-called *Ogorodniki*. For raising the plants, 32,000 hot-bed frames or lights are employed in the spring months, and the chief articles raised at that season consist of "Stelen," i.e., Lettuce, Carrots, Parsley, Dill, Lettuce, and Radish. When the spring crops are gathered, the hot beds are utilised for the raising of Cauliflowers, Melons, and Cucumbers. Of the last named, almost

the only variety grown is the Russian (Trauben-Churke) Grape-Cucumber, which, although its fruits are very small, are produced in great abundance; and being aromatic, and of excellent flavour, they are eaten in preference to any other. The variety has the good property of scarcely ever failing to crop well, and it is hardly possible to form an idea of the abundance of the crop. A single Ogorodniki in one summer, daily harvests 4000 fruits.

Besides the vegetables raised and cultivated in hot-bed frames, large quantities are grown in the fields. These fields are divided into beds 1.75 metres (about 5 feet 9 inches) wide, the length being indefinite; and the beds are separated by alleys 0.7 metres (27.4 inches) broad, which are thrown out by the plough, and the earth thus loosened is cast over the beds, so that a bed has a height of 40 to 50 cm. Cart-roads do not exist. In the middle of each bed a row of Brunswick Cabbage is planted, on each side of which a row of plants of the Russian Grape-Cucumber or Gherkin is planted, which is a sort of the *Bino* of which does not spread widely. Next to these, on each side, come Red Beets; and lastly, as an edging all round a bed, one row of Potato-Onions is planted.

This method of planting is universally followed in the Wilna district. The leaves of the Potato-Onion are constantly cut, just as we do with our Chives, and these leaves form a part of the daily food of the Russian peasantry, who live for weeks on nothing better than black (brown) bread and some finely-shred Onion-leaves. In Nischni-Novogorod I obtained fresh caviare served with finely shred Onion-leaves, which, to us Western Europeans, seemed a horrible mixture. The Ogorodniki are of the opinion that by cutting the leaves of the Onion they increase the size of the bulb. However that may be, the Onions taste very nice eaten in the following manner:—First a slice of dry roll, and on the top of this a slice of Onion, above that one of Tomato strewed with caviare. *Probatum est.*

The first plants to become fit for consumption are the Potato-Onions, whose leaves, as I have remarked, are eaten by the folk with much gusto, and not despised even by the well-to-do. The Russian farmer is easily satisfied—a chunk of dry black-bread, and slices cut from a bundle, 1½ inch in diameter, of Onion-leaves, eaten as one consumes a sausage, serves for his mid-day meal. Onion-leaves are eaten in soups and with cold dishes.

In order to prevent the Potato-Onion from running to seed, they are, in the winter, exposed to a course of fumigation with wood-smoke for twenty-four hours. The cultivator continues to cut the leaves of the Potato-Onion up to the time when they begin to wither naturally. When the Onion-crop ceases to be productive, the Gherkin fruits begin to mature. The Russian Trauben-Gurke differs from most of the other European Gherkins or Cucumbers in its earliness, productivity, hardness, and being but little influenced by the weather. The fruit averages 1½ to 1¾ inch in diameter, and 3 to 4 inches in length, and may be consumed in the raw state, or as a pickle in brine.

Wilna possesses a very extensive nursery, in which fruit trees are chiefly raised. The proprietor, M. Wohler, also cultivates pot-plants in large numbers. Here it struck me as something peculiar, that despite the excessively severe character of the winters in this part of Russia, only single lights were employed on houses and pits; still more striking was the statement that these single glass-roots suffice to protect the plants in the severest frosts—32° Réaumur at St. Petersburg, and—35° Réaumur at Moscow.

The most important nursery is found in St. Petersburg, viz., that of Mr. Eiler, who has ranges of glass-houses, more than 2500 metres in length—say 1½ miles English—and the greater number of these houses are devoted to the cultivation of Roses. Formerly he used to cut Roses the entire year, but now, owing to the heavy importation of cut-blossoms of Roses from the Riviera and southern France, there is a cessation in the cutting in the autumn; a start being again made at Christmas, when flowers are sent to his numerous flower-shops and stalls in the

town. He cuts in the winter months about 2000 blossoms daily.

His method of cultivating the Camellia is interesting, and different to what is practised elsewhere. A lean-to glasshouse of great height and breadth is furnished with a stepped staging, on which are placed boxes running the entire length of the house, half a yard

amount of disturbance of the roots arising from this ensures a good set of flower-buds. The plants require nothing more than to be kept somewhat dry at the roots after they are established in the pots, and they flower freely in the winter months, being then disposed of at from five to six roubles a-piece; the value, therefore, of the plants having increased in one and a quarter year's twelve fold. Loss of plants or failure to set flower buds are rarely, if ever, experienced.

The number of the Lily of the Valley which are forced in Mr. Eiler's nursery is very considerable. The forcing of these roots is carried out in a house that is constructed inside of another house, and 1,000,000 (one million) crowns are forced yearly. The forcing of Hyacinths, Tulips, and Crocus is also carried on to a large extent; for besides supplying his own requirements, he furnishes the Imperial gardens with considerable quantities of flowers. A most desirable novelty noted in Eiler's nursery was a white, double-flowered *Petunia*, of fine form and agreeable aroma, named *Elise Eiler*. The variety is propagated by the thousand every year, the flowers forming excellent material for cutting. Of biological interest was the fact that during the months of June and July, when the nights are as light as day (St. Petersburg is situated under the 60th degree of N. latitude, therefore near the polar circle), *Cyclamens* scarcely grow at all, and only begin to grow with any vigour when the nights grow darker.

The cultivation of Carnations—18,000 plants—and Sweet Peas is largely carried on. The latter are sown in pots in the autumn, and later on they are planted in front of a trellis, furnishing flowers for cutting throughout the winter. *Udo Janner.*

(To be continued.)

HARDY CAMELLIAS.

MANY years have elapsed since I last visited Glen Eyre, the residence of Major Eyre Crabbe, and where the late Mrs. Crabbe converted a sort of heathy morass into a lovely garden. Glen Eyre is not far from the famous Red Lodge Nursery, and a peaty soil runs all through the district, so that *Rhododendrons* and American plants generally, as well as *Conifers*, flourish amazingly. The groups of *Rhododendrons* in Glen Eyre gardens have broken out into mounds, for they have grown wondrously, and are in the proper seasons literally huge masses of bloom. But the great feature of the place, without doubt, is found in the exceeding number of very fine *Camellias* growing in all directions, and in their season blooming profusely. The growth with most is almost luxuriant, and whether standing out on grass as single specimens, or growing singly as such on hardy plant borders, or jutting out from faces of ordinary shrubs, or found in masses, or planted against walls where they can now hardly be said to be trained, the plants are generally in first-rate form; and in growth, in richness of leafage, or in floriferousness, quite equal to anything seen in houses, even where they are planted out. It was very evident at Glen Eyre that *Camellias* enjoy rather rude treatment very well, for the hard cutting-back of any that seemed to become rather bare of leafage quickly led to the production of new and luxuriant growths. When to this new inspiration was added a little top-dressing of old manure and fresh soil, the plants soon became as robust as ever. There were a few varieties that seemed less robust than others, but that may have been due to some other cause, perhaps lack of essential food. All the same, it is evident that the natural soil is that which *Camellias* like, and generally, if deeply worked, it needs little artificial help. It looks, judging by what is seen in all directions, as if any varieties that are fairly good growers would do well out-of-doors at Glen Eyre. Doubtless, also, they would do equally well if planted south of London in similar peaty soil, and enjoyed similar surroundings. Many of these huge shrubs have been planted fully thirty years, perhaps longer.

The gardener, Mr. Stewart, who has been in the

FIG. 82.—VIOLET PRINCESS OF WALES. (SEE P. 24.)

FIG. 83.—VIOLET CALIFORNIA. (SEE P. 24.)

wide and 4 inches deep, and behind each box there is a narrow passage. The boxes are filled with a light kind of turfy-soil, and young *Camellia* plants brought in Germany for 90 pennings each are planted out in them in the autumn. The plants are syringed, not watered. When next year's growth is matured, i.e., when the latest leaf is become hard, the plants are taken out of the boxes and potted; and the small

family's service close upon forty-four years, commenced, in conjunction with Mrs. Crabbe, to lay out and plant the place forty years ago; and no doubt some of the Camellias were planted soon after. In any case, the trees and shrubs have grown together, and form a shelter from wild wind-storms. It must not, however, be concluded that, judged by what is seen under glass, the Camellia is at all a tender shrub. At Glen Eyre it is as hardy as any other in the gardens, and seems never to suffer from cold. No doubt intense sun-heat is the more objectionable, and hence here it is found that, in some parts, especially for those on walls, partial shade is furnished. There are, however, several very fine specimens standing singly on a south aspect, both on grass and gravel, exposed to the hottest of sunshine, and doing splendidly. Hence, it may be inferred that the Camellia is a very accommodating hardy shrub. As to producing bloom, position seems to make no difference. Whether in shade or in sunshine, nearly the whole of the plants are now blooming profusely. Generally, they carry buds in wondrous profusion, so much so, indeed, that did time and labour permit, it would pay well to largely disbud. As to the condition in which plants should be put out, Mr. Stewart has, because of his wide experience, no bias. He has planted (probably comparatively stunted ones, and strong, free-growing young ones. The latter have, of course, the sooner taken to the change, because better rooted. With the stunted plants the first year's growth is weak, but very soon the roots feel their liberty, and once they get well hold of the ground, soon produce strong wood-growth. When that is so, it is good practice to shorten back somewhat the more stunted branches, and in a couple of years a handsome well-wooded bush is produced. Plants in pots, hitherto grown under glass, should be allowed to make their spring shoots first, the planting out being done towards the end of April. Afterwards it is the habit of the Camellia generally to push the spring-shoots later, and thus they escape harm from late spring frosts. Amongst varieties, not a few of which have through so many years lost their names, are Old Double Red, Double White, McKay's Lowi, Duchess of Northumberland, Chandleri, Imbricata, Violaesuperba, Amemonifera, Old Double Striped, and some Italian varieties. Conifers are very fine in this place, and seem to be singularly at home on a steep sloping bank. *Paulownia imperialis* is here a very fine tree, the bole of the stem 4 feet from the ground being 3 feet in diameter. Skimmias are largely used for winter and spring decoration, whether plunged into vases or planted out into beds. The plants berry most profusely, and the birds do not touch the scarlet fruits. Presently the plants will go to the small nursery garden for the summer, and next winter will again do duty as now. So treated the *Skimmia japonica* becomes a beautiful decorative hardy shrub. *A. D.*

CHICORY IN WINTER.

THE following remarks do not altogether refer to the value of Chicory for salad purposes, but to its value as a vegetable when specially grown for the latter purpose. There are not many varieties of Chicory, and I consider the best to be Witloef, a Continental variety, that has been grown for some years in this country. This Witloef is largely grown upon the Continent, and esteemed as a winter vegetable, or for salad purposes; and I have noted latterly that a considerable quantity is imported into this country during January and February, and that it finds a ready sale.

I first grew the Witloef and stored the roots in a shed early in October—but there is no need to do so, as our roots stood the severe winter of 1895 uninjured; indeed, I find the roots winter best in the open if the soil is well drained. The common variety—Barbe de Capucin—is so poor compared to the Witloef, that it scarcely merits mention. The other kind most known is doubtless a selection from the common one, but with larger roots, and inferior to the Belgian type. These are very useful for

salads, as the leaf being cut up into small pieces, its size or shape matters little. Chicory with large tops blanches more readily, and does not run to seed so quickly. When used as a vegetable, it is advisable to get a good top-growth somewhat like Seakale, and if the Witloef is grown for the purpose, and forced slowly, it produces such growth. The Witloef is less bitter also than the older variety, and many who have tasted it find it more agreeable, while others value it for its distinct flavour.

Many err in sowing the seed too early in dry warm soils, to which it is apt to run to seed. Last year, owing to heat and drought, we did not sow till June, and even then germination was slow; but with the genial autumn rains the plants soon made head-way. In a light soil, June sowings gave a late winter supply, but on clay soils it would be better to sow in May. The plant requires plenty of room; it is a strong grower, and requires 2 feet space between the rows in good soil, or 6 inches less in heavy soil, thinning the plants in the rows to half that distance. Of course, this kind of culture is intended to furnish a vegetable crop, but even for salad purposes it is well to give the best cultivation, and thus obtain more material to cut from. During summer merely keep the ground clear between the rows, and if especially large-sized roots are wanted, afford a little liquid manure, which will produce a finer growth. I find, however, that roots large enough can be got without such food, and coarse roots are liable to run to seed. If I require to prepare the ground for another crop, the roots are lifted and placed in trenches rather close together, and winter them thus, removing the roots as needed to the Mushroom-house to force. The best way to do this is to place the roots in pots or boxes, and then invert empty boxes or pots over them. If required as a vegetable, cut the tops when 6 inches long, and cook like Seakale. It may also be easily forced in the open by covering with pots, &c., and placing litter over the covers, but damp soon spoils the heads if hard forced. *G. Wyllie.*

NURSERY NOTES.

CARNATIONS IN CAMBRIDGESHIRE.

NEAR to the March Junction of the Great Eastern Railway two young men—Messrs. Crane & Clarke—have established themselves as growers on a large scale of Tree Carnations, cultivating some 20,000 plants, a considerable proportion of which are vigorous, cleanly-grown plants of two years old, intended for the production of out-bloom for sale purposes. The proprietors gather Carnation flowers for about a period of ten months in the year. The leading varieties are William Robinson, a brilliant scarlet, which they recently exhibited in very fine character at one of the meetings of the Royal Horticultural Society; a vigorous grower, free of bloom, probably the finest of its colour in cultivation. Madame Thérèse Franco, which is better known in the London district under the name of Mrs. Leopold de Rothschild; Duke of York, bright maroon-crimson; Miss Mary Godfrey, and Primrose Day, a large pale yellow. The coming white variety is a new and scarce Deutsche Brant, a magnificent white, with large, full flowers, highly fragrant, good habit, and very free-blooming. A few others are grown, but the foregoing in by far the largest quantities. A new pink variety, a great improvement upon Miss Juliette, is spoken very highly of by Messrs. Crane & Clarke, but the stock of it at present is very limited.

White and pink Carnations find the greatest favour in the market, then scarlet, and next crimson; yellow being apparently least esteemed. A Tree Carnation is regarded as being at its best when two years old, and is then most productive of blooms.

An enormous number of fine young plants raised from cuttings struck in January is to be seen. They are now in 48-pots, and when they have reached the height of 9 inches or so, the leading shoot is pinched out; this causes the main stem to put forth young side-shoots freely, and in this way bushy, free-branching specimens are obtained. Clay's manure is applied as a fertiliser, but only when the plants are flowering, to assist the production of bloom.

Bouvardias, tuberous-rooted Begonias, and double-flowered Petunias in particular, are grown in large

quantities, and considerable numbers when in a young state are distributed by post. But Carnations are the leading feature, and it must be acknowledged that they are cultivated with great skill and success. An enormous number of young plants of Carnations are distributed from this nursery at this season of the year. *R. D.*

KEW NOTES.

CALIFORNIAN OR MOUNTAIN LAUREL (*ILLIPELLE-LARIA CALIFORNICA, Nutt.*).—An example of this interesting Lauracea is now flowering, though somewhat sparsely, on a wall in the open at Kew. In its native habitat it forms an elegant evergreen tree of from 40 to 120 feet in height, and from 2 to 4 feet in diameter, and has a smooth bark. The timber is of a light brown colour, hard and close-grained, and susceptible of taking a high polish, and in Oregon is used for a variety of purposes, the most important of which is ship-building; and, in fact, it is considered to be the most valuable wood of the Pacific forests for interior and cabinet work. The whole tree is highly aromatic, and the leaves, when bruised, give off a powerful eucalyptaceous odour. It has been stated by travellers that during a hurricane the odour is so strong beneath the shade of a forest of these trees as to provoke sneezing. Hunters are said to make a decoction of the leaves, which is used without any apparent injurious effect, to promote warmth. *J. M. H.*

PINUS THUNBERGI VAR. AUREA.

One of the brightest of winter trees is the golden variety of the Scotch Pine. During the spring and summer it is green, like the ordinary *P. sylvestris*, assuming its gayer dress during the autumn, and losing it again the following March. Until recently no other Pine was in cultivation that equalled it in colour, but now there is at Kew a similar variety of the Japanese *P. Thunbergi* (often called *P. Massoniana* in gardens), which promises, when thoroughly established, to be of at least equal value. Its golden colour during winter is quite as pronounced as that of the Scotch Pine just mentioned, and it retains it longer, being still, in April, of quite a bright yellow. Another variety—*P. Thunbergi variegata*—imported from Japan at the same time, may be briefly mentioned as also new to cultivation, although it is not, from the garden standpoint, so promising a tree as the other. In this variety the leaves are marked with one or two transverse bands of yellow near the middle, the remainder of the leaf being green as in the ordinary form.

CAMELLIAS OUT-OF-DOORS.

THE value of the Camellia out-of-doors in this country has scarcely yet been realised, except in the far south-west; but even as far north as Kew it is every year proving more beautiful and attractive as a hardy shrub. Of course, in bleak, wind-swept places it is not likely to thrive, but that much has to be said of many evergreens. In the Rhododendron Dell at Kew, in a spot shaded till noon, it has proved a perfect success, and as hardy as any Rhododendron. A group of plants was put out about eight years ago, and, except from the trees and shrubs around, had no protection. In spite of the severe winters during that period, they have increased in vigour yearly, and would be worth growing as evergreens for the deep shining green of the leaves alone. For the last few years they have flowered freely, and one variety especially—Donckelaari—has been most attractive. It is of free growth, and the semi-double flowers are of a rich scarlet crimson, the inner petals slightly mottled with pink. Hardy shrubs with flowers of this colour are very rare at any season.

PRENUIS NANA (THE DWARF ALMOND).

One of the prettiest of dwarf shrubs in flower is this bushy Almond, a native of Southern Russia. The abundant sunshine of last summer evidently suited it, for its flowers, both in the bud and fully open states, thickly wreath last year's wood. When fully expanded, they are three-quarters of an inch across, the five oblong petals being of a pale rose contrasting prettily with the deeper shade of the unopened buds. The flowers are borne in pairs a

each node, and from between them the young leaves, are pushing. These, when mature, are of a glossy green, lanceolate, toothed, and 2 to 3 inches long. This shrub is frequently worked on the Plum or some other stock, and is short-lived in consequence, which is, perhaps, the reason it is not so often seen as one would expect from its great charm and beauty. Budding is a quite unnecessary mode of propagation, for it roots freely when layered. A bed of young plants thus raised two or three years ago is in flower at Kew. It is likely to prove useful also for forcing, some plants of the same batch having flowered well a few weeks ago in the conservatory. W. J. B.

freely, each being $3\frac{1}{2}$ inches long, by $1\frac{1}{2}$ inch wide, and composed of fan-shaped scales with two seeds beneath each.

Though stiff in habit of growth, yet the branches being irregular of length, causes the tree to be informal of outline. It does not grow rapidly, and is therefore suitable for rather confined spaces. Some of the largest and best furnished specimens in this country are growing in peaty earth.

DAPHNE BAGAYANA.

Among early-flowering shrubs, this charming little *Daphne* is well worthy of mention. It is too rare, and requires, perhaps, conditions of too special a

In the open ground, we find it thrives well in a peaty soil, its roots covered with pieces of fairly thick porous stone. It can most conveniently be propagated by layering. *A. D. Webster.* [Figured in *Gard. Chron.*, 1892, p. 191. Ed.]

FLORISTS' FLOWERS.

THE HYACINTH.

It is probably owing to the fact that competitions with Hyacinths and other spring flowers do not occur in the present day, that so few novelties have put in appearance of late years. Thirty years ago, when

FIG. 54.—*PICEA POLITA*: BRANCH WITH CONES. (REAL SIZE.)

TREES AND SHRUBS.

PICEA POLITA.

Judging from the rarity with which one meets with the above-named tree in this country, it must be regarded as a rare species. This is unfortunate, for it is certainly one of the most distinct and beautiful of the Spruce Firs, and when once seen is not apt to be forgotten or confused with any other. The leaves are long, curved, and four-sided, broad at the base, comparatively persistent, and of a glossy green colour. They are produced all around the branches, but thickest and largest on the upper sides. The prominent brown buds are readily detected, they being often three-quarters of an inch long. Cones are produced

nature to ever become a very familiar plant in this country, but it is certainly one that ought to be represented as often as possible wherever suitable conditions can be provided. It is a low-growing, semi-prostrate evergreen, usually under 1 foot high, with dark green, narrow obovate leaves, 1 to 2 inches long. The flowers are crowded in a terminal cluster, and are of a pretty creamy-white, each flower half an inch across, and three quarters of an inch long. It is not only to the modest beauty of its flowers, but to their sweet perfume also, that this little *Daphne* owes its charm. It is a native of the mountains of Syria, and was discovered sixty years ago, but the date of introduction is given as 1872. It is essentially a rockery-plant, and succeeds best in a sunny spot, but with its roots kept uniformly cool and moist.

the names of Cutbush and Paul were closely associated with the culture of the Hyacinth for exhibition purposes, new varieties appeared annually, and a very brisk competition existed among raisers in getting their novelties grown and exhibited in this country. Now, new additions are rare; and probably one main reason for this is that so many fine varieties of all shades of colour peculiar to the Hyacinth are now in cultivation, that it is difficult to improve upon them; and good old varieties, many of which have been grown for a considerable number of years, still hold their own.

The double varieties, so much esteemed by our forefathers, are no longer favourably regarded. They lack the closeness, finish, breadth, and symmetry of spike which characterises the singles; hence the

reason the latter are more esteemed. Of the deeper shades of red, King of Scarlets, a comparatively new variety, is very brilliant in its rich crimson colour, and it produces a fine and compact spike; Etua, as its name implies, has a striking intensity of colour—its handsome bells gather into a symmetrical spike; Vesuvius, of a deep glowing crimson shade; and such standard varieties as Solferato, of a bright shade of rosy-red; Lord Macaulay, king of the reds; K-hi noor, which, though classed with the single varieties, is really semi-double; Lord Macaulay and Von Schiller make up the finest among the deep-tinted Hyacinths. Of more delicate shades of rose and pink are King of Roses, pale pinkish-rose, which forms a very handsome spike; L'Ornement Rose, clear bright rose, a very pleasing new variety; Moreno, bright salmon-pink, an improvement upon Norma; Pink Perfection, clear pink; and Belladonna, clear soft rose—a very good selection. Blue is always a favourite colour in the Hyacinth, whether the tint be dark or light; of almost black and dark-claret shades are King of the Blacks, very dark shining maroon; the Sultan, in the same way, but with more of white colour mingling with the black; and The Shah, dark violet. Of deeper tints of blue are Souvenir de J. H. Veer, dark violet-blue; King of the Blues, one of the handsomest and most reliable Hyacinths in cultivation; Duke of Clarence, rich bright blue; Ana Eolena, purple; and Masterpiece, dark violet. Among the lighter shades of blue there are some charming varieties, such as Beauty, soft azure-blue; Celestina, clear transparent blue; Forget-me-Not, a very pretty new light blue; Lothair, delicate azure-blue; and Queen of the Blues, soft and very lovely. Charles Dickens, an old variety, holds its own; it is sometimes light in tint, often much darker, but always good. The large-belled, pure white varieties are represented by Snow King, which has large bells of great substance; La Grandesse, L'Innocence, Madame Van der Hoop, and Snowball, all fine standard varieties. Of the smaller-belled pure white varieties there are Mountain of Snow, a reduced variety of great excellence, the handsome bells forming a compact spike; Mont Blanc, Lady Derby, and Alba maxima, a quartette representing the very best of blush and waxy-white tinted varieties, all of which it is customary to class under the general head of white; there are Charles Dickens, La Belle, La Frauchise, Grandeur à Merveille, probably the best blush-white single Hyacinths in cultivation; and Princess Marie, which forms a large and compact truss.

Very few additions are made to the yellow Hyacinths, and there is ample need for improvement; there are but few clear yellows, and they are pale, and the bells smaller generally than those of any other section. King of the Yellows is one of the best; it is the deepest in colour, and forms a very handsome truss. Primrose Perfection, Queen of the Yellows, Van Vondel, and Yellow Hammer, are all new varieties; the last the deepest in colour, Van Vondel being of a soft chrome-yellow. Bird of Paradise, and Ida are the best of the older varieties. The Yellows require high culture to bring them to perfection, and when well grown, and the spikes finely developed, they impart a pleasing variety to a collection.

RAISING SEEDLING PRIMROSES, POLYANTHUSES, &c.

The continued wet weather greatly interfered with the planting out of seedling Primroses, and Polyanthus obtained from seeds sown in August last. Seeds sown so soon as ripe germinate quickly, though to a considerable extent successively, as is the case with most of the families of Primula, a characteristic which is not without its advantages, as it enables the earliest plants, which are the most vigorous, and almost invariably the least valuable in point of quality, to be pricked off into boxes, and so make room for the other and later plants. Seeds sown in a light sandy soil in pans, spreading them thinly, and merely covering them with sand, quickly germinate, especially if pieces of glass be placed over the pan. We sometimes hear of complaints that the seeds do not germinate; but raisers are apt to be too im-

patient, and do not afford them sufficient time. Probably not a few pots and pans of seedlings have been thrown away in the belief that the seeds were bad; whereas, all that was required were time and the exercise of patience. Seedlings so raised, and then pricked-off into cold frames, are ready to go out in the open in March or April, when the soil is dry enough. Not a few of the strongest of these will flower in May or later, and all make fine plants for another season. The coloured Primroses and Polyanthus are at their best as strong two-year-old plants.

PENTSTEMONS, ANTIRRHINUMS, AQUILEGIAS.

The various types of Pansies, Aubrietias, Canterbury Bells, Foxgloves, &c., raised from seeds sown at the end of the summer, are ready to go out also, but the lightest soil cannot be trodden while blustering rain showers follow each other in such quick succession as they did in March. The sooner it can be done the better, for a long spell of dry weather may, and probably will, follow the wet winter—and it is therefore necessary that newly-planted things should begin to lay hold upon the soil. After much wet, it is necessary as soon as drying weather comes, to fork over the surface and well pulverise it, so that the newly-planted things should have a firm hold and get well into growth as speedily as possible; it will be helped if a little sand and husk-leaf-mould can be put about the roots of each. Happily at this season of the year the surface-soil soon dries, and becomes workable, though in the case of ground which contains clay, the heavy rains so beat it down that quite a hard crust was formed, and there is urgent need for breaking it into fragments as soon as the weather permits.

The wet weather appears to have done more injury to *Myosotis dissitiflora* than to any other spring flower. It never does so well as when it occupies a warm sheltered spot, where wintry storms scarcely reach it. I have never seen this beautiful *Forget-me-Not* finer than at Hayling Island, when the common Primroses are in full bloom. R. D.

THE WEEK'S WORK.

FRUITS UNDER GLASS.

By F. HARRIS, GARDENER, EASTNOR CASTLE, Leicestershire.

Pot Vines that are now ripening their fruit should be given plenty of ventilation, and although not allowing them to become at all dry, they will not require so much moisture either at the root or in the atmosphere. Where the fruit is required to hang for a few weeks, the Vines should be encouraged to continue making a little lateral growth, which will keep the roots in active condition, and thus assist to keep the berries plump and in good form. If very bright sunshine should occur, a little shade in the middle of the day will be beneficial to the black varieties; but in the case of white or yellow ones, turn the leaves back a little to admit direct sunlight. This, however, should not be done too soon or too rapidly, or the berries may become scalded, especially those of Foster's Seedling. If the house be damped down at mid-day it is sufficient for Grapes that are ripening, unless the weather is very hot and dry.

Early Vinery.—If the stoning period be past, and the berries have commenced their second swelling, a soaking of liquid manure of moderate strength may be afforded, at a temperature of 85°. If manure water is not available, sprinkle a good artificial manure over the border before watering. If it be necessary to hurry the Vines, take advantage of the present time, but damp down frequently and close early, allowing the temperature to run up to 95° with sun heat. The night temperature may be kept at 65°. Berries of red spider, as this is the time generally when it first appears. On its first appearance, sponge the little spot over with soapy water. Another excellent preventive, which I always follow, is to have a can of pure soft water placed in the house at closing-time, then at dusk, with a fine rose-nozzle on the syringe, I carefully spray the foliage between the bunches, wherever it can safely be done, especially near the hot water pipes. By this means the foliage is kept damp all night. If pure soft water only is used, there need be no fear of the bloom being damaged in the least, even should a little water reach the bunches, which we avoid as much as possible.

Succession Vineries.—The temperature of houses containing Vines in flower should be 60° to 65° for most varieties, with 65° to 70° in the case of Muscats; but should the weather be very cold, we often find it impossible to keep to these temperatures, and I have on several occasions seen my Muscat-house at 55° in the morning. If there is a good warmth in the pipes, and the house has a warm genial feeling on entering it, I do not think so much harm is likely to ensue as if the houses are excessively fired. We invariably get a good set here, with careful attention to fertilisation, and although we favour the temperatures mentioned above, high temperatures are not absolutely necessary, for if carried to excess they are often the cause of red-spider. Keep the shoots in succession and late houses just clear of the glass, and give due attention to stopping and rubbing off all weak and superfluous growths while in a small state, and gradually reduce them to the requisite quantity as it becomes apparent what are required to fill the trellis without overcrowding, always, of course, leaving the shoots which are carrying the best bunches of fruit.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorking.

Dendrobiums.—Many of the following species and hybrids will now be passing out of bloom, D. Wardianum, D. crassinode, D. noble, D. heterocarpum, D. Findlayianum, D. superbum, D. capillipes, D. prinnianum, D. Linawianum, D. cucullatum, D. cretaceum, D. crepidatum, D. Ainsworthii, D. Cassiope, X, D. Wigane, D. Douinii, D. Dulce, (Burfordense), D. condoharis, D. splendissimum, D. Venus, &c., and others. If any of these plants have become pot-bound, have them repotted at once, and place them in the East Indian-house or plant-stove to make their growth. All the varieties named above will grow well in Teak-wood baskets or shallow pans, which may be suspended close to the roof-glass, where they will obtain plenty of sunlight. Such plants as D. noble, D. splendissimum, D. Ainsworthii, D. Dulce, and D. Wigane, which produce strong erect growths, thrive thoroughly well in pots, provided they obtain sufficient light. For young seedlings and varieties of pendulous habit, small shallow pans, with perforations around their sides are preferable. Allow the plants to become quite dry previous to repotting, so that the old material may be easily removed. In the case of well-established plants root disturbance should be avoided as much as possible. My practice is to carefully break the old pot, and take away as much of it as is practicable, and if the drainage be filled with healthy roots, this is not disturbed, but the whole is placed in a pot a size larger. The space between the roots and the pot is filled with clean crocks up to within half an inch of the rim. The fresh potting material should consist of equal parts of fibrous peat and sphagnum-moss, with clean crocks added, and the compost should be pressed moderately firm around the plants. The necessary staking should be done immediately after potting, as it is difficult to do this without injury when the young roots are pushing freely through the soil. Healthy plants having sufficient room for further development should be relieved of the old compost from between the roots, even down to the crocks, and if necessary additional drainage may be given to lessen on the amount of compost about the plants. It is a great error to suppose it injurious to them. For such slender-growing varieties as D. Huttoni, D. O'Brienianum, D. purpureum, D. triadenum, D. Pierardi, D. sanguineum, D. lituiflorum and its rare variety candium, D. micans, &c., D. rhodostoma, and others, sphagnum-moss alone is recommended. Young seedlings also grow stronger and more freely in moss than in peat. Recently-imported pseudo-bulbs should at first be placed in crocks only, and kept in the Cattleya or intermediate-house until growth commences, when they may be potted and placed in a warm, genial atmosphere. The more delicate plants, and those of a very early set, newly-imported *Dendrobiums*, because if the roots get into a mass of sodden compost they speedily decay. For the first few weeks after re-potting or top-dressing, water must be supplied with unusual care, merely sprinkling the surface of the compost occasionally to induce the sphagnum-moss to grow moderately. When the roots have obtained a firm hold of the soil and around the inside of the pot, the amount of water may be gradually increased. As the young growths progress, syringing the undersides of the foliage very lightly with tepid rain-water at clearing time, on warm sunny afternoons. Instead of watering *Dendrobiums* in the morning, as is generally recommended, we always commence to water those that

require it at about 2 P.M. When this operation is completed, the plants are slightly dowed with a fine syringe, the blinds are then drawn up, and the plants exposed to the full afternoon's sunshine. By such practice the plants during the evening and the cool hours of the night absorb sufficient moisture to carry them safely through the heat of the following day; but if they were watered on the morning of a hot, drying day, the surface of the compost becomes as dry as dust by noon, and it is impossible then to tell whether they really are wet or dry. Such species as *D. balsamicum*, *D. embricatum*, *D. Paxtoni*, *D. moschatum*, *D. calceolus*, *D. clavatum*, and *D. Brynerianum*, are now showing their flower-spikes, and should be afforded more water at the root. The evergreen species, including *D. thyrsofolium*, *D. densiflorum*, *D. Farmeri*, *D. Schodereri*, *D. Griffithianum*, *D. aristatum*, *D. Gmbertianum*, and *D. chryso-toxum*, are also producing their flower-buds, and will now require a warmer atmosphere than their resting-quarters, and a little extra water at the root. *D. Benoniæ*, *D. Parishii*, *D. rhodopterium*, *D. nobilem*, *D. pulchellum*, and others that flower later on, must still be kept quiet until their flower-buds are well advanced.

THE HARDY FRUIT GARDEN.

By H. W. WARD, Rayleigh, Essex.

Disbudding and Training of Young Growth.—The disbudding and training of young growths being a very important and pressing cultural operation, should have almost daily attention. Hence the reason for reiterating the remarks I have made in previous calendars. The disbudding of the Peach and other fruit trees sufficiently advanced in growth to admit of this being done forthwith, should be finished, so as not to unnecessarily waste the forces of the trees by deferring the operation till the shoots have reached several inches in length before removing them. In disbudding a tree the lateral, or those shoots which arise from the sides of the branches, should be reserved for affording fruit next year, and these growths should be laid in equi-distant, when possible, between the branches from which they spring. This job is readily done with the straight twigs of the Birch, Hazel, Privet, &c., or the weak prunings of fruit trees, or if the twigs be wired they may be tied with raffia or bast, which latter should be loosely tied, so as to afford room for increase of growth in the shoots.

Blight.—Keep a watchful eye on green and black aphids, which, if neglected, rapidly overrun the shoots, doing much harm by sucking the juices of the tree, and defiling the foliage with excrement. On the insects being noticed, the foliage should be washed with the XL All insecticide, or tobacco-juice and clean water. The proper proportion of the XL All is 1 to 30, and that of the latter 1 to 10 or more, according to the strength. The insecticide should be used in the early morning, or in the afternoon after the sun has gone down.

Mildew.—The foliage of the Plum, Peach, Vine, &c., is sometimes affected, when young, with a species of mildew (*Sphaerotheca pannosa*), and weakly trees are more liable to become affected than such as are vigorous. The mildewed leaves should be dusted when damp with flowers-of-sulphur. A somewhat similar mildew attacks the Apple, against which the same means must be employed.

Blistered Leaves are sometimes caused by a fungus (*Exoascus deformans*) and by aphides. The crippling is very common on the affected leaves, and should the shoots, should be cut off, and burned forthwith, and the trees dressed with sulphur and an insecticide. With warmer weather the trees will gradually recover, but it should never be neglected, as it has the effect of spoiling the fruiting-shoots of the next year; moreover, the spores remain to commit similar injury the following year.

PLANTS UNDER GLASS.

By G. H. MAYCOCK, Gardener, Luton Hoop Park, Luton.

Poinsettias.—Old plants will now be showing signs of returning activity, and as soon as it is too early yet should to propagate the necessary quantity of plants, they should be placed in such a position that good healthy cuttings may be formed. Keep the plants dry at the roots for the present, and afford plenty of air and a moderately cool atmosphere. Next month the first batch of cuttings may be taken, removing them from the stock with a heel attached when not more than 2 inches long. Insert the cuttings in a compost of sand and leaf-mould in equal proportions, and place them under

a bell-glass in the propagating-house, in a bottom-heat of 70° to 75°. Batches of cuttings may be struck as desired until the end of June.

Lilies.—Balls of *Lilium auratum* and *lanceifolium*, that were potted up about the end of the year and plunged in cold frames, require attention at this date. Maintain a moist atmosphere day and night, and afford ventilation sparingly during the present cold weather, always closing early in the afternoon. Maintain a minimum temperature of 70° by night and 75° by day.

The Stove.—Examine recently-potted *Anthuriums*, and replace with live sphagnum-moss any of that has failed to grow. Keep the plants in a shady position in the stove. The new roots having taken a firm hold of the fresh material, water may be given them freely. If the plants are on a stage above hot-water pipes, some moisture-holding substance may with advantage be placed underneath the pots, such as peat-moss, which, if damped each morning, will prevent the plants becoming dry so frequently. The moss, however, must be frequently examined for slugs. Dip and sponge the leaves of *Dracenas* and *Codiaeums*, in a well prepared insecticide, doing this once a fortnight. A petroleum cask sawa through the middle makes a useful vessel for dipping purposes, providing a handle be placed on each side to render it more easily moved. Train the growths of stove-climbers before they become entangled. If there is a bed of fermenting materials in the stove, it should be wholly or partially renewed with new. When this has been done, re-plant the plants in it up to the rims of the pots. *Lilium auratum* balls should still be kept in cold-frames, and the lights made use of during rainy weather. The potfuls of *L. lanceifolium* and *L. l. album*, *L. tigrinum*, and similar species, may be plunged in coal-bashes out-of-doors in some sheltered position. Rain is not so injurious to these as to *L. auratum*; the stems should, however, be made secure against the wind. Any plants of *L. longiflorum* still in cold frames may now be placed in heat of 55° to 65°, if it be wished to forward their flowering.

General Work.—If more room be required in the houses, any plants of *Richardia* that have passed out of flower may be removed to a cold pit or frame, where the supply of water at the roots should be decreased. Move into the forcing-house more plants of *Spiræas*, *Spiræix*, *Hydrangea paniculata*, *Gladious Colvilleæ*, &c.

THE FLOWER GARDEN.

By CHARLES HERBIS, Gardener, Droppiers, Maidenhead.

Renovating Lawns.—The formation and renovation of lawns by the sowing of grass-seeds should be done during the present month whenever the soil is in a fit condition to bear for working upon. Before sowing, the land should be levelled, and well raked with long-toothed iron rakes, which is an important step, and the seeds made thoroughly firm, first trampling it, and afterwards by rolling both before and after sowing. Bare spots on lawns may be slightly forked-up, be given a sprinkling of fine rich loamy soil, raked over, and beaten with a spade or turf-beater, or rolled. Then sow the seeds fairly thickly to ensure a good turf being formed quickly.

Perennial Phloxes.—For providing a late display of these flowers, cuttings should now be inserted in sandy soil in 60-sized pots. Place them in a frame on a mild hot-bed, and shade from bright sun, when roots will soon form, and the plants, after being hardened off, may then be planted in the borders. Spring-streak plants will produce good flowers in bloom, and the older plants have passed out of flower. If the old clumps in borders have become very large, they may be split up with a spade into a convenient size, and replanted. This is a ready means of increase, but the heads of bloom are usually not so fine as those produced from plants raised from cuttings.

Michaelmas Daisies.—Plants obtained by pottling up small portions from the outside borders early in the season should now be in a good condition for planting out. Large beds filled with one or more varieties have a fine effect in the autumn, and, provided there are usually some old beds or borders that may be filled with these to advantage. Such varieties as *A. Anselm major*, *A. Robert Parker*, *A. Nancy*, or *A. Harpur Crowe*, and many others, when planted in a mass, make an acceptable change from other forms of bedding.

Daffodils in semi-wild gardens or in grass land where the bulbs cannot be conveniently found for removal after the tops have died away, may be transplanted with care after the flowering is over.

In such a position, however, Daffodils need be rarely disturbed. When moved at this date, the bulbs should be lifted and divided with as little breakage of the roots as possible, and be replanted immediately. Instead of pulling the clumps in pieces and separating the smaller bulbs from the larger, simply break them into small clumps, and plant altogether. If the staple be poor, some of it may be thrown out to allow of a good shovelful of new compost being used for planting in. The bulbs should be placed 3 inches below the surface. Daffodils and other bulbs, as *Scillas*, *Crocuses*, *Hyacinths*, &c., that have been forced in pots should be gradually hardened off and afterwards planted out in some portion of the grounds in the vicinity, if not directly, under deciduous trees. Such spots, and many other nooks, may be made beautiful in spring by utilising all spare bulbous subjects in this way.

THE KITCHEN GARDEN.

By W. POPE, Gardener, Highclere Castle, Newbury.

Turnips may now be sown more freely. For summersowing, Veitch's Red Globe and Snowball are good varieties. Where tall-growing Peas have been sown sufficiently wide apart to admit of a crop being taken between the rows, Turnips are suitable for the purpose, as the slight shade afforded at certain portions of the day tends to keep the land in a cool and moist condition. From the middle of May until the middle of July sowings are best made on a border with a north aspect, a few rows being sown about once a fortnight, to ensure a constant supply of tender roots during the dry, hot days of summer.

Spinach.—The present is a good time to increase the stock by division of the clumps. This ought to be done at least once in three years, for if left too long in the same place the leaves are apt to dwindle in size, and the plants throw up seed-stems very early in the season. I find there are two varieties differing greatly in the size of leaf, and the proneness to rush up to flower. Plant in an open position in rich soil. When seed-stems are produced in the summer, cut a portion of the plants over entirely, and as soon as they have thrown a fresh crop of leaves, cut over the remainder, and thus insure a constant supply.

Saladry and Scorzenera.—Sow a few rows of each of these rich, deeply-dug soil; the variety of Saladry known as the Giant is preferable. The land should be prepared as for Carrots, Parsnips, &c., and free from recently-applied manure, the rows being 15 to 18 inches apart, and the plants thinned early to 8 inches apart in the rows. If sown too early flower-stems are likely to be produced, more especially in the case of Scorzenera.

Main Crop and Late Broccoli.—These should now be sown preferably in shallow drills on fairly rich soil. Narrow borders by the side of kitchen garden paths are sometimes chosen, being convenient for affording protection from birds, and handy for drawing out the plants when required. They require an open sunny site, and the seed may be sown in drills 9 or 10 inches apart, taking especial care to sow thinly. Some good kinds for succession are Veitch's Self-Protecting Autumn, Sutton's Michaelmas White, Snow's Superb Winter White, Sutton's Vanguard, Christmas White, Early Penzance, Veitch's Main Crop, Sutton's Safeguard, Veitch's Model, and Sutton's Late Queen. The plants must not be allowed to remain in the seed-beds long enough to become drawn and leggy. If the land is not likely to be ready for the reception of the plants they are large enough to be thinned out, the best plan will be to prick-out a sufficient quantity of each variety on a properly prepared border 5 or 6 inches apart each way, which will give each plant room to develop, and will somewhat check their growth for a time, and tend to keep them dwarf and sturdy.

Kidney Beans.—A few rows of dwarf Kidney Beans of the No Plus Ultra type may be sown on a warm and sheltered border, where coverings can be applied for a time if necessary.

"FARM AND GARDEN INSECTS" Under this title, a useful little book has been prepared by Dr. SOWERBY, which, while partly devoted to the anatomy of insects in general, deals also with many well-known pests particularly, and gives brief directions for coping with them. The volume contains many illustrations, and it may be commended for carrying in the pocket on occasions where more ambitious works are not portable. (The publishers are Messrs. MACMILLAN & Co., London and New York.)

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on ONE SIDE ONLY of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction in these pages, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, APRIL 24—Royal Botanic Society's Meeting.

SALES.

WEDNESDAY, APRIL 21—Border Plants and Bulbs, Lilies, Roses, Shrubs, Trees, &c., at Mr. Stevens' Rooms.
Japanese Lilies, Liburn, Earlish, Azalea, Palms, Ferns, and Carnations, at Protheroe and Morris' Rooms.
FRIDAY, APRIL 23—Orchids from Messrs. F. Sautler & Co., at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—49°.

ACTUAL TEMPERATURES.—

LONDON.—April 15 (6 P.M.): Max., 55° to 60°; Min., 47°.
PROVINCES.—April 13 (6 P.M.): Max., 55°, York; Min., 42°, Aberdeen.

THE DEBATE in the House of Commons on Friday last relating to the earlier opening of Kew Gardens was not only amusing, but rather more pertinent than usual, inasmuch as there were among the speakers some like Mr. CHAMBERLAIN and Mr. HERBERT GLADSTONE, who really know something of the work that is done at Kew, and of the means that may be taken to facilitate or to impede it, as the case may be. The majority of the speakers, as of those who make the demand for earlier opening in general, are either persons whose claims to consideration are not to be considered in comparison with the inconvenience that would arise from the concession of their demands, or they are persons who are not aware of the privileges that are already accorded to any one visiting the gardens for purposes other than mere sight-seeing or recreation.

A great deal has been done in the way of popularising Kew of late years, restrictions have been removed, and much more labour and money have been expended on decorative gardening than was formerly the case, and that this is highly appreciated by the public there can be no manner of doubt. The exclamations of the visitors to No. 4 house, which is always attractive, and just now specially so, are only comparable to the ejaculations heard at a fireworks display! Equally remarkable is it to find that many of the visitors, or some of the

visitors' friends, have "got that at home," the "that" being something not improbably almost unique! It is most desirable that this description of spectator, which forms numerically the largest class of visitors to Kew, should have ample facilities for seeing everything there is to see, and that aid should be given them by the free use of descriptive labels, and where possible by the adoption of a system of "personally-conducted visits."

But whilst every reasonable facility should be accorded to the sight-seer, it is clear that the more serious interests of the garden and its administrators must not be sacrificed for any such purpose. Time must be found for sweeping and garnishing, operations which, as every proprietor of a greenhouse knows, cannot adequately be performed in the presence of visitors.

Another point which has not been sufficiently considered, is the convenience of the administrators. The daily work of inspection, supervision, and administration generally, must be very heavy, and a large portion of this must, of necessity, be done before the entrance of the public renders it more or less impracticable. Are the administrators to be expected to take lanterns and accompany the night watchmen on their rounds? The only persons, indeed, who can judge whether earlier opening is practicable are the administrators and those responsible for the varied work of the garden. Everyone would be glad if they could see their way to an earlier opening, but in view of the facilities offered to gardeners and students generally, and especially in view of the extent and importance of the work done for the benefit of home and colonial cultivators, we should deprecate any change that would interfere in any degree with the scientific and practical work of the garden. Kew, it must always be remembered, is Kew, and not a park.

The practical nature and objects of the Kew establishment require, it would seem to be instilled into the minds of the residents who are anxious to see Kew a recreation-ground pure and simple, and who are even advocating in a local journal the introduction of "mail carts" and perambulators. As the writer proposes to proceed by degrees, we suppose, having obtained access for the mail carts, an agitation will be set up for the increase of the attractions by the performances of nigger minstrels and the like. By the time that that innovation is accomplished, the more strictly botanical part of Kew will have to be transferred into purer air in the country, far from the smoke and smells of Brentford, and "away from the crowd, the hum, the shock of men," and Kew can then be given up to perambulators and mail carts.

We take what follows from the columns of the *Times*—

"MR. BURNS (Battersea) appealed to the First Commissioner of Works to reconsider his decision not to open Kew Gardens to the public at an earlier hour than 12 o'clock. He hoped he should have the support of the Colonial Secretary in this matter, for he had seen parties of colonial visitors, Americans, Frenchmen, Germans, and others, in consequence of the present regulations, either to kick their heels about on the river-side for perhaps a couple of hours or to go away and miss the opportunity of seeing the gardens altogether. It was absurd to suppose that, owing to pure 'cussedness' on the part of the permanent officials, who wished that the students should have privacy, this magnificent public institution should be closed until 12 o'clock in the day.

MR. CHAMBERLAIN did not see the object of the interruption. The hon. gentleman sat down, having just appended to the right hon. gentleman the First Commissioner of Works to protest against the 'pigeahedness' of those who were administering Kew Gardens.

MR. BURNS: Pure 'cussedness.'

MR. CHAMBERLAIN: 'Pure cussedness!' That was, perhaps, worse. Cussedness implied some control, whereas

a man might be born pig-headed. But he rose, in answer to the hon. gentleman's appeal, to join him in his attack upon the administration of Kew Gardens. The hon. gentleman had appealed to him as Colonial Secretary only, but he might have appealed to him as a very enthusiastic horticulturist, for he could certainly say that to him gardening was even a greater delight than politics themselves. The hon. member had failed to realise the peculiar position in which Kew Gardens stood; he treated them as if they existed for the benefit of the inhabitants of Kew, that was not the proper merit or claim the gardens had upon the support of the Committee, but it was as a great scientific establishment. We were very justly proud of the gardens. He had seen almost every botanical garden in Europe, and he thought he was right in saying there was nothing in the whole of Europe that could hold its own with Kew. That was not owing so much to the decoration of the gardens, but as to their scientific value. The hon. gentleman said that French and German people had to wait outside the gates, having got there before the time of opening; and he complained of the "cussedness" of officials because they did not give the gates before the proper time. That was really a little too absurd. If one went at 11 o'clock to an institution in France which opened at 12 o'clock it was his pigeahedness, and not the pigeahedness of the officials, which kept the doors closed. There was nothing peculiar in Kew Gardens opening at 12 o'clock. A great number of officials because of the great improvements made in the Mauritius, and some of the West Indian Islands were due almost entirely to the advice and assistance received from the Kew officials—the gentleman whom the hon. member had described as pigeahed or cussed. It was not fair to attack public servants who were performing their duty, and it was not fair to throw on them for the benefit of children and nursery-maids, and Frenchmen and Germans, duties which would detract from their value as advisers of the colonial and other officers of the Government who might from time to time have occasion to apply for their services. He thought that, on consideration, the Committee would see that the public were opened every weekday at 12 o'clock, and on Sunday afternoon, which was, after all, the most popular time, and when Kew was visited by the largest number of people.

MR. GLADSTONE (Leeds, W.) said that his hon. friend (Mr. Burns) was fully justified in bringing this point before the notice of the Committee. It was desirable to extend the privilege of visiting Kew Gardens to as many people as possible; but the question was not so simple as his hon. friend proposed. Of course, sometimes, when pressure of this kind was brought to bear on public offices, a way was found to meet the suggestions that were made. But, as in this matter, he had gone into it fully when he was First Commissioner of Works, and he found that when the gardens were opened on Bank Holidays at an earlier hour than 12, comparatively few people availed themselves of the privilege. He did not think that sufficient advantage would result from this arrangement to warrant the extra cost which would be involved. But it might be possible to give more facilities to societies and students to visit the gardens under special permission.

MR. AKESS-DOUGLAS said that there could be no doubt that arrangements might be made in that direction. He had made special inquiries, and he found that anyone wishing to visit the gardens early for scientific purposes was never refused admission. If institutions, such as the hon. member for Battersea had mentioned, wished for the purposes of study to visit the gardens he was sure that they would be admitted, and more than that, he would take care that they should be admitted.

MR. BURNS said that he was much obliged for the courteous and valuable concession which the right hon. gentleman had made.

MR. AKESS-DOUGLAS.—It is not a concession, because the privilege is granted already.

A CHRYSANTHEMUM AS GROWN IN JAPAN.

Our illustration (fig. 85) represents an example of Japanese culture which would not be readily excelled by our best cultivators of the Chrysanthemum. In form it does not appear to differ from those we are accustomed to observe at the big November shows in this country, although in size and in the number of the flowers it greatly exceeds them. The height of the specimen measured 6 feet 6 inches; width, 9 feet 9 inches in one direction, and 13 feet in the other. Each stem carried a single flower, of which there were 800, and the plant possessed only one stem. It was a seedling variety raised by Mr. H. FUKUCHI, and grown in Tokio in 1896 by Mr. ITOHAKAWA, under the directions of the raiser.

FIG. 53.—A CHRYSANTHEMUM AS GROWN IN JAPAN. (SEE P. 254.)

LINNEAN SOCIETY.—The next meeting of this society will be held on Thursday, April 15, at 8 p.m. precisely, when the following papers will be read:—Mr. H. FISHER, "Preliminary observations upon plants collected during two years' residence in Franz-Josef Land." Mr. A. O. WALKER, "On some new Irish Crustacea." Messrs. W. & G. S. WEST, "On Desmids from Singapore."

THE FLORAL COMMITTEE.—The subjoined letter raises a question which has often been mooted, but never been satisfactorily arranged. No better or more impartial tribunal could be found to adjudicate upon florists' flowers, flowers of a purely decorative character, and flowers wherein commercial considerations are directly involved, than the Floral Committee. It is otherwise with new, or comparatively new plants, or old plants of botanical interest not yet widely distributed in commerce, or among amateurs. These receive but scanty attention on the part of the committee, or perhaps may be passed over entirely. The *Chionodoxa* was a flagrant instance, but that is now ancient history. A more recent case, when a plant of the original wild Chinese *Primula*, a plant one would think of the greatest historical interest to lovers of plants, was passed over by the Floral Committee without any public award being made, though it is true, for the credit of the Society, that the omission was afterwards remedied. The "Botanical Certificate," instead of being looked on as something to be given to some plant not sufficiently attractive to merit a First-class Certificate, should be granted to plants of historical and botanical interest, and should be treated as of at least equal importance, in its way, as a First-class Certificate; or rather, considering the freedom with which the latter are awarded, as of much greater value. At the Orchid Committee a Botanical Certificate is often granted to some plant the "botanical" importance of which the great majority of the voters are, we fear, not in a position to appreciate. The only reason for the bestowal of this award is that the plant is not of a decorative character!

TULIPA KAUFMANNIANA.—I do not know on what grounds the Floral Committee of the Royal Horticultural Society gave a First-class Certificate to a plant shown under this name by Messrs. Barr & Messrs. Wallace at the last meeting of the society. If your figure 72 is a correct representation of it, it is not at all the best form of this beautiful plant, which I have grown for at least eighteen years, and which I have more than once exhibited at the Society's meetings without any notice being taken of it. Your remark on p. 217 as to the astonishing difference between the plant as now shown and the plant figured by Regel, confirms me in this impression, as does your description of its colour, which you say is variable from pale pink to pale rose-purple. In the *Journal of the Royal Horticultural Society for 1879*, vol. v., p. 202, you will find some "Notes on the Genus Tulipa," in which I spoke of the plant as follows:—"This very lovely Tulip is one of the earliest in flower, and at the same time one of the most beautiful of its section. The flower is developed in advance of the leaves, which, at the time of flowering, are quite short, and of a pale glaucous green. The colour is bright carmine outside, deepest on the outer segments, which are bordered with a white. The inside is nearly white, with a bright yellow centre, and a band of carmine above this. The flower opens quite flat in the sun, and is about 3 inches in diameter. A Tulip resembling this in all but colour flowered at the same time, and is probably a variety of it. It is deep Primrose-yellow, with golden centre and anthers, and if not already named by Dr. Regel, may be called after him." I sent the first form of the plant shortly afterwards, but have since retained and increased the other yellow form, both by seed and offsets, and have given it to many friends, so that it should by now be a well-known plant. Though I have often remarked the general tendency of wild Tulips to alter their characters in cultivation, this plant has remained comparatively constant during eighteen years, and preserves its colour and extreme earliness, though somewhat larger in size. I have not the slightest reason to object to its receiving a First-class Certificate because it is an old plant, but I do object to an inferior form receiving one when the best form has been ignored. The Floral Committee of the present constitution is not a competent tribunal to judge of the merits of many plants brought before it. I will remember a leading member of the committee telling me many years ago when I first exhibited *Chionodoxa Lucella*, that it was a trumpery plant, no better than, if as good as, the common wood Hyacinth. Last month I sent a plant which (as the credit of producing it is not due to myself, but to my friend MAX LECHNER) I may say was a triumph of good cultivation, and which has, so far as I can learn, never been shown in such good condition before, namely, *Lilium Thompsonianum*, to the committee, who ignored it, for what reason I cannot say, for though an old plant, it is, when

properly grown, a very beautiful one. The fact seems to be, that the number of purely florist flowers is now so great, and the knowledge of a majority of the members of the Floral Committee so much confined to them, that it is just as impossible for them to judge the horticultural qualities of a botanical species, as it would be ridiculous for me to judge the qualities of a Phlox or a Gladiolus. I would therefore suggest to the council that the committee should be divided into two sections, one for florist's flowers, and one for plants which have not as yet been improved or hybridised to such an extent that their original characters, &c., have been lost. H. J. EVANS, *Colborne Park, Gloucestershire*."

KEW.—In No. 1 house, devoted principally to Aroids, *Amberstia nobilis* is now in bloom. Unfortunately the flowers are at the top of the tree, where their beauty and singularity cannot be seen. The grass in places is converted into a perfect sea of Daffodils—an exciting display. In No. 4, the show-house, *Rhododendron Sesterianum* is in full bloom, and quantities of a very effective early-flowering form known as *Rosy Bell*. *Anaxias*, *Lilacs*, *Cytisus*, *Hippocastanum*, *Spirea*, *Van Houttei*, *Cineraria cruenta*, and countless other things combine to render the house attractive. The Alpine-house, No. 24, is perhaps less interesting than usual, but there are numerous *Muscicis*, *Irises*, *Primulas*, *Auriculas*, and such like to charm the visitor. The rockery is, as usual, full of interest; a patch of *Primula rosea*, planted in a marshy nook, is very effective. Kew will form a delightful place for a visit in the Easter holidays.

YORKSHIRE NATURALIST'S UNION.—The excursions and meetings that are arranged to take place this year are:—April 19 (Easter Monday), Boston Spa; Thursday, May 13, Skelmanthorpe; June 7 (Whit Monday), Cothelstone; July 8, Thursday, Scarborough and Hackness; August 2 (Bank Holiday), Monday, Everingham Park. The autumn meeting at Earnsley for a Fungus Foray, the date will be fixed later; and the annual meeting will take place at Darlington on Wednesday, November 24. The honorary secretary is Mr. W. DENISON ROBERTS, Sonny Bank, Leeds.

BOTANICAL MAGAZINE.—The plants of which coloured plates and descriptions are given in the April number are:—

Agave Hasdefii.—A Mexican species, which flowered at Kew in 1895, and was described in our columns by Mr. BAKER, 1877, p. 653.—t. 7527.

Gentiana tibetica.—A robust Himalayan species, with broadly-lanceolate leaves and tufts of purple flowers, with the short lobes of the corolla greenish-yellow, and thickly spotted. Kew. The plant grows in Chumbi, on the Tibetan border, between Sikkim and Bhotan, a region remarkable for its dry climate. Europeans are at present jealously excluded by the Tibetans, but native collectors have been employed successfully in obtaining seeds, &c., by Dr. KING; t. 7528.

Tristania laurina, R. Br.—A shrub or low tree of the Myrtaceae family, with lanceolate leaves, paler on the under surface. Flowers numerous, small, yellow, in axillary clusters. Kew; t. 7529.

Gonypora tricolor, Rehb. f.—A species from Costa Rica, with ovoid, ribbed pseudo-bulbs, broadly ovate lanceolate leaves, and racemes of reddish spotted flowers. Kew; t. 7530.

Suaeda Smithii.—A noble herbaceous plant, native of South Chile and Faegia, and hardy at Kew, where it attained in an open border a height of 3 feet. The stems are herbaceous; the leaves are stalked, ovate, oblong, covered with araceous hairs, and bearing terminal corymbs of white flower-heads, each about 1 inch across.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held on Monday, April 26, when a paper will be read by Mr. W. H. PAYNE (Barrister-at-Law, L.C.C.), entitled "Local Authorities and the Building Laws." The chair to be taken at 8 o'clock. In consequence of the Easter holidays, the Institution premises will be closed from Thursday evening, the 15th inst., to Wednesday morning, the 21st inst.

ARBOR-DAY.—When, in our last issue, we alluded to the wasted opportunities afforded by bare walls,

we were not aware that a gentleman at Hoxtable near Swanley had put our precepts into practice by presenting to each one of sixty approved cottage-residents a Vine. The Vines supplied by Messrs. BUNYARD were the Sweetwater. The donor, who prefers to remain anonymous, has offered four prizes of £1, 15s., 10s., and 5s., to the cottagers who produce the heaviest amount of ripe fruit. Six Vines of the same description were presented to the six "Homes for Boys."

GARDENERS' ROYAL BRANCH INSTITUTION (*Horwester and District Benevolent*).—By permission of EARL BRITCHEAM, the president of the branch, the gardens at Madresfield Court, his lordship's Worcestershire residence, will be thrown open to the public on Thursday, April 22 next. The charges for admission are from 2 till 5 o'clock, one shilling; and from 5 till 7 o'clock, sixpence, the proceeds being given to the above excellent institution. The spring flowers at Madresfield Court will be in perfection about the above date.

THE MIDLAND DAHLIA SOCIETY AT WELLINGBOROUGH.—This Society, which has grown out of a Dahlia exhibition held here in September last, was inaugurated on Friday, the 9th inst., when Mr. R. DEAN delivered a lecture on the Dahlia, its history, types, cultivation, &c., before a considerable and interested audience. The chair was occupied by Mr. T. PENFRED, the President of the Society, who announced that the prospects of the Society were most encouraging, and that there was every probability that an excellent display of Dahlias would be held on September 11 next.

PRESENTATION.—Mr. A. GRAHAM, the late superintendent of the Royal Park and Gardens, Hampton Court, was on Wednesday, 7th inst., presented by a number of his friends with a pair of silver-plated entrée dishes and a purse of money, together with an illuminated address on the occasion of his retirement from the position he has held for a period of more than twenty years. Advantage was taken of the occasion to present to Mrs. GRAHAM a gold watch, the gift of an anonymous donor. The presentation was made by Mr. R. M. BONIWELL, and Mr. GRAHAM suitably replied on his own and Mrs. GRAHAM's behalf.

"LE CHRYSANTHEMUM."—This little periodical, published by the French National Chrysanthemum Society, continues to make its appearance regularly every month, although it was originally intended to be a quarterly. The April number is just to hand, and among its contents we notice an able article by Mr. COILLARD on the subject of the alphabetical arrangement of *Chrysanthemum* names, in which he, as registrar of the Society, takes a particular interest. The secretary's report, some remarks in reply to Mr. FALZUS's complaint at the use of English technical terms when good French ones already exist, and a first instalment of the report of the deputation of the English National Chrysanthemum Society to the foreign shows, also appear.

READING GARDENERS' ASSOCIATION.—The closing meeting of the spring session of the Reading Gardeners' Association was held on Monday evening, the 12th inst., in the Club Room, British Workman, when Mr. C. B. STEVENS presided over a large attendance of members. The paper for the evening was "Zonal Pelargoniums," by Mr. H. SHOESMITH, Clarendon Nursery, Woking. The paper was of an exceedingly practical character, being full of plain cultural notes, and was followed by the members with the closest attention. In introducing his subject, the lecturer said he had selected one that had been somewhat neglected at horticultural meetings, although it was not a new one. The lecture touched upon the propagation of the plants, the kind of soil necessary to obtaining good bloom, the propriety of using pots of comparatively small sizes for ordinary decorative purposes, the need of firm potting, winter treatment, diseases to which the zonal Pelargonium is liable; and giving, at the conclusion, a list

of varieties, of which we may mention the following:—For general culture, single varieties: A. F. Wootton, Cassiope, Duchess of York, Dr. Rawson, E. Bidwell, Enid, Geo. Gordon, Kitty, Lord Farrer, Madame Jules Clévia, M. Calvat, Mr. Owen Thomas, Mrs. Hall, Olivia, O. W. Holmes, Pink Domino, Phyllis, Rev. Bartrum, Royal Purple, Trilby, T. W. Lawton, Wilhelmina, Souv. de S. B. Miller, W. Bealy, Virginia. Double varieties: Annie Henriot, Beauté Poitevine, Gustave Emich, Golden Gate, Joyful, Madame Charlotte, Raspail Improved, Her mine. For winter flowering, the following are the best:—Singles: Albion, Amy Amphlett, Chas. Mason, Edith Strachan, Eoid, Kitty, Mille. Trine, Olivia, Pink Domino, Ploema, Rosy Morn, Stella Massey, Volcais, W. Bealy. Doubles: Double H. Jacoby, Gustave Emich, Hermoine, Raspail Improved, Beauté Poitevine. Many questions were asked, and an animated discussion took place.

INDIAN COTTONS.—Mr. T. H. MIDDLETON has reprinted from the *Agricultural Ledger* (Calcutta) a valuable article on the cultivated Cottons of India. Mr. MIDDLETON has cultivated some sixty or seventy varieties from different parts of India, and compared them when growing. In the pamphlet before us he describes most of the varieties. Mr. MIDDLETON follows the classification of TOMARO, but considers that the Italian botanist made too many species. Mr. MIDDLETON himself accepts G. herbaceum, G. arboreum (in hybrids only), G. roseum, G. indicum, and G. neglectum; G. indicum being a marked variety of herbaceum, and G. neglectum a hybrid. Of G. Stocksii, described by Dr. MANDERS, and considered by him as likely to be the origin of G. herbaceum, Mr. MIDDLETON says, "I believe its nearest relative to be G. herbaceum."

FLORA OF THE ALPS.—Mr. J. C. NIMMO announces the publication, in eight monthly parts, of Mr. ALFRED BENNETT'S *Flora of the Alps*—a useful book for those intending to visit Switzerland.

NEW DWARF LANTANAS.—Having succeeded in fixing the habit of a number of dwarf varieties of Lantana, M. BRUNET, Poitiers, is bringing into commerce the following:—Fabiola, rose-coloured; Stahl, large flower, of an orange colour, which takes on a reddish tinge with age; Muse, very large flower, very margin, a butter-yellow, the centre shining yellow, and later of a sunnise tint, edged with rose; Cinnia is valerian-red; F. Fournaise, flowers and corymb large, and the colour a fiery Nasturtium-red. These varieties should form capital material for planting beds in warm sunny localities.

FUCHSIAS.—To MESSRS. CANNELL & SONS we are indebted for the inspection of specimens of a new Fuchsia, called "Addington," said to be a hybrid between *F. fulgens* and *F. splendens* var. *cordifolia*. The plant is evidently very free flowering, and softly pubescent on the surface. The leaves are shortly stalked, ovate-lanceolate. The flowers are very numerous, on drooping pedicels, each about 2 cent. long (about $\frac{3}{4}$ inch). The ovary is slender, 1 cent. long; the calyx tube 3 cent. long (say $\frac{1}{2}$ inch), cylindrical, rosy-red. The lobes of the limb are reflexed, 12 mill. (about $\frac{1}{2}$ inch) long, reflexed, lanceolate. The petals are deep rose coloured, ovate-roundish, about the length of the calyx-lobes. It would apparently make a first-rate variety for growing on the rafters of a greenhouse.

GRAPES FROM THE CAPE.—We have this week to note the arrival of the steamships *Dunottar Castle* and *Trojan*, from the Cape of Good Hope, the former with 470 boxes of white, and 40 boxes of black Grapes; the latter with 383 boxes of white Grapes. As to condition, the reporter says:—"The consignments of the *Dunottar Castle* turned out in good condition, particularly the black Grapes, and fair prices were realised. The consignments per the *Trojan* turned out in fair condition, and realised fair prices."

STOCK-TAKING: MARCH.—On the 31st ult. the national stock-taking for the year was brought to a close, and on the following day the revenue account was issued, and may be given in brief—so far as we are concerned here—as follows:—Total revenue, £12,198,547; in the year 1896, £109,339,946; a difference in favour of the year just ended, £2,858,591. The figures are astounding, and as to the surplus, perhaps the Chancellor of the Exchequer is a happy man. The increase in duty-paying articles of food and drink is very noticeable, but the Board of Trade returns, month by month, have prepared us for all this, and those for the month just ended, and now to be noticed, afford ample verification of the statement. Now, as to the imports for March: these amount to £40,555,114, against £38,366,750—an increase of £2,288,364. In the various sections, only three "decreases" are noted, i.e., of £92,515 in "animals. living for food;" of £104,815 in "oils," and of £15,852 in "the parcel post." All classes of food and drink are in excess, with the exception of Wheat, which shows an enhanced value for a reduced quantity imported. Sugar is also in the minus section. Raw materials for textiles have a large increase to place on record here and there; though cotton from the United States showed a large falling off. Our usual extract from the "summary table" is as follows:—

Imports.	1896.	1897.	Difference.
Total value	38,366,750	40,555,114	+2,288,364
(A.) Articles of food and drink—duty free	12,142,294	12,947,692	+41,398
(B.) Articles of food and drink—dutiable	2,155,024	2,363,448	+404,824
Raw materials for textile manufactures	7,091,403	7,587,037	+495,634
Raw materials for sundry industries and manufactures	4,302,295	4,384,580	+41,085
(A.) Miscellaneous articles	1,229,724	1,412,710	+18,586
(B.) Parcel Post	39,718	74,566	+15,852

Yarns have moved up, also silk manufactures; and generally, in the hope of a good time coming, a goodly show of imports under this special section are placed on the list. The imports for the three months of the year are valued at £117,833,863, against £112,317,342 in the same period last year—an increase of £5,516,521. Respecting fruits, roots, and vegetables, we make the accompanying interesting extracts from the general mass of figures:—

Imports.	1896.	1897.	Difference.
Fruits, raw:—			
Apples	170,938	618,243	+447,371
Cherries	"	"	"
Plums	17	6	-11
Pears	124	1,793	+1,472
Grapes	2,440	3,205	+777
Unenumerated	32,285	58,065	+25,780
Onions	288,705	301,052	+12,347
Potatoes	31,539	45,207	+13,671
Vegetables, raw, enumerated	414,141	4168,432	66,700

One remarkable feature in this table is the great supply of Apples, the estimated value of which is £152,798, and for the three months' supply the value is placed at £358,850. Our former friends and others might make a note of this.

THE EXPORTS

for the month are placed at £21,617,269, as against £20,419,623 for the same period last year—an increase of £1,197,646. The two sections showing a reduction are yarns and textile fabrics (£265,895), and apparel and articles of personal use (£39,637). However satisfactory this may be when compared with last month's report, still on the three months

there are some £2,092,022 to wipe off. Machinery for the manufacture of textile goods has gone off well to Japan, India, and Germany, and there is an increase of pigiron to the Continent. Strange to note, as in February, there is an increase in textiles to Turkey; and the output of railway materials—locomotives, rails, and rolling stock increased. "Metal manufactures" went up by £428,000, and telegraph wire shows an excess of £118,000. Mining machinery has little to record. Coal to the Continent went up £187,000, and wool by £147,000.

SCOTTISH HORTICULTURAL ASSOCIATION.

A large number of members of the above society met on Wednesday evening, April 8, at Dowell's Rooms, George Street, Edinburgh, Mr. TODD in the chair, to listen to Mr. A. CHALMERS' interesting paper, illustrated by lantern slides, of "A Trip through the Bulb-farms of Holland." The reader vividly and instructively put before his audience the methods of propagation, planting, and the chief points in their cultivation. A hearty vote of thanks was accorded Mr. A. CHALMERS. Some greenhouse hybrid Rhododendrons were exhibited by Mr. McMILLAN, Trinity Cottage, Edinburgh, the flowers of which were large, and of good substance, with prettily undulated edges.

PRESENTATION TO MR. JAMES DOUGLAS.

On the occasion of the luncheon partaken of by the members and friends of the National Carnation and Picotee, and the National Auricula and Primula Societies of the South of England, on Tuesday last, at the Hotel Windsor, Victoria Street, Westminster, Mr. JAMES DOUGLAS, who has for a great number of years been the secretary of each, was presented with a clock and a purse of 30 guineas on his resignation of his office.

PUBLICATIONS RECEIVED.

The Musical Home (SIMPKIN, MARSHALL, HAMILTON, KEMP & Co., London) contains a good selection of music and songs, classical and popular, some for advanced musicians, others for children.—*The World's Musical Life* (HORACE MARSHALL & SON, Temple Avenue, E.C.) contains no scores (such as will make the first-named journal welcome in every musical home), but is devoted to notes and chit-chat on music and musical matters.—*Offertenblatt der "Bienenkunst"* (Erfurt), an illustrated publication devoted to mounting and arranging flowers for bouquets, and every other sort of decorative purpose.—*Les Animaux Utiles et Nuisibles à l'Horticulture* (Insectes crepuscules), par A. LARBAETRIER. Another of that useful series of horticultural handbooks published by OCTAVE DOIS, Paris, in the Bibliothèque d'Horticulture et de Jardinage.—*The Amateur Photographer*, April 2. The letterpress and illustrations are excellent and varied.—*Agricultural Economist*, April 1, devotes a few pages to gardening, and contains much interesting matter.—*Pharmaceutical Journal*.—*The Canadian Horticulturist* (Grimsby, Ontario) for March.—*Bulletin of the Botanical Department, Jamaica*, December, 1896. This includes the annual report of the Director, Mr. W. FAWCETT, and the index to vol. iii. In the Educational Department, the industrial school is making good progress, and would advance further were the available premises larger. For the Herbarium, a specimen of Jamaican Satin Wood is much desired. It is said that "judging from the leaf only, it appears to be allied to *Amegris* and to *Nanthoënum*, but it is necessary to have the flowers and seed-vessels to determine it exactly."—*Annual Report for 1896 from the Royal Botanic Gardens, Trinidad*, by J. H. HART, Superintendent. The year's progress has been, on the whole, satisfactory, and we note, among minor items of news, that, from twelve seeds of the double *Coccoloba Palm* brought from the Seychelles rather early than a year ago, "two have developed a single leaf, and five others have commenced to show above ground."—*The National Nurseriesman*, April (Rochester, N. Y.).—*Annual Report of the Secretary for Agriculture, Nova Scotia*, records a prosperous season; contains notes from various agricultural societies, and articles on subjects relevant to the title.—1

Report upon the Grasses and Forest Plants of the Rocky Mountain Region, by P. A. RYDBERG and C. L. SHEAR (U. S. Department of Agriculture). A revision of the results of three months' collection and study in certain parts of Nebraska, Idaho, Montana, Utah, and Colorado.—*The American Florist*, March 20.—*Dictionnaire Pratique d'Horticulture et de Jardinage*. This, the 59th Livraison, includes the beginning of the notes upon ROSA.—*L'Horticulture Potivine*. This is a catalogue from the firm of BSAUNT, of Poitiers (Vienna), and includes pictures and descriptions of the plants and tools offered.—*Société Nationale d'Horticulture de France*. Liste générale des Membres de la Société, including a brief review of its existence (since 1826), notes on affiliated and corresponding societies, &c.—*Report on Natal Botanic Gardens* (Durban Botanic Society), by J. MEDLEY WOOD, Curator. This, the fifteenth annual report, mentions good work which might have been even better with more workmen, and a larger field for operations.—*Colonial Herbarium* (Durban). Report for 1896, by J. M. WOOD, Curator. The number of specimens in the Herbarium has been increased during 1896 by more than 1000 additions, and further development is continually expected.—*Wiener Illustrirte Garten-Zeitung*, March.—*Bulletino della R. Società Toscana di Orticoltura*, March.

THE SPECIES OF THUYA.

(Continued from p. 214.)

THUYA OCCIDENTALIS VAR. Plicata.—This is the plant commonly called, for brevity sake, *Thuya plicata*. The true *Thuya plicata*, as we have attempted to show, is the fine species now generally called *T. gigantea*. There are several seedling forms of *T. occidentalis*, *plicata*, in gardens, such as *cristata*, and it passes gradually into *T. occidentalis* var. *Wareana*, but almost all of these varieties show the flattened bead-like foliage and large glands of *T. occidentalis*. In some of the forms the dense masses of branches, the branch systems as they are called now-a-days, are concave and somewhat spirally curved, like the inner surface of the thread of a screw. The varied sweeps and curves of these screw-like scooped branches are very beautiful. One of the varieties of *Cupressus Lawsoniana*, that introduced by the late Maurice Young, has a similar appearance, and doubtless a similar disposition is not uncommon among seedling Conifers. In colour the foliage of *T. occidentalis* var. *plicata* is usually very deep green, and the central and lateral leaves are very regular and nearly equal in size. The cones, as may be seen from our illustration (fig. 86), are quite similar to those of *T. occidentalis*.

By some, as we have said, this form is considered to be *T. plicata*, Don, and is registered as a native of North-west America and East Siberia. This error as to the geographical distribution has arisen from the entanglement in the nomenclature not only of the plants, but of those who stood god-fathers for them, viz., James Donn and David Don. The true *plicata* is that now generally grown as *gigantea*, with a few other synonyms which it is well to forget or put aside as soon as possible. There is no *Arbor vite* or *Thuya* in Eastern Siberia, unless it be *Thuya* (*Biota*) *orientalis*.

Among the very numerous specimens of *occidentalis-plicata* that have passed through our hands of late years, there has not been one that could be referred to the Pacific species, but all to *T. occidentalis*.

Among the other very numerous varieties of *T. occidentalis*, mention must be made of *T. WAREANA*, Hort. For us this is a form of *T. occidentalis*, very closely allied indeed to *T. occidentalis plicata*, but usually more robust, and with larger foliage. Specimens in our herbarium correspond very closely with the native form of *T. occidentalis* as gathered at Niagara. The original, we are told by Gordon, *Pinctum*, ed. 2, 409, was raised by Ware, of Coventry.

Another *Wareana*, that of Booth's *Catalogue*, was probably a form of *Thuya* § *Biota orientalis*, and called also under the names *tatarica* and *sibirica*. This *Wareana* of Booth we do not meet with in our collections.

THUYA JAPONICA (MAXIMOWICZ).—This is the Japanese representative of the N.W. American *T.*

plicata (*gigantea*, Hort.), and if it did not come from such a distant region, it would, no doubt, be considered as specifically identical with it. It is the *Thuya*, or *Thuopsis* *Standishii* of gardens. We have only seen young plants in the nurseries, and herbarium specimens. It is quite likely that more mature specimens would show greater differences than are now apparent; nevertheless, even now, some differences are conspicuous. As compared with *plicata* (*gigantea*, Hort.), *japonica* has its branches of a yellowish colour, less flattened; in fact, they are convex, and remind one of whip-cord. The leaves are less glandular, not so flattened as in *gigantea*, Hort., oblong-acute, or some-

grouped. We may spare the reader the interminable synonyms and references to other forms and varieties.

1. **T. OCCIDENTALIS**, LINNÆUS
var. *plicata* = *T. plicata* of gardens
var. *Wareana*,
and very many more.
2. **T. Plicata**, D. DON, in Lambert, Pinus
= *T. gigantea*, Nuttall, and of gardens.
= *T. plicata*, James Donn (without description).
3. **T. JAPONICA**, MAXIMOWICZ
= *T. Standishii*, Hort.

Showing branchlets, foliage, cones, and seed.

what thickened at the apex, and with less tendency to acuminatio, often with a central ridge or mid-rib. The cones are very similar to those of *gigantea*, about 10 mill. long by 5 broad, generally shorter and thicker than those of *plicata* (*gigantea*, Hort.). When the eye becomes accustomed to the plant, there is, in fact, rarely any difficulty in identifying it, as, in addition to the marks above-mentioned, it has an indescribable but very perceptible difference in appearance or *facies*. Its branchlets turn colour and drop off in the autumn. We have had it for several years in cultivation, and have found it perfectly hardy even in the most severe winters.

This was one of Fortune's discoveries in Japan, and the credit of introducing it to cultivation is attributable to the late Mr. Standish. It has been called *Thuya* *Standishii*, *Thuopsis* *Standishii*, and *Thuya gigantea* var. *japonica*, but must not be confounded with the form of *T. orientalis*, called *japonica*.

The species and varieties mentioned may be thus

HOME CORRESPONDENCE.

POTATO PRICES.—Whatever may be the nature of the Potato trade elsewhere, it seems to be in low water about King-ton-on-Thames, as a recent report of the proceedings of the Rural Board shows that some 15 tons of Stourbridge (Glor) had been seeking for a customer, and had, so far, been unable to find one. Perhaps a little light was let in upon the sample offered when, in reply to a suggestion that the lot be offered to the Board of Guardians, it was said that the Guardians purchased only of the best. If, therefore, the stock was not good enough for paupers, it was doubtless not good enough for the general public. This much, however, may have been but a touch of local humour. The fact seems to remain, that old Potatoes are a glut in the market, and whilst we heard so much last autumn of the ravages of the disease, there seems to have been left of sound tubers more than enough to satisfy all the nation's needs. Kaisers' efforts of late have been so much directed to

the production of great cropping and disease-resisting varieties, that high table quality has been greatly ignored. Having got so many great producers, more attention might now be given to the production of meanness and better flavour, if it be possible to obtain these undoubted essentials to a good Potato, without materially undermining its constitution. It is certain that no present tendency to unprofitable prices in the Potato market will check planting or production. Immense breadths are being planted this season, and no doubt there will be to lift later an abundant crop. The blame of this result, if worthy of blame, must rest with the raisers of such wonderfully productive varieties. *A. D.*

BRAMLEY'S SEEDLING APPLE.—In your issue of the 10th inst., I notice your contributor, "C. H.,"

RICHARDIA ROSSII.—We note the remarks of your correspondent, "J. B. R.," in your issue for this week, but we think it is quite probable he is mistaken, and not Mr. Ross. We extract the following from a letter we have had from the latter gentleman:—"I believe this variety is new—in fact the superintendent of the Botanic Gardens declares the plant distinct from Elliottiana and Pentlandi, and a decided improvement. As I was the first to flower this variety, and the only holder of the stock, Mr. Chawin, of the Botanic, has named the variety *Richardia Rossii*." According to the above, Mr. Ross evidently is thoroughly conversant with *R. Elliottiana*, although "J. B. R." perhaps did not know it. However, we hope to put this matter straight within a few months, when the plants will be flowering, as we hold all the stock in Europe. *W. L. Lewis & Co.*

actually distinct, for so many that are in commerce are but selections of popular varieties, the range of variety in Carrots is much less, though for all ordinary purposes it is ample. Whilst April 9 is not early for sowing Carrot seed, it is early for Beet, but distance from home compelled me to make all sowings at once. If the latter fall, happily I have seed in reserve for a later sowing. One great subject of interest in relation to vegetable trials is noting the different effects on varieties by diverse soils. That can be done admirably in the county of Surrey, where we have soil variation in abundance. *A. D.*

SPIRÆAS?—At the spring flower show of the Royal Caledonian Horticultural Society, held recently, an interesting feature of the exhibition was a large group of handsome, well grown plants of so-called

FIG. 87.—*THUYA JAPONICA* (TANSHI). (SEE P. 258.)

asserts that Bramley's Seedling Apple is merely a "local" variety, and will only fruit well in a certain district, the location being left entirely to the reader's imagination. I think it only fair that I should be allowed to reply to this, as it seriously affects the character of the Apple. I can submit testimonials, voluntarily given to yourself or other independent authority, describing how freely it fruits in different parts of England, Scotland, Ireland, and Wales; and if further proof is required, it is only necessary to refer to the account of the last October show of fruit at the Crystal Palace, under the auspices of the Royal Horticultural Society, where, out of eight or nine exhibitors for the special prizes given by the Society for this Apple, the 1st went to Chippenham, the 2nd to Newbury, and the 3rd to Reigate. I will also submit to you and your correspondent, if he will kindly send his name and address, a few fruits each of Bramley's Seedling Apple and Lane's Prince Albert for comparison in cooking, when I am sure the verdict of a fair trial will be in favour of Bramley's Seedling. *H. Merryweather.*

BEEFROOTS.—The rather extensive trial of Beet-root conducted in the Royal Horticultural Society's gardens at Chiswick last year, whilst held under unfavourable conditions as regarded the weather, showed that whilst few foreign stocks were worthy of cultivation, we had some home-grown stocks or selections that were really of first-rate quality. But in most cases the excessive autumn rains led to the production of abnormal leaf and root growth, the Chiswick soil, though very porous and quickly drying in hot weather, is yet comparatively rich, with ample moisture, which creates free growth. Desirous of seeing how far the varieties that were good at Chiswick—Cheltenham Greentop, Dell's Crimson, Nutting's Dwarf Red, and Egyptian Turnip-rooted, with a few others of good reputation, would thrive on almost pure black sand, I have sown seeds at Englefield Green for trial purposes. I have also sown on the same plot seed of seven selected stocks of varieties of Carrots, for the soil has the reputation of turning out very handsome clean roots. But whilst we have many Beets, though really few that are

Spiræa. No. 44 in the prize schedule reads thus "Four *Spiræa*." No. 45, "Six do., in pots not exceeding six inches." What those who framed the schedule expected to obtain in competition, is not clear. All the three prizes, however, in No. 44 were awarded to different collections of *Astilbe japonica*, which, of course, is not a *Spiræa*; but so slowly does error die, that even yet it is so regarded by many gardeners. But that a desire exists among competitors, even at a flower show, to act fairly according to their lights, is a more hopeful sign of the future. In the next entry, No. 45, there seem to have been some qualms of conscience among the exhibitors that all was not right, for we now find exhibited several lots of the real "Simon pure" in *Spiræa astilboides*, and the judges awarded the prizes as follows.—1st, *Spiræa astilboides*; 2nd, (spurious) *Spiræa japonica*; 3rd, an intermediate form of the two former, called compacta multilobis. In the case of the plant called *Spiræa astilboides*, there is, unfortunately, no lack of botanical authority in support of the name. The

great *Index Kewensis*, for example, refers it to *Spiraea Arneus*. Notwithstanding all this, it is no more a *Spiraea* than the spurious *Spiraea japonica*. Any one who takes the trouble to examine a flower of this so-called *Spiraea astilboidea* will at once perceive that it belongs to Saxifragaceae, and not to Rosaceae, as does *Spiraea*, and that, in fact, it is an *Astilbe*. This has already been pointed out by M. Emile Lemoine, of Nancy, in an article which appeared in the *Gardener's Chronicle*, September 25, 1895, p. 378. M. Lemoine advocates the rejection of the name *Spiraea* as applied to this plant, and is inclined to adopt the rather incongruous name of *Astilbe astilboidea*. In a foot-note, however, he suggests that the name *Astilbe arneoides* would be more in accordance with "facts and logic." This latter would be a most appropriate name; but why not simply transpose the name from *Spiraea astilboidea* into *Astilbe spiraeoides*, and thus make it also more in accordance with facts and logic? One can hardly imagine that so eminent an authority on the genus *Spiraea* as M. Lemoine would make the mistake of naming an *Astilbe* for a *Spiraea* of the *Arneus* group, and the true *Spiraea astilboidea* may yet be brought to light. Be this as it may, the fact remains, that the plant in ordinary cultivation under the name of *Spiraea astilboidea* is a Saxifragaceous plant, similar to *Astilbe*, and not Rosaceous, like, like *Spiraea*. R. Lousley.

THE RENASCENCE OF THE HOLLYHOCK.—A good many signs alight in our gardens and at our great autumn shows tell us that this has not only begun, but is in more or less vigorous progress. A feeling of new hope and heart is abroad that the fungus pest has done its worst, and that the salvation of the Hollyhock may be found in cooler culture, invigorated constitution, and perhaps thicker skins or epidermis alike, of the leaves and stems of Hollyhocks. But be all this as it may, not a little towards a perfect renascence of the Hollyhock from weakness and disease has already been accomplished. This was abundantly evident from the perfectly clear and exceptionally vigorous plants, known and outstanding by Mr. Forbes of Hawick, to illustrate a lecture I gave at the Royal Botanic Gardens on the Hollyhock on the 2nd of this month. The plants afforded admirable illustrations of the grafting of choicename double Hollyhocks by various methods. I send you a sample of stems, cuttings, and of the size and vigour of the leaf and leaf-stalk, which speak for themselves as to their vigour and cleanliness. Mr. Forbes lost one of the finest collections in Britain in 1875; but instead of sitting down and bringing his hands in despair, he began immediately making a new collection, and surrounded it with such guarantees and sanitary measures as seems to have assured its safety. But our main interest in the present, and our hope for the future, lies in the fact that his fine collection is warranted clean, and that the most stringent rules are adopted to keep out infected stock. D. T. F.

EARLY-FLOWERING RHODODENDRONS IN CORNWALL.—The weather has been most favourable for early-flowering varieties. We had good trusses of *R. Nolleannum* open in November, and have rarely been without blooms since. There is nothing I think more beautiful amongst hard-flowering plants than one of these Rhododendrons in flower on a sunny morning in February. I enclose you a photo of a plant taken on February 24 last, the flowers of which are just beginning to fade—I think the variety is *R. Broughtonianum*, but I am not certain, as the plant shows no sign of having been grafted—it may be a singleling. I am forwarding a box of blooms, amongst them some of a new collection, and surrounded it with such guarantees and sanitary measures as seems to have assured its safety. But our main interest in the present, and our hope for the future, lies in the fact that his fine collection is warranted clean, and that the most stringent rules are adopted to keep out infected stock. D. T. F.

VOLES AND MICE.—Mr. J. Simpson of Wortley, writing in your issue of April 3 last, classifies these rodents as distinct, by their modes of doing mischief. Mr. Simpson's article was in reply to ours in a preceding issue, in which we stated the damage they led to a large break of Scots Fir in our nursery here. We were in hopes that some eminent authority would have had something to say in last week's issue, and that the subject of voles or mice; or, more correctly, field-mice. It is of small importance whether it is vole or field-mouse, since it is a fact well-known to observers that both of these nibbling vermin do damage to young trees; and in all severe attacks, both the long-tailed and the short-tailed field-mice have been present, the short-tailed variety, or so-called species, predominating. Close observers have seen both sitting on the young trees nibbling at the buds, and have killed them in the act, the short tailed

being always more numerous than the long-tailed, or common field-mouse. The device of digging pits to trap voles and field-mice is an ancient, and generally successful one. The success of the method was amply proved in this country so far back as the year 1514, when over 30,000 of them were so trapped in the Dean forest, and about the same time large numbers were caught by the same method of pitfalls in the New Forest. In these instances it is recorded that in both forests the two sorts of mice were observed, but the short-tailed were by far the more numerous, which coincides exactly with our own annoying experience this spring. In any case, both sorts get into young trees and nibble at the buds, and both are trapped by the same means—pits, or mouse-traps of various kinds. Stiff-growing, well-featured Scots Fir, some 15 to 18 inches high, would not be a very difficult task for any rodent of the mice tribe to climb, more especially when growing in nursery lines, and we are of the opinion that the short-tailed, being the more numerous, caused more damage amongst the buds than the long-tailed. *Louisa Mather, Kilsnoe, Ireland.*

—Oliver Goldsmith, in his *History of the Earth and Animated Nature*, says that soon after the formation of the Forest of Dean and the New Forest, much injury was done to the young trees, Chestnuts and Oaks, by mice, trees of five years old having had many of their roots gnawed through just under the surface of the ground, while Hollies 5 and 6 feet high were attacked, and severely barked; the mice, in some instances crawled up the trees, gnawed and ate the bark off the upper branches. In fact, so sudden and rapid was the increase of the depredators that it was feared the whole of the plantation would be destroyed. Various methods were adopted to rid them, in the way of traps, &c.; but that which proved the most successful was to dig holes (much wider at the bottom than the top) 18 inches deep, 2 feet one way, and 1 foot the other. In these holes some 30 or 40 mice were caught, and it was thought probable that the total number destroyed by hawks, owls, stoats, &c., amounted to 200,000. *H. Markham.*

ASPARAGUS PLUMOSUS.—Mr. Reynolds has planted the back wall of the early vinery at Gunnersbury with this valuable plant, placing the plants in fairly roomy boxes, the shoots cover the wire wall at the back, as soon as forcing begins. The Asparagus makes a free growth, and supplies an abundance of material for cutting, and towards the surface of the close, and the plants appear to take a spell of rest. The vinery is thrown open after a crop is gathered, and this change of temperature affects the Asparagus similarly to the putting on of heat, for a very free growth is again put on, as if the plant was desirous of doing its utmost service to the cultivator. *R. D.*

TRANSPLANTING BRACKEN.—The transplanting of the common Bracken Fern seems a simple operation, though it is often asked to explain the cause of failure in establishing the Fern in a new spot. To be successful one must take up sods not less than 6 inches in depth, and a foot or so square, choosing the sods where the Bracken is thickest. The sods should be laid on a hard bottom, and soil rammed hard round each sod, as the black rhizomes of the Fern seem to prefer a hard medium to root in. If the transplanting is done in this way, rather than by lifting small bits of the rhizomes, success will follow. Now is a good time for transplanting, or any time before the fronds are a few inches high. Being so common in some parts, and so rare in others, I think it worth knowing how to transplant such a beautiful wild plant from one district to another. *H. Goldring.*

SOCIETIES.

LINNEAN SOCIETY OF LONDON.

APRIL 1. DR. A. G. STEVER, F.R.S., President, in the chair.

Mr. W. T. THURGOOD, Esq., exhibited—1. A series of drawings (on the screen) to illustrate the "Cultural evolution of *Cyclamen latifolium*, Sibth." The species is a native of Greece and the Levant, and is believed to have been first introduced into European cultivation in 1731. In 1768 Miller described a form modified by cultivation under the name of *Cyclamen persicum*. This name was erroneous, as, according to Boissier, neither the wild nor the garden form occurs in Persia. The latter persisted in cultivation for about 150 years, and about 1850 became the starting point of the modern races which were illustrated. *Cyclamen latifolium* has never been hybridized, and it was shown that the

striking forms now in cultivation were the result of the patient accumulation of gradual variations. Drawings of the remarkable forms "Pavilio," obtained by de Langhe-Vervaeke, and of "The Bush Hill Pioneer," by Messrs. Hugh Low & Co., were shown. It was pointed out that the tendency of the species under cultivation was to lose its distinct generic character, and to approach in more generalized type. The reflexion of the corolla-segments was often lost as in *Lysimachis*, the segments were sometimes multiplied as in *Trientalis*, and the margins were fringed as in *Soldanella* and cultivated forms of *Primula sinensis*. "The Bush Hill Pioneer" possessed, in the creasing of the petals, a remarkable character which was parallel in many primitive forms that occurring in a wild state. (We believe a similar condition occurs in the nearly allied order *Myrsinaceae* E. B. P.) A series of plants was exhibited to illustrate the origin of the garden "Cineraria." It was generally agreed that this had sprung from one or more species native of the Canaries. An extreme cultivated form was shown and compared with *Senecio crenatus*, which all internal evidence indicated as the sole original stock. S. Heritieri, another reputed parent, was exhibited. But it was pointed out that this was a slightly hybrid, and stems markedly zigzag between the internodes, while the leaves are dark, glaucous with a dense white tomentum. These characters it transmits more or less to its hybrid offspring. In illustration of this point Mr. Poir's hybrid (*S. super-Heritieri* × *crenatus*) was exhibited (a similar one has occurred at Edinburgh); also the standard form of *S. crenatus* which is the parent of the crosses very freely with the garden *Cineraria*, and the latter never exhibits any trace of the characters of *S. Heritieri*, it was concluded that that species had no part in its origin, and that, as in the case of the *Cyclamen*, the striking development of *S. crenatus* in cultivation was due to the continued accumulation of gradual variations.

Mr. A. W. BEXSER exhibited a series of drawings by Mr. E. B. Green of root-bears of plants with various parasitic growths, and showed preparations of several under the microscope.

ROYAL HORTICULTURAL.

APRIL 13. A magnificent display was made at the usual meeting of the Committee held on Tues. Ev. last in the Drill Hall, James Street, Westminster. The capacity of the hall is always tested at the meeting in April, when, in addition to the usual class of exhibits, there is the annual show of the National Acclimatization and Primula Society. We have seldom or never, however, seen the hall so crowded with plants and flowers as on this occasion; and Mr. W. Light, the Superintendent, from Chislehurst, and Mr. J. H. G. in grouping exhibitors even a portion of the space they required. Several of the centre tables were occupied with the *Arniculas* and *Primulas*. Some of these might have been accumulated in one of the galleries.

Under the wall on the left side of the hall were staged a number of groups of miscellaneous plants which together made a considerable bank. The collections of *Roses* were numerous, including plants in pots, and cut flowers. An increased number of *Orchids* was staged, and magnificent displays of *Narcissus* bloom came from the trade. A collection of hybrid *Narcissus* from the Rev. G. H. ENGLEBERT, included several choice novelties. There was again a number of excellent *Hippocratus* staged, and the largest collection by far was from an amateur. In the afternoon a Lecture was delivered by Mr. J. W. WELLS on Artificial Manures.

Floral Committee.

Present: W. Marshall, Esq., in the chair, and Messrs. H. B. May, H. Herbst, J. Fraser, J. H. Pitt, E. Owen, J. Jennings, J. F. M. Leod, R. E. Lowe, C. J. Saller, C. Jefferson, J. D. Pugh, C. E. Shea, E. Massey, G. Gordon, C. E. Purdon, J. W. Barr, H. Cutbush, E. Beckett, J. Ling, H. J. Jones, J. Walker, W. Dorr, R. M. Hogg, J. Fraser, J. Hudson, T. W. Smiles, G. Paol, C. Elck, H. Turner, and R. Don.

Messrs. CUTLER & SONS, Highgate Nurseries, London, N., had a capital exhibition of miscellaneous plants, including similar species to those shown from the same establishment on the last occasion (Brouse Flora Medal).

A very bright group of plants from Messrs. JOHN LIND & SONS, Forest Hill Nurseries, London, N., included some well-flowered plants of *Azalea mollis*, *Ericas*, Turner's *Crimson Rambler*, *Roses*, *Colla Portlandia*, *Hydrangeas*, *Cyclamens*, several good *Orchids*, &c. Silver Flora Medal.

Mr. H. B. MAY, Jysons Lane Nursery, Upper Edmonton, N., had a group of plants, including many choice Ferns, *Palms*, *Dracaenas* and *Aralias*, a *Paragus* Sprengeri, several foliage *Begonias*, &c. (Silver Rankin Medal).

A magnificent group of spring-flowering plants was arranged upon the floor near the door by Mr. J. F. McLeod, gr. to J. P. MORGAN, Esq., Spence Cottage, Bechampton, Azaleas, *Boronicas*, *Lilacs*, *Hippocratus*, *Ericas*, *Lilium Harrisii*, and other forced plants were intermixed with *Crotons* and *Dracaenas* of good colour. *Calceolarias*, *Palms*, and other choice foliage plants. One dozen plants of *Azalea Deutsche Perle*, from the same exhibitor, were exceedingly well-flowered (Silver-gilt Flora Medal).

A group of plants of double-flowered *Cinerarias*, representing a number of shades in colour, from purple and rose to almost pure white, was contributed by Messrs. Kewey &

Sizes, Langport Nurseries, Somerset. It was a distinct exhibit of considerable attraction (Vote of Thanks).

Messrs. PATE & SOSS, The Old Nurseries, Chesham, made a display with roses in pots. Such varieties as the following were well-flowered and capital plants: Captain Hayward, Céline Forestier, Gustave Figeaux, Mrs. S. G. Crawford, Madane Hoste, Madane de St. Joseph, Elise Fugère, Beauté Indienne, Georges Lemoine (a pretty button-hole rose), and others. In front of and between the plants, were several interesting species of lady plants. We should have mentioned the new H.P. Rose, Lawrence Allen, a new, fresh-coloured, with wide petals, and apparently of strong growth (Silver Flora Medal).

Mr. GEO. MOORE, The Rose Nurseries, Canterbury, had a few Roses in pots, and a magnificent display of cut blooms, some of which were in sprays of upwards of one foot in length, and having an abundance of healthy, vigorous foliage. That excellent variety, "Weiss" was shown largely, and many other well-known varieties (Silver Flora Medal).

(Roses were also shown by Mr. J. W. WALKER, Thame Nurseries, Oxon, who had a rare lot of blooms of Maréchal Niel, and Niphetos (Silver Banksian Medal).

Mr. W. RUMBY, Jorning's Nurseries, Waltham Cross, made a pretty display immediately facing the entrance to the show. The new variety, Mrs. Hamsay, was well shown; as cut blooms, and in plants. Niphetos and others were good (Silver Banksian Medal).

An exhibit of the beautiful Rose, Fortune's Yellow, in a number of sprays, from Mr. Fyfe, gr. to Lord Warriston, Lockinge Park, Wantage, was most attractive (Silver Banksian Medal).

A Bronze Banksian Medal was deservedly awarded to E. MAWLEY, Esq., Berkhamsstead, for an exhibit of Roses.

Mr. S. MORTIMER, Rowledge Nurseries, Farnham, exhibited two seedling varieties of ornamental Chrysanthemum, named Minnie and Margenta reigning. The other, Eastern Queen, was very robust, of somewhat coarse habit, and with promiscuously variegated foliage. A number of plants of each variety were shown.

A large group of Hippeastrums was sent by Captain Holt, Westcott, Tetbury, Gloucestershire (gr. A. Chapman). Many of the seedling varieties were of very commendable quality, while others were of less merit. All had been well cultivated. The colours in a great proportion of them were uncommonly bright and distinct. Duke of York, and one crimson self, with two flowers of unusual substance, were recommended an Award of Merit; as also the varieties The Czar and Chimborazo, both dark self-coloured flowers of much merit (Silver Flora Medal).

In a group of excellent Hippeastrums shown by Messrs. J. S. VERRILL & SONS, Royal Exotic Nursery, Chelsea, the following varieties were recommended Awards of Merit: Topaz, a flower of good form, bright in colour and freely variegated with white; Brenda, a large scarlet crimson flower, with green base; Ignacita, a plant with four flowers upon a scape, white veined in the upper segments, principally with red; and Thomson, a large flower of scarlet with green base, and expanding considerably widely.

A variegated Potato was shown by Mr. E. BECKETT, Aldenhara House Gardens, Epsom. A large basket of the plants was shown, each being very freely variegated with white (Award of Merit).

Mr. THOMAS S. WARE, Hale Farm Nurseries, Tottenham, in conjunction with a large exhibit of hybrid blooms, showed a few lady plants, including *Anemone fulgens*, *gentiana analis*, *Anemone apennina* alba, and several *Fritillaria*, &c.

Messrs. H. WALLACE & CO., Kimbich Garden, Colchester, showed several very pretty Erythroniums in flower, including E. revolution, which was awarded a First class Certificate. The flowers of the spikes were about twelve inches high, the flowers about two-and-a-half inches across, rose coloured, but varying considerably—a handsome species of robust growth, foliage broad and marbled. A smaller plant was shown as E. revolution, var. Bolanderi, with white flowers, excepting for a yellow band at the base. *Fritillaria pudica* and others were also shown.

Messrs. H. CANNELL & SONS, Swanley, Kent, exhibited a large plant of *Fuchsia* "Aldington," a hybrid between *fulgens* and *F. cordifolia splendens*. The flowers are rose-coloured, tube about one inch long. The plants are mostly free-flowering (Award of Merit). See p. 257.

Messrs. CANNELL & SONS also showed a spray of *Tropaeolum Flore* with bright yellow flowers, each petal marked with orange vermilion, and deeply fringed at the margin (Award of Merit).

Messrs. J. LAMBE & SONS, Forest Hill Nurseries, London, S.E., obtained an award of merit with *Ornithogalum luteum*, a well-known species with white flowers of considerable size.

Messrs. BARK & SONS obtained an Award of Merit for Muscard cornum, a showy, strong-growing species with large, bright blue flowers, produced about 6 inches high.

A Silver Banksian Medal was awarded the GUILDFORD HARDY PLANT Co. for a fine display of *how Atrivivus*.

Narcissus Committee.

Present: REYS, S. E. Bourne and G. H. Engelhardt, Miss Willmott, Messrs. C. R. Scarce-Birkins, Jas. Walker, A. Kingmill, J. de Graaf, and J. T. Bennett POC.

The copious rains of March and April have brought the Narcissus to their culmination in the earlier part of the present month. The Trumpet Daffodils were at their best in the South of England a fortnight ago, but the north season is later kinds—the "medio-cornuti" and "peri-cornuti"—later kinds will fall far behind on this occasion, and characterised by the purity of colour and freshness given by a mild and moist spring.

The lover of Daffodils always looks to Messrs. BARK & SONS for an ample trade exhibit, and certainly there was no disappointment at the last meeting in either quantity or quality. Almost every variety in commerce was represented, and the flowers were exceptionally good in colour, especially those of the Barbadoes section (Silver-gilt Flora Medal).

The latter collection was the hand in point of merit by the very large bank of all varieties staged by Mr. T. S. WARR, Hale Farm Nurseries, Tottenham, who also gained a Silver-gilt Flora Medal. We would, however, suggest that the flowers were crowded together so tightly in bunches as to lose much of their effectiveness, a criticism which may also be made of the "striped Daffodils" for size, but which would have been seen to much greater advantage if only half the number of blossoms had been put into each bunch (Silver-gilt Banksian Medal).

In the amateur competition for Messrs. BARK'S Silver Cup, the only entry was that of J. E. BARNES-POL, Esq., whose excellent flower well deserved the award. The red-crowned posternum was unusually bright.

The Rev. G. H. ENGLEHART had the largest exhibit of his own seedlings that he has yet shown. Appended to it were interesting notes upon the parentage of the several groups, which rendered his stand an object-lesson in hybridisation. The centre was occupied by numerous examples of "recombined" colour, conspicuous being *Br. Deinde*, a solid, broad-petalled flower of the Nelson class, with a large cup of fiery orange-scarlet (award for the premier seedling); Beacon, a more stately flower, with crown wholly of intense red (First class Certificate). Many hybrids of *N. triandrus* were in evidence, of which Snowdrop Albicans, a triangular obtusely pointed flower, was well deserved the award. Others were also shown, noteworthy for increased size and deeply-coloured eyes. An Award of Merit was given to *N. incomparabilis Beauty*, from Messrs. BARK & SONS.

Orchid Committee.

Present: Harry J. Veitch, Esq., in the chair; and Messrs. Jas. O'Brien (Houl. Sec.), W. B. Crawshaw, H. M. Pollett, C. J. Lucas, H. Ballantine, W. H. Young, W. H. White, W. H. Protheroe, A. H. Snee, E. Hill, F. J. Thorne, W. Cobb, F. Mason, T. D. Hayward, S. Courtauld, J. Douglas, and H. J. Chapman.

The large number of groups of orchids greatly taxed the resources of the hall, and extra tables had to be arranged to meet the demand for space.

Messrs. JAS. VERRILL & SONS, Ltd., Royal Exotic Nursery, Kings Road, Chelsea, were awarded a Silver Flora Medal for a very fine group of rare and excellently grown *Orchids*, very interesting feature in which was a fine cut flower of *Phlegmarion*, a very fine specimen of *Phlegmarion*, one of the sprays having five fine blooms; with it were the pretty little white and violet E. Andresii, from which Messrs. VERRILL have evolved the beautiful and floriferous E. Andresii-Wallisi and E. elegantissima, both of which were represented by several varieties. Also shown for the first time was *Lobelia* (*Cathaya*) *Digbyano-Triandri*, which secured a First class Certificate.

In colour in the fringing of the lip it is similar to the fine *L. C.*—*Digbyano-Mossii*, illustrated in the *Gardener's Chronicle*, May 25, 1893, p. 657. Messrs. VERRILL also received a First class Certificate for *Phlegmarion*. Perennially expert were Messrs. Charles Carter & Co., Antioch House, 53, a very nice lot of *Zygopetalum*, with bright white-lip and purplish-brown sepals and petals, with a few slight greenish bars. Also very noteworthy in the group were *Cattleya Schobereana*, a charming peach blossom coloured flower, with orange glow in the tube. Two good examples of the richly coloured *Phlegmarion*—*Lobelia* (*Cathaya*) *vesania* (L. S. Thoma × C. Triandri), with light yellow sepals and rose purple lip; *Clypeis* × *Chelsoni*, *D. indubium* × *Wardiana japonicum*, *D. × chrysochrysa*, *D. × cybele nobilis*, *D. × allepica*, *D. × aspera*, a fine pan of *Masdevallia Veitchii*, *A. Anselmi*, *Cymbidium*, *Chamae Looianum*, *Chamae Textorii*, *Oncidium Sarowae*, &c.

Baron SIR H. SCHOMBER, The Dell, Egham (gr. Mr. A. Balantine), showed *Odontoglossum Wilckeanum* ("Queen Empress"), about which there was no two opinions as to its being the finest example of its class, and well deserving the First class Certificate awarded. The flowers were large and broad, bright yellow in the margin and the centre, and a soft, translucent, rich chestnut brown; petals yellow, heavily spotted with brown. Baron SCHOMBER also sent a fine inflorescence of his handsome hybrid *Odontoglossum*—*Dellense*.

SIR THOMAS LAWRENCE, Bart., Bedford, Dorking (gr. Mr. W. H. White), staged a good group, remarkable for the excellent examples of culture shown in the plants, three of which, viz., *Cymbidium Devoniense*, with several fine spikes; a large specimen of *Millettia cruenta*, and a finely flowered *Maxillaria grandiflora*, were awarded Cultural Commendation; and a number of spikes cut from a large specimen of *Orchis* (data secured for that plant a Botany &

Certificate). In the group also were a pretty plant of *Leptotes bicolor*, *Cypripedium glanduliferum*, the elegant *Dendrobium* "The Pearl," *Devoniense* album, *D. signatum*, *D. Brucerianum*, *Phaius Martii*, *Epipedium Emireisii*, *Masdevallia leontoglossa*, *M. × Geleniuma*, *M. × Shurt* (trayana), *Chamaeris* variety, and *Maxillaria luteoalba* (Botanical Certificate). &c. The group secured a Silver Banksian Medal.

Major JOCKEY, Sunningdale Park, Sunningdale (gr. Mr. F. Thorne), staged a group composed principally of grand plants of the large white *Dactyloctenium* (*Epilobium*) *bicoloratum*, which most growers deem almost impossible to grow. Nothing could be finer, more vigorous, and floriferous than these, and the Silver Flora Medal awarded was for the culture of the plants in this group. Also with the *Dactyloctenium* were a grand specimen of *Dendrobium thyrsiflorum*, *Epilobium atripurpureum* album, *Odontoglossum Hallii*, &c.

J. BRADSHAW, Esq., The Grange, Southgate (gr. Mr. Willmott), staged a fine group, in the back of which were many of *Epilobium Looianum*, and in the front a fine lot of heart *Dendrobium Janestianum*. In the body of the group were good *Odontoglossum Pescadorei*, *O. crispum*, *O. Hallii*, *O. Andersonianum*, *Lycaste*, &c. (Silver Banksian Medal).

Messrs. F. SUTTON & CO., St. Albans, were awarded a Silver Banksian Medal for a very interesting group, a fine lot in which was a noble plant of *Zygopetalum Bartii*, with ten grand, wax-like, brown, yellow, and white flowers. Other good things were *Dendrobium Harveyanum*, *Cypripedium Minnie Ames* (concolor × *Curtisii*), *Cymbidium javanicum*, *Stenoglossis floricincta*, *Phaius Owenianus*, *Phalaenopsis Boscii*, *P. rosea lucida*, a fine lot of *Lycaste*—*Stenoglossis*, and *Miltonia* varieties.

Messrs. H. W. LOW & CO., Clifton, staged a good group, composed of *Dendrobium thyrsiflorum*, *D. × graciosissimum*, *Miltonia Bredii*, *Oncidium Kraneri*, *Odontoglossum Hallii*, *O. triumphans*, *O. crispum*, *O. luteo-purpureum*, *O. Andersonianum*, &c. (Silver Banksian Medal).

D. B. CRAWSHAW, Esq., Rosefield, Sevenoaks (gr. Mr. Carter) showed a group of excellently grown *Orchids*, including several distinct varieties of *Odontoglossum Andersonianum* and others of that class; a noble form of *O. triumphans*; a very large and richly-coloured *O. luteo-purpureum*, which has been grown by Mr. Crawshaw from a small plant, and has been in his collection sixteen years (Silver Banksian Medal).

MARYS CAMBER, Rayham Abbey, Lamberhurst (gr. Mr. A. Methuen), was awarded a Silver Banksian Medal for a group of *Dendrobium Wardianum*, *D. Devoniense*, *D. nobilis*, *Cypripedium*, &c.

J. T. BENNETT POOL, Esq., Homewood, Chesham, received a Cultural Commendation for a stand of splendidly grown *Cattleya citrina*.

A stand of good *Cattleya citrina*, set up with cut blooms of *Cattleya Schobereana* and *Miltonia* (gr. Mr. F. Thorne) was also set up by W. C. WALKER, Esq., Ferry Lodge, Winchester Hill (gr. Mr. Geo. Gifford) (Vote of Thanks).

E. J. JOHNSON, Esq., Romlam Hill, Bury St. Edmunds (gr. Mr. H. Henley), received a Cultural Commendation for a finely flowered *Cattleya Schobereana*.

C. J. LUCAS, Esq., Warrimoor Court, Romham (gr. Mr. Deane), exhibited a number of cut spikes of splendid varieties of *Odontoglossum Andersonianum*, &c.

Captain J. H. WOODHEAD, Tetbury (gr. Mr. Chapman), showed *Lycaste Skinneri* Westcott variety, a large flower; the chief peculiarity was the white lip with rose-coloured margin.

FRED HARRIS, Esq., Tyntesheld, Ashton on Mersey (gr. Mr. Stafford), showed another of his good forms of *Dendrobium* × *Cybe*.

SIR WYKE DE SASS, Esq., Danhurst, Epsom, Mr. E. Short, was given an Award of Merit for *Odontoglossum Andersonianum*, Danhurst var. a very large and fine variety.

E. W. MARBLE, Esq., Lake House, Byfleet (gr. Mr. Bradley), was awarded a Silver Banksian Medal for an immense specimen of *Aurelia africana*, which had been grown since 1892, and now bore nine spikes with, in the aggregate, six flowers. The fine old plant was also given a Botanical Certificate.

C. L. S. JOHNSON, Esq., Elford House, Godalming (gr. Mr. T. W. Bond), again showed the pretty *orchid* *Cattleya*, Sir Wm. Ingram, which received an Award of Merit last year; and *Cattleya* × *Wm Murray*.

J. WILSON PORTER, Esq., Singapore, Croydon, received an Award of Merit for *Odontoglossum Pescadorei*, *Shachuan yan*, one of the largest and best types, with perfectly formed, slightly rose-tinted flowers.

Messrs. E. S. WRIGHT & SONS, Victoria and Paradise Nurseries, Upper Holloway, staged an effective group, composed of a large variety of *Odontoglossum*, chiefly *lybica*, *Ada* *antiarctica*, various *Dendrobium*, *Cattleya Mendii*, *C. Curtina*, *Epilobium Pilsbottii*, several good *Cymbidium Devoniense*, *Chamae Looianum* (*C. luteoalba*), *C. cruenta*, *Phalaenopsis*, *Chamae Looianum*, *Chamae Textorii*, *Phalaenopsis*, *Phalaenopsis*, *Phalaenopsis*, &c.

Franz von BRANDER, Boshach, Zuzich, sent *Epilobium luteum* and *Odontoglossum luteoalba* (var. *luteum*).

C. J. CROFTON, Esq., Suffolk Park, Liverpool (gr. Mr. Baskley), showed good varieties of *Dendrobium Wardianum* and *Odontoglossum crispum* "Gloebilli," a large and finely formed flower.

Fruit Committee.

Present: T. Crowley, Esq., in the Chair, and Messrs. T. F. Rivers, G. P. Miles, J. Cheal, W. J. Simpson, W. Pope, J. Wright, A. Dean, J. A. Loring, J. Willard, W. Furr, W. Tades, C. Herrin, J. Smith, G. Reynolds, W. H. Davers, R. File, F. Q. Lane.

A collection of vegetables, including very good produce for the season, came to EARL FRYER, Syon House, Brentford (gr., Mr. G. Wythes). We may specify excellent Asparagus cut from forced beds in the open, ALLEN'S Favourite Cucumber, a nice-looking medium-sized fruit, ribbed and slightly spined; New Potatoes Sharp's Victor, Mushrooms, Vetch's 5th and 6th Crop Cabbages, the Kale and Loeks, Syon House prolific Tomatoes, Potato Assembled, Early Scarlet Horn Carrots, Cucumber Seedling, Sutton's Early Favourite Cabbage, a very early hearting variety; small Chion, and other salading, as well as all the various hardy vegetables in season. In all, fifty dishes of vegetables and nine punnets of *La Croix* variety Strawberries (Silver-gilt Knighted Medal).

Another and much smaller collection of vegetables and fruits came from Mrs. WINGFIELD, Amphill House, Amphill (gr., Mr. Empson). Very good were eleven heads of Carter's Mammoth Spring Cauliflower, Carter's Early Cabbage, St. Oystin and Early York Peas. The Seakale shown was well blanched, but drawn from too much heat having been employed. The fruiting plants of Royal Sovereign Strawberry, with from eight to twelve ripe fruits were very well done, showing well the capabilities of the variety. A large dish of the same was shown. A few dishes of Apples were included, the best-looking being Gloria Mundi, Wellington, and Tyler's Kernel. The table was backed by a row (eight) of plants in pot of Early Moon Pea (Award of a Silver Knighted Medal).

Mr. DRYER, gr. to the DUKE OF RUTLAND, Belvoir Castle, exhibited, for the season, a rather large number (56) of dishes of distinct Apples, many of them being fresh and plump-looking. Such were Pennine's Charm, Annie Elizabeth, King of Pippins, Cluster Golden Pippin, Baron Ward, Norhampton Wonder, Caldwell, Rosemary Russett, Jenkinson's Seedling, Hollow Crown Pippin (Silver Banket Medal).

A PEARS, Esq., Spring Grove, Isleworth (gr., Mr. F. Farr), showed new Hardy Fruiting Apples, and samples of Lady Downes Seedling of 1896, the latter having that desirable bloom on the berries one is accustomed to see at the end of the autumn. He also showed a basket of Royal Sovereign Strawberries of size fair and excellent colour, some small Mushrooms, Beans, &c.

In the Apple competition the 1st prize fell to Mr. C. ROSE, gr., Well-ford Park, Newbury, for his plate of Lord Bingley; and the 2nd to Mr. C. HERBERT, gr., Drogheda, Maidenhead, for a plate of Sturmer Pippin. No Pear show met with the approval of the Committee, Mr. R. C. HARRIS, of Jersey, showing seven very fine specimens of Belle de Jersey, or rightly Uvedale's St. Germain's.

NATIONAL AUBRICULA AND PRIMULA.

APRIL 15.—The exhibition of the National Auricular Society in the Drill Hall was at least a fortnight too early to have the flowers at their best. Many of the varieties staged showed signs of pressure on the part of the grower to get them into bloom at all. When the flowering period is hastened by the application of heat and other means, the flower is apt to resent the interference by coming coarse, and coarseness was the prevailing feature of the show Auriculars. They are much longer in expanding their pipes than the alpine types, and they are seen in the best condition when they can come on slowly into flower in their own way and time. But when the date of the show is too early, even in an early season, much less than in the retarding one we are now passing through, some assistance is necessary if the plants are to be had in flower by a given date. Even the alpine varieties appeared to be less refined than usual, as if they also had been pushed on into bloom; and some plants had only just got into flower, and it was with something like regret that notice could be taken of plants receiving prizes having two expanded pipes only. This is a departure from the old unwritten law of the old florist's procedure that class flowers should have five pipes, and those as single plants should have three pipes.

Some *Auriculars*.—There were four collections of twelve varieties, and Mr CHARLES PHILLIPS, Bracknell, Berks, a grower who has recently passed from the amateur to the dealer stage, was placed 1st, and in this class one may always expect to find the best plants in the show; he had of green edges, Mr. HENWOOD's 2nd, a fine new variety, Mr. DOUGLAS, a flower of the first quality. Mrs. BURNETT, redder in colour, but flat and smooth; and Heroine, somewhat out of character. Mr. A. J. SANDERS, gr. to Viscountess CHEWTON, Colham, Surrey, was 2nd, having, of green edges, Rev. F. D. HORNER, Prince of Greenes, and Abbé LISZT, white edges, Mr. HEADLEY, Hatched, and George RUISS, white edges, Mr. DODWELL, John Simons, and Acme; selfs, Heroine, and Mrs. POTTS. P. J. WORSLEY, Esq., Clifton, Bristol, was 2nd, and J. T. BENNETT F.-E., Esq., Ashley Place, 3rd.

There were four exhibitors of six varieties, Mr. C. PHILLIPS being again 1st, with green edges, Mrs. HENWOOD, and the Rev. F. D. HORNER; grey edge, George RUISS, and seedling white edge, in second place, Mr. J. HILL, Mr. PHILLIPS, and Mrs. BURNETT. Mr. A. J. SANDERS was again 2nd, having of green edges, the Rev. F. D. HORNER and Abbé LISZT; grey edge, George Lightbody; white edges, Acme and Mrs. DODWELL; and Viscountess CHEWTON, a bright violet self, in the way of Mr. POTTS. J. T. BENNETT F.-E. was 3rd, and P. WORSLEY, 4th.

With four varieties, those competing in the two foregoing classes being defeated from the next two, W. SMITH, Esq., Bishop's Stortford, was 1st, with the Rev. F. D. HORNER, Rachel, Acme, and Heroine, one of each class; Mr. A. R. BROWN, Birmingham, was 2nd having the Rev. F. D. HORNER, Heather Bell, white edge; and C. J. FERRY and HASTING, selfs. Mr. G. GILBERT, gr. to the Duke of R. FLOREN, Harrow, was 3rd, his two best flowers, green edge General Nichl, and Acme, white edge. Mr. A. R. BROWN had the best year, staging grey George Lightbody, and white Heather Bell. W. SMITH, Esq., was 2nd, with Abbé LISZT and Rachel; Mr. GILBERT being 3rd.

The best specimen green edges was Rev. F. D. HORNER, which was awarded the 1st prize, the awards being made in the order of the names of the exhibitors, Messrs. A. J. SANDERS, C. PHILLIPS, and the GUILDFORD HARDY PLANT NURSERY Co. Abbé LISZT and James Hamford came next in the order of merit. That fine variety George Lightbody came 2nd, and the 1st three prizes in the class for grey edges, Messrs. J. DOUGLAS, C. PHILLIPS, and A. J. SANDERS, being the exhibitors. Marmion, George RUISS, and GREY FRIAR were also shown. That fine white edge, Acme, took the three best prizes in the class for a white edge, Messrs. DOUGLAS, PHILLIPS, and J. D. BENNETT F.-E. being the exhibitors. George RUISS and Rachel were placed lower by the judges. Mrs. POTTS took the three last prizes in the Self class, Messrs. DOUGLAS, FISK, and the GUILDFORD NURSERY Co. being the exhibitors. Mrs. PHILLIPS, not so finely shown here as in Class A, was 4th, following Heroine.

The GUILDFORD NURSERY Co. were 1st with fifty Auriculars, which were not so common as the other classes, they were able to put their best into this class, and win easily. They had of green edges, the Rev. F. D. HORNER, Abbé LISZT, and John Garrett Adams; grey edges, George Lightbody, Colonel Champaigne, Dr. HORNER, Ringleader, and George RUISS; white edges, Acme, The Fairy, Sailing Beauty, and Heather Bell; selfs, Heroine, Lord of London, Buttercup, Mrs. POTTS, Black Bess, and Phyllis, a reddish-coral self. 2nd, Mr. J. DOUGLAS, whose leading varieties were: green edges, Rev. F. D. HORNER, Abbé LISZT, Monarch, and seedlings; grey edges, George Lightbody, Ajax, and George RUISS; white edges, Magnie, Acme, Heather Bell, and Heather Bell; selfs, Mrs. POTTS, Sir Lancelot, and Heroine. Mr. A. J. SANDERS was 3rd.

The *Alpine Fandels*, as usual, were very bright and attractive. There were five collections of twelve varieties. Mr. C. TURNER, Royal Nursery, Slough, was placed 1st, having of gold centres Diamond Jubilee, Sunrise, John Beswick, Unique, and Charles Phipps; white centres, Countess, Belle Whitebright, Nellie, Mings, Metcote, and seedlings. This collection comprised some striking varieties. 2nd, Mr. CHARLES PHILLIPS, with varieties of his own raising, such as Vandyke, Little Gem, Hebe, and seedlings; the new sorts of this raiser being characterised by fine quality. Mr. J. HILL was 3rd. There were eight collections of six varieties. Mr. C. TURNER was again 1st, with E. Shaw, Sunrise, and Charles Turner, golden centres; Countess and Nellie, white centres. Mr. C. PHILLIPS was 2nd, with Mr. Gorton, Chastity, Vandyke, and Mrs. A. C. Bartholomew, golden centres; white centres, Gladly, and a seedling. With four varieties, Mr. W. L. WALKER, Reading, was 1st, with Ormonde, J. F. Kew, Ulma, and Defiance. Mr. J. J. KEES, Southampton, was 2nd, with seedlings.

Golden centres, as specimen plants, brought some good varieties. Mr. W. L. WALKER was 1st, with a very bright seedling; Mr. A. FISK was 2nd, with Hotsup; and Mr. J. GILBERT 3rd, with Mango Melon. In the class of white varieties, Mr. WALKER was 1st, with Thea, a maroon and purple-shaded flower, and 2nd with Defiance. Mr. GILBERT coming 3rd with A. J. SANDERS.

Fancy Auriculars were shown in twelve by the GUILDFORD NURSERY Co. and Mr. JAMES DOUGLAS. Rolt's Green Edge, with its red ground and green edge, an unusual combination, was prominent, also some very promising yellow selfs. Mr. DOUGLAS came 2nd, mainly with fantastic forms, which put in an appearance among seedling show varieties.

Polyanthus of the *Fancy* or *Giant* Type were shown by Messrs. A. J. SANDERS, J. DOUGLAS, and G. DIXON, Chelmsford, Cheshire. They were scarcely up to the usual standard of quality. It was so with the single Primroses, Mr. DOUGLAS was 1st, and Mr. SANDERS 2nd.

Double Primroses were poor. Mr. DOUGLAS taking the 1st prize, with decidedly the best, having the white, bluish, crimson, lilac, late yellow, and purple. The GUILDFORD NURSERY Co. were 2nd. Mr. DOUGLAS had the best baskets of Primroses and Polyanthus, the GUILDFORD NURSERY Co. again 2nd.

The classes for twelve and six species or well-marked varieties of Primroses, are always highly interesting, and if it is a pity they do not receive more entries. Mr. DOUGLAS was the only exhibitor of twelve, having in very good character verticillata, Forbesii, obconica, japonica, intermedia, floribunda, decora, mollis, and two varieties each of Sieboldii and Auricularia. Messrs. PAUL & SON, Chesham, were the only

exhibitors of a collection of six, having rosea, verticillata Forbesii, dentata, mollis, and a single flowered Primrose. The best group of six species or varieties of Primroses, Auricularia arranged in a box or basket, came also from Mr. DOUGLAS, distributed in a box with a surface of rocks and moss, at the back being such tall-growing subjects as Sieboldii, Forbesii, verticillata, and japonica, with intermedia decora, obconica nivalis and Auricularis, and Primroses in the foreground. The GUILDFORD NURSERY Co. was 2nd, having a round basket, at the back of which was a fine firm of Primroses, and in the foreground Auricularis of various types.

The Premier Auricular was green edge, the Rev. F. D. HORNER, with nine well developed pipes, one of the 1st prize twice exhibited by Mr. C. PHILLIPS.

NEW VARIETIES.

Several new varieties, show and Alpine, were staged in their classes. In that for pipe edges, Mr. J. DOUGLAS was 1st with Greenleaf raised by himself, and not to be confounded with Horner's Greenleaf of a few years ago; tube and paste good, black body colour and bright, deep-green edge. This was also awarded the Special Prize of half-a-guinea offered by Mr. W. Smith for a seedling green edge; and it received a Certificate of Merit also. A 2nd prize was awarded to an unnamed seedling of similar good qualities, exhibited by Mr. WILLIAM BALDWIN, Oxford Road, Reading, and this also received a Certificate of Merit. A bright maroon self, named Mole was shown by Mr. DOUGLAS, but it had the defects of a granulated paste and a defective outline. Certificates of Merit were awarded to the following new Alpines:—Ormonde (W. L. WALKER), golden centre, with a rich maroon and fiery crimson shading, very fine; Olivia (W. L. WALKER), pale cream centre, maroon, crimson, and delicate bluish shading; and Mrs. Markham (DOUGLAS), gold centre, with a dark margin shading to red. 1st prize was awarded to Mr. J. DOUGLAS for a gold-centred Alpine, Duke of York, maroon, shading to fiery crimson, very fine and bright; and a Certificate of Merit was also awarded. 2nd, Mr. C. TURNER, with gold centre Charles Turner, maroon, with broad shading of fiery salmon, smooth and fine. Mr. DOUGLAS also staged a very fine seedling, Mr. W. CENTRAL ALPINE, with red and Eros, maroon, reddish salmon, and pale mauve; and Mr. C. TURNER, the 2nd with Dora, maroon, with broad shading of mauve-pink.

BRIGHTON & SUSSEX HORTICULTURAL.

APRIL 6, 7.—The show held on the above dates was decidedly one of the best hitherto seen in Brighton in the spring, speaking of it as a whole.

Mr. G. MILES, Dyke Road, Brighton, was well to the fore in the large group class, which has generally been good at Brighton shows; Mr. E. MILES and Mr. G. MILES, of Brighton, Preston, was 2nd, but beating Mr. G. MILES in a special class for "mantlepieces decorated with plants and flowers." This competition proved an attractive one, that seems to be well deserving of imitation at shows elsewhere. Mirrors, shelves and fire-screens are provided by the Society, and I have seldom observed such showy exhibits in so small a compass.

Mr. H. GARNETT, gr. to G. FLETCHER Esq., Mount Harry, Preston, staged some good Orchids, the best being Dendrobium luhloenseanum, D. thyrsiformum, and 'Ypidium philippense.

There was a large number of classes for spring flowering plants, and the following are a few of the best contested. Mr. W. E. ANDERSON, gr. to S. COWELL, Esq., Melbourn, Preston Park, was 1st for twelve pots of Tulips; Mr. H. ANSCOMBE, Kemp Town Nursery, for twelve Hyacinths; Mr. A. G. GOLDING, gr. to H. S. VICKERS Esq., Dyke Road, for Lily of the Valley; Mr. J. HILL, gr. to M. WALLIS, Esq., Springfield, Preston, for Lachenalia; Messrs. W. MILES & Co., Church Road, Hereford, for Marguerites, Narcissus, Azaleas, and Lilium tuliform var. Harrisii; and Mr. H. NAYLOR, gr. to Mrs. MACDONALD, Preston, for some well-grown Greenhouse Azaleas. *Wintered groups* of plants were staged by Mr. J. HILL, gr. to M. WALLIS, Esq., Preston, being Mr. F. ITAPLEY, gr. to Miss VICKER, in the principal class. Some very fine cut blooms of Narcissus came from Mr. M. TOURLE, gr. to F. BARNHAM, Esq., Little Horsted, who staged grand bunches of Emperor, Sir Watkin, Beauty, Empress, Queen Sophia, W. Backhouse, Duchess of Westmeath, Mrs. G. Smith, Michael Foster, Madame de Graaf, conspicuous and grandis.

Some excellent non-competitive stands were put up; Messrs. BARR & SON, showing Narcissus in large numbers; Messrs. J. LAING & SON, Forest Hill, S.E. a very showy group of Palms, cacti, crotons, and other decorative plants, some good Clivias, and the Richarda Penlandii in better form than I have previously observed the plant. A good collection came from Messrs. BALCHIN & SONS; and cut Roses, Carnations and plants of Crisman Rambler from Mr. G. W. PIPER, The Nurseries, Uckfield.

THE SHROPSHIRE HORTICULTURAL.

APRIL 7.—The annual spring show of the Shropshire Horticultural Society, which took place in the Music Hall, Shrewsbury, on the above date, was a very successful one. The exhibition was well attended, and I saw many of its predecessors. This new departure worked most successfully, and the executive are to be congratulated on having brought it about. The display was a first-class one, and, as on previous occasions, the general effect was considerably heightened by the displays of the local florists and others.

MESSRS. FRITCHARD & SONS had an extensive stand of flowers and plants, which was quite a feature of the show. Their display of Cyclamens and Azaleas was excellent.

MR. E. M. REBEL, Shrewsbury, had a magnificent collection of flowering plants.

MESSRS. JONES & SONS, Shrewsbury, also made a display of floral designs in good taste.

MR. A. MYERS, Shrewsbury, received a special award for a beautiful lot of out Dahlgianiums, and a Silver-gilt medal was presented to Colonel R. T. LLOYD, Aston Hall (gr., Mr. R. C. Townsend), for a charming collection of orchids and other Roses.

MR. H. H. FRANCE-HAYBURY was also awarded a special prize for his collection of Anaryllis.

The other exhibitors in the non-competitive class were DR. KINGS, Limited, Chester, who had a splendid collection of Narcissus, and Mr. ECKFORD, of Wen, who showed a nice lot of Primulas, &c.

The competitive classes were on the whole of great excellence. The collections, both in the open and amateur classes, were highly meritorious.

The first prize in the miscellaneous collection was awarded to Captain PHILLIPS, Shrewsbury (gr., Mr. Geo. Burrows). This group formed one of the most attractive features of the show.

There was a fine show of Azaleas, Orléans and Cyclamens; Hyacinths, Richardus and Tulips were well represented, and some grand cut Roses were shown.

was 2nd. In the other amateur classes there were no entries.

Floral Decorations in Narcissus consisted of shower bouquets, arranged with Narcissus and suitable foliage, Mr. W. M. MILLS, the Curator of the March Cemetery, taking the 1st prize.

MR. W. G. PEERY had the best wreath, formed mainly of Trumpet Daffodils; Mr. MILLS was 2nd.

MR. MILLS was 1st with a very tasteful effect of Daffodils, they being employed with an excellent effect on a Marching stand; Mr. H. WILKS was placed 2nd.

Baskets of Narcissus were a very pleasing feature, the best coming from Mr. G. W. MILLER; Mr. R. W. GREENE, Wisbech, was 2nd.

Prizes were offered for six foliage plants, and Mr. J. KITTER, gr. to Dr. MYERS, Wisbech, took the 1st prize with very fine specimens of a glaucous form of *Araucaria excelsa*, a fine specimen of the variegated *Phormium tenax*, *Yucca aloefolia variegata*, and three others.

MR. MILLER had the best six flowering-plants—*Azalea*, *Cineraria*, *Cyclaea*, &c. Some capital *Calceolarias* were also shown, as well as some good low standards of *Azalea indica*.

Of other cut flowers, Tulips were shown in collections; also *Auricularia*, *Primroses* and *Polyanthuses*, *Pansies*, and boxes of cut flowers, gathered in the open, which contained many pretty subjects.

A special prize, offered for the best bunch or bloom in the show, was won by Mr. G. W. MILLER, with a bunch of fine blooms of *Narcissus Glory of Leyden*, finely developed.

SHIRLEY & DISTRICT GARDENERS'.

APRIL 7. A meeting of this Society was held on the above date, the President, Mr. W. F. G. SHANNON, presiding over a fair attendance of the members.

The Rev. G. H. ENGLEBERT, Appleshaw, Andover, gave a Lecture on the "Culture of the Narcissus," and his address was listened to most earnestly. First, he explained the characteristics of the several groups of Daffodils, and afterwards described the best soil for them, how to prepare the same, the best time to plant, &c. He spoke of the pleasure derived from growing Narcissus from seeds, with the constant expectation of acquiring something novel or interesting, and urged his audience to grow some plants from seed. He showed by some splendid blooms of Hybrid Narcissus, what may be done by cross fertilisation. A brief discussion ensued.

A hearty vote of thanks to the Rev. G. H. ENGLEBERT, both for his lecture and his exhibit was accorded him; and also to Messrs. BARR & SON, for an exhibit of thirty-five varieties of Narcissus blooms; to Mr. B. LADLAMS, for thirty varieties; and to Mr. W. H. ROGERS, Red Lodge Nursery, for an exhibit of hardy flowering shrubs and American plants.

WISBECH AND DISTRICT HORTICULTURAL ASSOCIATION — NARCISSUS SHOW.

APRIL 7, 8.—This was the second exhibition of this character, and as the entries had trebled in number, no more emphatic proof is required that the Daffodil is being cultivated in the district. The Exhibition, which was held in the Selwyn Hall, was opened by the Mayoress, and it was well attended during the day.

In the open classes, the leading one was for a collection of Narcissus, to fill an area of 16 square feet. There were several entries, and the flowers were arranged in bold and attractive bunches. Mr. G. W. MILLER, Wisbech, was 1st with a very fresh, bright collection consisting of the varieties Emperor, Empress, Capt. Nelson, Sanson, Sir Watkin, Glory of Leyden, some forms of the Barri type, and others; in all a good representative collection of about sixty bunches. Mr. A. W. WHITE, Spalding, was 2nd with a collection of some fifty bunches of finely grown leading varieties, and Mr. W. CROSS, 3rd, with six 4-distinct varieties of single trumpet Narcissus.

MR. G. W. MILLER was again 1st with glory of Leyden, Emperor, Empress, maximus, Mrs. J. B. M. Cann, and one other, all in fine character. Mr. A. W. WHITE was 2nd with similar varieties, and Mr. F. W. CROSS, 3rd, with twelve distinct varieties, five blooms each of the Incarnabilis, Briti, and Leobus sections.

MR. MILLER was 1st, having Figaro, Queen Bess, Cynosure, Paroissioschia, Mrs. L. Langtry, &c.; Mr. F. W. CROSS was 2nd with Cynosure—very good, Princess Mary, &c.

With four distinct varieties of Paeonies, Mr. MILLER was 1st, having Orot and Paeonius—very good; Mr. WHITE was 2nd. The best six double varieties also came from Mr. MILLER, Sulphur and Orange Phoenix being particularly good flowers.

Special Prizes were offered by Messrs. BARR & SONS for the best collection of Narcissus, in twenty-five varieties, and Best Mr. A. W. WHITE was 1st, placing in fine character Sir Watkin, Madame Plein, Emperor, Empress, Princess Mary, Hordfield, Dean Herbert, Mrs. Langtry, Orotinus, &c.; 2nd, Mr. G. W. MILLER.

MESSRS. DE GRAVE BROS., Leyden, Harland, offered special prizes for twenty bunches of Trumpet varieties, Mr. A. W. WHITE again taking the 1st prize, with fine character of Emperor, Hordfield, Dean Herbert, Madame de Graaf, Glory of Leyden, and other fine sorts.

In the amateurs' division, the best collection came from Mr. H. WELLS, the Secretary of the Society; Mr. H. E. NEW-

THE LATE COLONEL TREVOR CLARKE.

Obituary.

COLONEL TREVOR CLARKE.—Old Fellows of the Royal Horticultural Society will receive the announcement of the death of this famous horticulturist and lovable man with the deepest regret. He died on the 11th inst., in his 84th year. At one time, and, indeed, for many years, he was one of the most active members of the Society, having ever its truest interests at heart, and serving on the Council and on the Scientific Committee. To the latter body in its palmy days, his varied and extensive knowledge and his great experience as a cultivator were of the greatest service, and he had ever something new or interesting to exhibit. It was, in addition, to a cultivator and hybridiser, a botanist, a chemist, an entomologist, and a scholar; and those who were associated with him can never forget his quaint humour, his inimitable good temper, and geniality. In 1891, Colonel Clarke was a recipient of a Veitchian Medal, on which occasion we wrote the following note, which is as applicable now as then:

"Of late years we have not been privileged to see so much of him, but those who remember the Royal Horticultural Society, and the Scientific Committee some twenty years or more ago, will remember also how large a part Col. Trevor Clarke—he was Major then—played in all matters relating to scientific horti-

culture. He brought to bear the resources of science and of botany on horticulture, and was rarely without some interesting object to exhibit and comment upon. As a cultivator, Col. Clarke was very successful, and as a hybridiser and cross-breeder, and a selector, achieved much success, as witness the Celery called after him, and still in favour, and the very useful *Begonia Waltonensis*. But the most important work in which he was engaged was in cross-breeding Cotton, with a view to producing improved varieties. This necessitated, especially during and after the Cotton Famine, a long and exhaustive investigation into the natural history and methods of improving the varieties of Cotton of the genus *Gossypium*; and such was the success of his experiments, that a gold medal was awarded to him by the Cotton-supply Association of Manchester (and a special gift from the then Emperor of Russia). Many will remember at the South Kensington Exhibition of 1872, the house that was erected for the growth and display of various kinds of Cotton plants, and the very instructive exhibition therein arranged. Col. Clarke worked on the principle of taking the pollen from the wild forms, as nearly as he could do, and applying it to the Sea Island, New Orleans, and other approved varieties. The improvement was obvious, even in the first generation. Some details concerning this work will be found in our volume for 1872, p. 603 and p. 799; and a lecture by Col. Clarke himself was reported in our columns in 1865, p. 366. In Burbridge's *Cultivated Plants* is a list of over thirty hybrid *Begonia*s raised by Col. Clarke, and an abstract of his work in hybridising Cottons (p. 388).

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

The districts indicated by number in the first column are the following:—
0, Scotland; 1, Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. *Trinidad*, *Greenacres*, &c.; 6, Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending April 10, is furnished from the Meteorological Office:—

"The week continued very unsettled, with frequent rain in Ireland and the south and south-west of England;

lent in all the northern and eastern districts it was fairer than of late, and the rainfall slight. Thunder-storms occurred over the south of England on the 7th.

The temperature was below the mean in all districts, the deficit ranging from 1° in the Channel Islands to 4° over the northern, eastern, and central parts of Great Britain. The highest of the maxima were recorded either on the 8th or 9th, and ranged from 58° in 'Scotland, E.,' and 57° in 'England, S.,' and 'Ireland, S.' to 62° in 'England, N.E.,' and 'Scotland, W.' The lowest of the minima, which were registered on the 5th, were again very low for the time of year. They ranged from 16° in 'Scotland, E.,' and from 22° in 'Scotland, N.,' to 30° in 'England, S.,' 33° in 'Ireland, S.,' and 36° in the 'Channel Islands.'

The rainfall was much more than the mean in 'England, S.W.,' 'Ireland, S.,' and the 'Channel Islands,' and rather more in 'Ireland, N.' In the 'Midland Counties,' and 'England, S.' the fall just equalled the normal, while in all other districts there was a deficit.

The bright sunshine exceeded the mean over the north of England and the north and east of Scotland, and just equalled it in the 'Midland Counties' and 'Scotland, W.' In all other parts of the kingdom there was a deficiency. The percentage of the possible duration ranged from 43 in 'England, N.E.,' 42 in 'Scotland, E.,' and 41 in 'Scotland, N.,' and 'England, N.W.,' to 26 in 'Ireland, S.,' and 23 in 'Ireland, N.'

MARKETS.

COVENT GARDEN, APRIL 14.

CUT FLOWERS.—AVERAGE WHOLESALE PRICES.

Table with columns for flower types (Anemones, Arum, Azalea, Bouvardia, Carnation, etc.) and prices per dozen or bunch.

ORCHID-BLOOM in variety.

Table with columns for fruit types (Apples, Apricots, etc.) and prices per case or bushel.

VEGETABLES.—AVERAGE WHOLESALE PRICES.

Table with columns for vegetable types (Artichokes, Asparagus, Beans, etc.) and prices per bushel or bunch.

POTATOES.

Trade a shade firmer for good samples standing colour. Dumbar Maincrop, 75s. to 80s.; Saxons, 75s. to 78s.; Lincoln Saxons and Maincrop, 40s. to 70s.; do., Glenta, 45s. to 60s.; other descriptions, 30s. to 60s. John Beth, Hillingdon Street, Covent Garden.

PLANTS IN POT.—AVERAGE WHOLESALE PRICES.

Table with columns for plant types (Adiantum, Aspidistra, Azalea, etc.) and prices per dozen or specimen.

ROOTS FOR THE GARDEN in variety coming very good.

SEEDS.

LONDON: April 14.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., write that a fair number of consumptive orders for those seeds required for immediate sowing now comes to hand; these are executed at the low level of values characteristic of the present remarkable season. Choice samples of Grass and Clover seeds are just now obtainable at very tempting rates. France has been taking Alyska from England. Koenigsberg. Tares favour buyers. English Sunflower continues cheap. The new Niger and Sunflower seeds just landed, coming to a bare market, are in brisk request. For Hemp and Canary seed the demand is meagre. Mustard and Rape seed are strong. There is a rather better sale for Peas and Marrows. Scarlet Runners show no change. Linseed is firmer.

VARIORUM.

SKELETON LEAVES.—To skeletonise leaves, which, by the way, should be of mature growth, they must be macerated in rain-water for several weeks, turning them about carefully daily, and giving occasional rinses, or using a very soft brush, to remove the decaying matter. When the latter has quite disappeared, the undamaged skeletons should be selected from the imperfect specimens, and immersed in a very weak solution of common chloride of lime until sufficiently bleached, rinsed well in running water, and finally laid on a blotting-pal to dry. An effective way of mounting skeleton leaves is to fix them on a back-ground of dark-coloured velvet, and either make up into the form of a book or placed under a glass cover on an ornamental stand.

BOOKS: Bamboos, H. Papworth, New Orleans.—The Bamboo garden, by A. B. Freeman Mitford, C.B. (Macmillan & Co., Limited, London: Bedford Street, W.C.).—Mr. W. J. Bean's Classification of Dahlias, given in our pages in 1891-92, on February 10, 17, and 24; March 10, 21, and 31, with figures, might be of use to you. CARNATIONS: Clive. Certain varieties are apt to unkind their blossoms unkindly in early spring. It may be that the action is subjected to check. You appear to have given your plants correct cultivation, and future flowers will doubtless be perfect.

CLIVEA AFTER FLOWERING: J. Paton. If the roots are very tight in the pot, after the plant a larger pot, otherwise it will suffice to pick out the teert soil at the top and replace it with fresh loam, making this quite firm with the fingers. Do not use a rammer, the soft, fleshy roots being easily injured. Put the drainage in good order. Cliveas need plenty of water during the summer. The soil for repotting a plant may consist of turfy loam of good quality, one quarter of the whole rotted manure or leaf-mould, and one-eighth sharp sand. Do not shift into a pot that is more than 2 inches larger in diameter than the pot the plant grew in. Afford ample drainings of large crocks, and see that there is a close layer of turfy bits over the latter, to preserve good exit for the water, for at least two years. Keep in the greenhouse, or in July and August in a warm spot out of doors.

LAWN TENNIS COURT: C. W. You should send to Mr. Upcott Gill, Bazaar Office, 170, Strand, W.C., for his manual on the game. It costs only a few pence.

NAMES OF FRUITS: East Norfolk. Sturmer Pippin.—A. G. Wits. Rosemary Russet.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—F. G. S. Odontoglossum luteo-purpureum of the best type. Some of the varieties are very much inferior to this.—H. J. W. Dendrobium totile; easily determined by its twisted sepals.—R. T. Dendrobium transparens.—W. Moryze. Hoya multiflora—native of Malay Archipelago, not South America.—Jane Eyre. Forsythia suspensa.—A. Hills. Asparagus Sprengeria.—H. B. 1, Yanda cristata; 2, Dendrobium aureum.—W. P. Lincoln. 1, Davallia platyphyllo, often called Microlepia platyphyllo; 2, Pteris umbrosa; 3, Adiantum trapeziforme; 4, Adiantum tenerum; 5, Adiantum cardiochloa; 6, a variety of Adiantum capillus veeccis.—H. A superb variety of Dendrobium Falconeri giganteum.—W. L. Your hybrid Cypripedium seems to be between C. veauvanti and C. Hookeri, and is similar to that called C. x Cassiope.—J. P. P., North Britain. Broughtonia hiliaca, more generally called Lechlopiis dominicensis.—T. F., York. A similar variety is known as Dendrobium cobile giganteum. Yours are very finely coloured.—A. B. 1 and 2, both Oeodidium luridum guttatum; 3, Selaginella caulescens; 4, Selaginella umbrosa; 5, Selaginella Mertensii; 6, Crotocidia fulgida.—J. L. Lincoln. The moisture form of Adiantum gracillimum you have raised has also previously been raised. It is, as you say, a very pretty variety to use with out flowers.—T. B. and L. M. 1, Nephrodium molle; 2, Selaginella umbrosa; 3, Selaginella caulescens; 4, Selaginella caesia (the last three mosses); 2, Blechnum polydoides; 3, Nephrolepis exaltata; 4, Athyrium filix femina; 5, and 6, Gymnogramma ochracea, Gold Fern; 5, Pteris serrulata cristata; 6, Asplenium foveolatum; 7, Davallia bullata, the light green; 7, Davallia Tyermannii, the dark, thick frond. The specimens were mixed, and so we were unable to say which belonged to each set. Please, when sending again, have the numbers all different.—T. F., Edinburgh. We do not undertake name varieties of florists' flowers.—G. W. B. and G. A. Daffodils are now florists' flowers. We cannot undertake to name them. Send them to some grower.

NARCISSEUS: Ancionis Oure. There is yet time to dig the laud after dressing it with gas-lime before planting the bulbs. Instead of table Mustard, you should use the Mustard "dross," obtainable of the manufacturers. Between the rows of bulbs sow Mustard or Lettuce.

PEACH-TREE DEAD: E. E., West Cross. The soil seed seems to be of a healthy sort, and is not the cause of the death of the tree. Please send roots; their appearance may throw some light on the matter.

SALT ON ASPARAGUS BED: R. H. W. The quantity of salt too heavy a dressing by one-half to be given at one time; but the quantity of rain that has fallen of late may so lessen its effect on the plants that too harm may have been done.

SHOWING FOLIAGE PLANTS IN COMPETITION: Flower Show. The schedule says six varieties, and you would be within your right to show six Crotons, six Dracaenas, or six Palms, &c., but that is probably not the meaning that the schedule-framers intended to convey. It is six distinct genera, and we think that if you showed two species of Palms the judges would disqualify the exhibit.

VINE LEAVES: Enquirer. Too much humidity, and too little ventilation.

COMMUNICATIONS RECEIVED.—J. R. B.—W. P.—C. J. de B.—I. A. W., Burlington, U.S.A.—L. L.—G. W.—E. F., Ghent.—J. R.—H. B.—W. W.—K. J.—G. R.—E. A.—W.—D. T. F.—A. C.—E. W.—H. S.

SENDERS, PHOTOGRAPHS, &c., RECEIVED WITH THANKS.—J. R. (many thanks—often given)—D. T. F.—Letticher of files.

CONTINUED LARGE INCREASE IN THE CIRCULATION OF THE "GARDENERS' CHRONICLE." IMPORTANT TO ADVERTISERS.—The Publisher has the satisfaction of announcing that the circulation of the "Gardeners' Chronicle" has, since the reduction in the price of the paper, increased to the extent of more than 90 per cent., and that it continues to increase weekly. Advertisers are reminded that the "Chronicle" circulates among COUNTRY GENTLEMEN, and ALL CLASSES OF GARDENERS AND GARDEN-LOVERS at home, that it has a specially large FOREIGN AND COLONIAL CIRCULATION, and that it is preferred for reference in all the principal Libraries.

THE

Gardeners' Chronicle.

SATURDAY, APRIL 24, 1897.

AMELANCHIERS.

OF the numerous trees and shrubs now in flower, or rapidly approaching that state, few are so beautiful or attract so much attention as the Amelanchiers. It is not only the snowy whiteness and abundance of the blossom that arrest the eye, but the singular grace and lightness of the trees as a whole are scarcely rivalled by any other in flower at the same time. There are four species in cultivation, every one of which is valuable. They are as much to be commended for the smallest as for the largest of gardens, being of perfect hardiness, and thriving in any soil that is of average quality. The generic name is said to be derived from "Amelancier," the common name for *A. vulgaris* in the South of France. The only one of the American species well known in this country is *A. canadensis*, which, like *A. vulgaris*, is usually a small tree. Some of its forms, however, are purely shrubby, and this character pertains also to another American species — *A. oligocarpa*. These shrubby kinds are but little known, and as they are adapted for situations unsuited to the more tree-like types, it will be worth while, perhaps, to pass the genus in review, especially as the Western Shad-bush of North America — *A. alnifolia* — valuable on account of flowering later than the others, is also comparatively unknown. Besides their spring beauty, the Amelanchiers have an additional attraction in the rich autumnal colouring of their foliage. In sunnier climates than ours they are valued for their fruits, in the United States especially the native species are being cultivated for them alone, and promise to rank among the most useful of native fruits.

The following are the five species known; for the copious synonymy (*A. canadensis* alone has upwards of twenty synonyms) the reader is referred to the *Kew Hand-List of Hardy Trees and Shrubs* :—

- A. alnifolia*, North America.
- A. canadensis*, North America, China and Japan (syns. *A. Botryapium*, *A. asiatica*).
- A. oligocarpa*, North America.
- A. vulgaris*, Europe.
- A. parviflora*, Asia Minor.

A. CANADENSIS (THE JUNEBERRY).

In many respects this is the finest of all the Amelanchiers, growing to greater size than any, and reaching in this country heights of 20 to 40 feet. In North America, specimens have been found 50 feet high, with trunks $1\frac{1}{2}$ to more than 2 feet in diameter. On the other hand, it is often a mere shrub only a few feet high. It varies considerably in time of flowering, some trees being past before others are in full beauty, but the average date

is the second and third weeks in April. The leaves are ovate, more or less pointed, frequently cordate at the base, finely toothed, and on first opening are covered with a greyish-felt beneath, but afterwards become nearly smooth; they vary in length from $1\frac{1}{2}$ to 3 inches. The flowers appear in racemes, 3 to 5 inches long, and are pure white; the strap-shaped petals about three-quarters of an inch long. Its fruits are produced every year at Kew, and are globose and of a purplish-red. It is one of the freest flowering of all hardy trees, and each spring is a mass of white; the thin, graceful habit, together with the elegance and lightness of the racemes, give it a charm few others surpass. This species has a wide distribution in Eastern North America, stretching from Newfoundland southwards to Florida. It shows, in consequence, much variation in size and mode of growth, as well as in the characters of flower and leaf. Many of the varietal names that were given to these different forms are no longer retained. The following variety, however, has been considered sufficiently distinct to stand :—

Var. oblongifolia.—As represented at Kew, this is a dwarf shrub, 3 to 4 feet high, producing suckergrowths like a *Spirea*, enabling it to be propagated by division. Its leaves are broader than those of the type, and not so distinctly toothed; they are also more tomentose. The flowers are in shorter racemes, and are individually smaller. The plant is of sturdier growth, and will flower when under one foot high. In a state of nature it does not reach so far to the south as the ordinary *A. canadensis*, being found chiefly in the north-eastern United States, and in Quebec and Ontario. A group of about a dozen plants flower every spring in the collection of Rosaceae at Kew a fortnight later than the type. It is rare at present, but well deserves an extended cultivation; in the United States it is greatly valued for its fruits, and is popularly known as "Success" Juneberry.

The Amelanchier, found in Japan and China, and known as *A. asiatica*, is included under this species by several botanists, including Maximowicz. As a cultivated plant little appears to be definitely known about it, but specimens in the Kew Herbarium, gathered by Dr. A. Henry and by Dr. Faber in China, show the same leading characters as the American *A. canadensis*.

A. ALNIFOLIA (WESTERN SHAD-BUSH).

This is a native of Western North America, and was at one time regarded as a geographical variety of *A. canadensis*. It is now generally held to be specifically distinct, although some of the forms at the eastern limits of its distribution (and it reaches as far east as the Great Lakes) closely resemble *A. canadensis*. It is, in rare instances, a tree over 30 feet high; but, as a rule, is a small tree or shrub, 6 to 12 feet high, of more erect growth than *A. canadensis*. From that species it is, when in leaf, easily distinguished by the broader, shorter leaves, the teeth of which are much coarser, and confined to the terminal part, the margins at the base being quite entire. It flowers in May (and thus later than the other), the shorter, denser racemes bearing flowers 1 to 2 inches in diameter. Its flower is scarcely so ornamental as *A. canadensis*. The fruits are larger than those of that species, measuring occasionally nearly 1 inch in diameter; they are of a purple or almost black colour, and covered with a glaucous bloom. In a wild state their edible quality varies greatly, but at their best they are very sweet and juicy. David Douglas was the first to introduce this species to Europe, sending it home, according to Lindley, in 1826. It had, however, been known as long before as 1801, when the first overland journey from the Atlantic to the Pacific, in high latitudes, was made by the expedition under Lewis and Clarke, the members of which found the fruits of this Shad-bush in great quantity, and a great help to them when food was scarce.

A. OLIGOCARPA.

Of the American species this is the rarest in cultivation. Unlike the two just described, it never becomes a tree, and rarely exceeds 4 feet in height. The leaves are glabrous, except when quite young, oblong, and sharply toothed. The greatest distinction between this and the other Amelanchiers is in the mode of flowering. It does not produce its blossoms in racemes as they do, but singly or in pairs (rarely in threes or fours), on long stalks from the nodes on the whole length of last year's wood. A plant at Kew, which this year was the earliest of all the species to flower, produced them chiefly in pairs, each about one inch in diameter, with pure white, obovate petals. The fruit is obovate, of a dark purplish-blue, and is said to have a sweet and more decided flavour than that of *A. canadensis*. Very few plants of this promising shrub exist in this country, but it is to be hoped it will soon become more plentiful. It does not extend so far south as the other American species, being confined to the North United States and Canada, where it inhabits swamps and mountain bogs. In spite of this it thrives in rich and ordinarily moist soil, and improves under cultivation.

A. VULGARIS (THE SNOWY "MESPILUS").

For over three hundred years this, so-called "Snowy Mespilus," has been cultivated in England. It varies in size from a small tree, 15 to 20 feet high, to a shrub one-third that height. Its leaves, like those of *A. canadensis* (which it much resembles) are very downy beneath on first opening, but soon become smooth; they are roundish oval, serrated (especially towards the apex), and vary in length from 1 to $2\frac{1}{2}$ inches. It produces its pure white flowers in racemes, which appear in great profusion during April, followed by black-purple fruits about the size and shape of a Black Currant. This species is a native of Europe, and is one of the lowliest of the small trees or shrubs found at the middle elevations of the Alps and Pyrenees. It reaches eastward as far as Crete and Dalmatia, where the more pubescent, shrubby var. *cretica* appears. Of the other so-called varieties, that named *integrifolia* is, perhaps, the most distinct, its leaves being quite entire.

A. PARVIFLORA.

Little has to be said of this species at present. I have not seen it alive, and am not aware of its being in cultivation in this country. It is one of Boissier's species, and is a native of Asia Minor. The following description has been made from dried specimens :— Leaf elliptic or obovate, usually less than half-an-inch long, slightly serrate, petioles adnate under surface thickly covered with whitish tomentum. Flowers a little over half-an-inch across, with obovate petals, and produced in short racemes 1 to 2 inches long. It is apparently a shrub. *W. J. Bean, Kew.*

NEW OR NOTEWORTHY PLANTS.

ODONTOGLOSSUM RUCKERIANUM
OCCELLATUM.

I HAVE long thought that the so-called *O. Ruckerianum* was none other than a form of *Andersonium*, named by Prof. or Reichenbach nearly thirty years now, and my impression is confirmed by the excellent materials before me, taken from a plant in flower in the collection of William Thompson, Esq., Walton Grange, Stone, Staffordshire, which was exhibited at a recent meeting of the Royal Horticultural Society. The form is precisely similar to that of the original named plant, showing the pretence of crispum and odoratum, and the size of the segments is greatly increased, and the colouring matter more pronounced and more beautiful, yet quite unworthy of specific distinction. If priority is to be regarded, this and all *Ruckerianums* must be relegated to *Andersonium*.

The sepals are somewhat sagittate, the standard one being the best formed of the three; ground colour flushed rose, clear and with crowds of solid chocolate spots, varying in size. The petals are ovate-acuminate, wavy towards the edges, and with a whitish ground

colour from the base to two-thirds of their length, and flushed towards the spear-like point. The spotting here is more minute, and a little less plentiful than upon the other limbs, but the chestnut colour is equally high. The lips conspicuously broad at the base, contracting towards the centre, and expanding at the extremity. A fine shade of yellow is planted in the calli, shading out to bluish-white, with a single large chocolate blotch right in the centre of the limb, with a few subsidiary spots on the shield. The convex colour stands boldly in relief. For richness of colouring, shading, and spotting it comes nearest to *O. crispum* Ashworthianum, showing those rare vagaries which so seldom come to us from a native habitat. The plant was bearing seventeen flowers on a branched spike. *J. Anderson.*

ORCHID NOTES AND GLEANINGS.

ORCHIDS AT WALTON GRANGE.

THIS place is situate near the town of Stone, on the banks of the Trent, and is owned and tenanted by William Thompson, Esq. (Mr. Stevens, gr.), whose chief hobby for the last thirty years has been the cultivation of Orchids. His gardener has been with him for that long period, and has had the knack of cultivating that interesting family to some purpose. It is quite fifteen years since the writer last visited the place, along with the late Zadok Stevens, of Trentham. Then it was remarkable for many things, intropical and cool. *Odontoglossum* were always a feature, but *Dendrobiums*, *Cattleyas*, *Masdevallias*, and all showy species were also well cared for, together with many other species that one does not find in general collections. Now the same classes of plants are conspicuous, and most of them show the careful hand of cultivation. More than that, the collection has been carefully weeded out, so that nothing but of sterling value and prepossessing appearance remains. The houses, which have been increased as occasion required, are neither large nor lofty, with the exception of one that, in older times, had been used for conservatory plants. They have no pretensions to exterior grandeur, but appear to have been constructed for the well-being of the plants they contain. There is plenty of light; the heating-apparatus is arranged intelligently; opportunities exist for obtaining atmospheric moisture, and for giving ample ventilation. The roofs are not lofty, yet most of the houses are comfortable for walking in.

Odontoglossum are the chief feature, and a most remarkable display of racemes and spikes met the eye during our visit. It is impossible to find a better grown and flowered batch of those quaint forms, where a mixture of brown, fawn, chestnut, Indian-red, various shades of yellow and white, get commingled, such as we see represented in *Lutrix*, *luteo-purpureum*, *septrinum*, *Cordilini*, *Wilkeanum*, which has been reproduced here by crossing. This is a beautiful form, the shaded yellow, as if it had been dipped in melted butter, being very striking, with its three chestnut orbicular spots placed in the centre of the nicely-formed labellum, showing a mixture altogether of the parents, *triumphans* and *Pescatorei*. *O. dilatatum* was a picture, with its straight stout spike of thirteen flowers, in which the whole of the segments are of similar oblong form, and stand along with the lip on a plane. The grand racemes of *O. Halli* towered above their neighbours, and in that show-house alone there would be 200 spikes of that particular division of *Odontoglossa*. Of course, *O. crispum* is strongly in evidence, and so is *O. Pescatorei* in some beautiful forms; and numbers of *O. Andersonianum*, varying in ground colour from white to a mixture of lemon and yellow, some profusely spotted, others only partial. This house would be 70 by 12 feet.

Another one of similar size standing at right angles is equally noteworthy. We must not omit to note a magnificent specimen of *O. novium majus*, with quite twenty buds, and promising a fine crop of bloom

In this house, too, is growing in tubular rafts *Vanda Kimballiana*, and also *V. Amesie*, both enjoying the cool moist atmosphere. The linear-bulbed *Dendrobium*, *D. longicornum*, is in the pink of health, showing that infundibulum, Jamesianum should not be coddled in heat. *Masdevalla Shuttleworthii*, with dozens of flowers with a singularly beautiful yellow-rayed standard, points to this as one of the chief of the colour. It is long since we came across *M. ignea violacea*, which, with a well-developed ignea by its side, showed a striking contrast. In a span-roof-house about 30 by 40 feet were some of the specimen *crispums*, and grand plants they were, with roundly-ovate plump pseudo-bulbs. One named Alfred Thomson, with ten great bulbs, was conspicuous. *Odontoglossum hastilabium* was a giant in growth and spike, doing fine along with a superb collection of *Laelia anceps* in all its forms and colours.

The *Cattleya bonae* is 60 feet by 16 feet. The quantities of flowers of *C. Schroderi*, and the great variety of shades, together with their sweet fragrance, command attention; the white and intermediary shades contrast well, and the brighter labellums of many of the forms of *C. Trianae* cast a glow over the house. The *Laelias*, too, were in evidence, the plant of the Waltham Grange form of *Laelia tenebrosa* being still unique.

FIG. 89.—*SOPHRONITIS GRANDIFLORA*.

Miltonia vexillaria had a good portion of a house to themselves, not over-heated, and scrupulously clean, showing, with their strong growths, what an abundance of fine flowers would in time be evolved. The beautiful paper-white *Masdevalla tovarensis* is also in this house, and without a flaw, as well as a group of *Odontoglossum Harryanum*.

Cypripediums are grown in a limited overhead climate, and nothing was more striking amongst them than a giant form of *Rothschildianum*. Some of the rarer lots, such as *Lawrenceanum Hysenau*, was noted, and others of the yellow insigne finish, the house measuring 20 by 10 feet, being filled with an assortment of the best slips.

Dendrobiums are in great variety, generally suspended from the lofty roof of the old conservatory. Some of the forms of noble are beautifully coloured, and the best of the more recent hybrids have been secured.

A convenient room has been constructed for Mr. Stevens, who keeps a set of periodicals for reference, and not the least pleasant half-hour we spent was in company with Mr. Thompson and his gardener, turning up the plates of plants, rare and beautiful, many of which have flowered from time to time in the Walton Grange establishment. *J. A.*

DENDROBIUM AMBOINENSE.

A plant of this rare and singular-looking species is in flower in the collection of Major Joicey, Sunningdale Park, Sunningdale. The large, creamy-white flowers come in pairs. The remarkable lip, which, small in proportion to the size of the flower, exhibits but slight trace of a spur at the base, is folded over the short column; the front of the lip is prolonged into a narrow, slender point, which in colour is reddish at the edge; the base of the lip is yellow, marked with brown, and is furnished with an orange-coloured tubercle and several pairs of smaller ones. Mr. Thorne, the gardener, had to remove it from one house to another before he found the right place for it, which is one that is tolerably warm and rather humid.

LAELIO-CATTELEYA × DIGBYANO-TRIANAEL.

We learn that this fine hybrid, which was first exhibited by the raisers, Messrs. J. Veitch & Sons, Ltd., at the last meeting of the Orchid Committee of the Royal Horticultural Society, has passed into the collection of Sir Frederick Wigan, Clare Lawn, East Sheen. Mr. W. H. Young, Sir Frederick's Orchid-grower, considers that in consequence of the freedom with which one of the parents—*C. Trianae*—grows, the cross will form a close rival to *L. C. × Digbyano-Mossiae*.

LAELIA × LATONA (L. CINNABARINA × L. PURPURATA).

Several plants of this fine Veitchian hybrid are at the present time in flower, and two matters noted about them are that, as they increase in strength, the intensity of the purple and orange-velvet tints in the flowers become more pronounced; and it is noticeable that the colouring of the lip differs in different plants. The first plant to show flower had a lip of purple, with a rose and yellow-coloured tip; and each succeeding variety that has flowered displays the same characteristic in some degree—whilst the latest to flower, which is also the strongest, has a lip of rich purple throughout. This plant has six flowers on a spike, which is the highest number borne by it, though there is reason to suppose that more will be produced.

SOPHRONITIS GRANDIFLORA.

Our illustration (fig. 89) of this much-admired winter-flowering species, taken from a photograph kindly sent us by Mr. Ernest A. Tucker, of Vernon Lodge, Preston, Brighton, exhibits two plants, one growing on a piece of wood as imported, and bearing thirteen flowers; the other, in a basket, has six flowers. The flowers of the latter plant, Mr. Tucker tells us, differ in shape to those of the former, and are not of such intense shade of scarlet. *Sophronitis grandiflora* is a native of the Organ Mountains, Brazil, and is the finest of the genus. Its deep crimson-scarlet flowers appearing in November, December, and January, they help to decorate the cool Orchid-house during the gloomiest months. There are two varieties of *S. grandiflora*, one having short obtuse leaves, and very brilliant-coloured blossoms; the other with rather longer leaves and pseudo-bulbs, which some regard as being the same as *S. coccinea*. The plants do equally well in baskets, or secured to blocks of wood in the usual manner.

BASIC-SLAG AS A GARDEN MANURE.

ALTHOUGH basic-slag is now a familiar substance amongst farmers, it is a fertiliser which is rarely used in gardens; but we have found it to be well adapted both for pot-culture, the kitchen and the flower garden, as well as the lawn. Moreover, since it is the cheapest source of phosphate we possess, it is worthy the attention of market gardeners and nurserymen. It has advantages also which no other phosphatic-manure possesses.

The phosphate in basic-slag does not dissolve in water like that in superphosphate of lime, and it is therefore not so suitable for top-dressing as the latter. But 35 per cent. of the phosphoric acid in

basic-slag is soluble in an aqueous solution of carbon dioxide. But soils which are rich in vegetable matter evolve considerable quantities of carbon-dioxide gas owing to the decomposition and oxidation of this organic matter, hence we find that basic-slag is especially adapted for peaty soil, and for kitchen garden soils which have been for years liberally treated with dung. Turfy-loam, which is so much used for potting, also contains much vegetable matter, and very little available phosphate is present; now, the usual practice is to mix bone-manure with this turfy-loam, but we have found that better results are obtained with basic-slag, and at much less cost, provided that the plants receive also a little nitrogen in the form of liquid, either a very dilute solution of urate of soda or of ammonium sulphate—but this addition is not always required. Indeed, there is much advantage to be gained by mixing the phosphate with the soil, and only giving the nitrogen when the plants require it. An excess of phosphate in the form of basic-slag will not do any harm; it will not produce rank sappy growth, and it is not washed out of the soil. But an excessive dose of rich nitrogenous manure is never profitable, and may often do much harm; it causes great leaf-development, and retards ripening.

Basic-slag, as its name implies, is *basic* in its reaction; that is, it neutralises free acids, and since soils which contain much vegetable matter or humus are frequently acid, basic-slag neutralises this acidity by reason of the lime which it contains. Superphosphate is an *acid* manure, containing soluble acid phosphate, and although it is a valuable fertiliser, it should not be added to a soil which is already acid. If Turnips, Cabbages, or Cauliflowers are attacked by "finger-and-toe" or "anbury," they are always worse if the land has been dressed with superphosphate, the reason apparently being that the spores of the fungus germinate more readily in an acid medium. But the above named plants require a ready supply of soluble phosphate if they are to thrive well; therefore, if the land is infected with finger-and-toe, and if the planting of Cruciferous plants is unavoidable on the infected land, do not use superphosphate, but use basic-slag.

The effect of basic-slag is like that of superphosphate when it is applied to lawns—it causes White Clover to be more abundant, and it tends to remove moss.

Most crops are benefited by basic-slag, but particularly Beans and Peas. We have carried out several experiments on market-gardens, using different manures on Peas and on Beans, and we have always found this manure to be useful; the increased crop obtained by its use has paid for the outlay on the manure several times over. Phosphates, when applied to these crops, cause an earlier maturation to take place, and this fact is an important one in the case of early Peas, and also when French Beans are forced. Nitrogenous manure, on the other hand, may cause the crop to be late; these leguminous plants can obtain sufficient nitrogen from the atmosphere, so that if we supply them with sufficient available phosphate and potash, they will not need any other manure.

The amount of phosphoric acid in basic-slag varies considerably. It ranges from 5 to 20 per cent, which is equivalent to a range of 11 to 44 per cent, of tricalcic phosphate; this is partly owing to the differences in the amount of phosphorus in the iron ores, and also to variations in the amount of lime which has been added to the molten metal in order to remove this phosphorus. All the slag which is sold as a manure is not basic-slag; recently a sample of slag came under my notice which was being sold for 50s. a ton; it did not contain a trace of phosphoric acid, or any other fertilising substance, and was, indeed, not so valuable as an equal weight of coal-ashes; it was in reality an "acid" slag, and quite valueless.

Basic slag should be ground to an impalpable powder, so that most of it will pass through the standard sieve, containing 120 wires to the linear inch. It is a disagreeable manure to spread evenly on the garden, especially on a windy day—it is blown about

easily, and soon makes one as black as a sweep; in order to avoid this inconvenience, it is better to mix it with some fine damp earth previous to spreading it. It must not be mixed with ammonium sulphate, because the lime in the slag would displace the ammonia and cause a serious loss.

The average amount of phosphoric acid in this manure is about 17 per cent, and of this a dressing of 3 or 4 oz. to the square yard is enough. Its effects are appreciable for two or three years. F. V. Dutton. University College of North Wales, Bangor.

THE ROSARY.

THREE NEW CLIMBING ROSES.

SINCE CRIMSON Rambler proved itself to be such a generally valuable form of the Japanese *Rosa polyantha sermentosa*, three new varieties, raised by M. P. Lambert, of Trèves, have already obtained well-deserved attention. They bear the names of the three Graces—*Aglaia*, *Euphrosyne*, and *Thalia*, and appeared simultaneously. The plants flower on the ripened long shoots of the previous year, exactly as does *Crimson Rambler*, and in bunches of from 30 to 100 blossoms, which expand slowly in long succession. These varieties are not chance seedlings, but the result of artificially crossing *R. polyantha sermentosa* with other varieties, and they differ not so much in habit of growth as in the colour of their small half-opened flowers. Those of *Aglaia* are light greenish-yellow, fairly double, of the size of *R. Gloire des Polyantha*, of a cupped form, and Tea-scented; whilst those of *Euphrosyne* are clear rose, and in the bud-stage bright light carmine-red. The flowers of *Thalia* are clear white.

ROCKERY SHRUBS.

THE vegetation of high mountains always manifests, even with shrubs and shrubby plants, the stunted and compact habit characteristic of the alpine flora. On large rocks, especially in the alpine garden, dwarf and trailing shrubs and rock-growing bushes can be arranged so as successfully to suggest a mountainous group. I will mention some species which are especially useful for this purpose.

To begin with, there is the whole series of *Ericas* and *Vacciniums*, known and grown in England better than with us. The genus *Audromeda* yields many varieties elegant in form, with delicate blooms of different colours. *A. corymbata*, *japonica*, *polifolia*, *fastigiata*, *tetragona*, and *hypnoides*, though widely known in England, are but little grown on the Continent.

Ericas, generally silex-loving plants, do badly in our country, where Jurassic and calcareous soil is found; but very well in England. *E. carnea* is an exception. It is excellent on sunny rocks, grows on calcareous or siliceous soil, and is gay in early spring in our Vaucluse mountains, whence it grows down into the plain, cropping up between the rocks and stones, and showing everywhere its very bright rose-carmine blossoms. These flowers last a long time; in a full south position on my rockery I have a large clump of *Erica carnea* which bloomed in mid-January, and is still in full beauty. At the foot of a wall and full south it blooms until Christmas.

Vaccinium and *Oxycoccus* are also silex-loving plants, and found in full beauty along the shores of the Atlantic. But the *Arbutus* is one of the best shrubs for the alpine garden from a decorative point of view. I refer to our *Raisin d'Ours*, *Arctostaphylos Uva-Ursi*, which bears long and full branches trailing on the ground. One plant will sometimes cover four or five square metres. The foliage is persistent through the winter, is dark, dull green, thick and coriaceous; mingled in spring with numerous trusses of rose-coloured flowers, which are succeeded in autumn by bright red berries.

But alpine *Rhododendrons* are among the most valuable of our shrubs. There are three or even four; among them *R. ferrugineum* and *R. hirsutum* are easy to grow, while *R. intermedium* and *R.*

Chamaecistus—the latter beautiful, elegant, with large, clear rose, *Cistus*-like flowers—are very difficult. Like *R. kamtschaticum*, this latter *Rhododendron*, found in the mountains of Tyrol, is grown in porous soil, rich in vegetable humus, and in full sun. In Geneva we can only grow it in pots of sphagnum. *Rhododendron* growers and raisers should notice this species, and increase it in gardens.

Atragea alpina, a *Clematis*-like plant, with violet-blue flowers, grows wild in copses and woods on chalky slopes among the Alps. It is not common, for its flowers have attracted attention, and reckless gathering has destroyed it in many localities. Thus, at Salève, near Geneva, its only habitat in this district, it has ceased to exist for the last ten years, amateur collectors having taken all, or bought it from flower-sellers in the market. Happily it grows readily from seed or graft, and is growing with various horticulturists. There are varieties with pure white or red flowers which also are cultivated, as *Atragea sibirica*, *genioia*, and *Wunderlichii*. These like partial shade, leaf-mould, and but little interference, as the less they are moved the more they flourish.

Among plants which grow and get lost is the charming *Betula uva*, with leaves shining, round, elegantly-crenulate, with slender, plant branches, and light and delicate habit. It is scarcely 3 feet high, and a great ornament to a rockery. *B. uva* was formerly plentiful, but is now scarce in this country, except in certain boggy places of the Jura plateau, and there it is so poor that it can hardly be said to exist at all. It shares, in fact, the fate of the marsh-flora, which is diminishing under cultivation and the search for peat. But the dwarf Beech still abounds in Polar regions, covers the slopes of the North Cape and the Scandinavian Alps, where it shades the delicate *Diapensia lapponica*. In cultivation it prefers a fresh deep soil and slight shade. It is increased by slips and seeds.

Ephedra helvetica is a curious plant which is found on old walls and the moist arid rocks of Canton Valais. It is one of the features of what is known to us as the flora of the "xerothermic" period. It has the peculiar appearance of *Equisetum*, but is not so leafless-looking, as in spring the male plants bear yellowish-green catkins, while in autumn the female plants have bright red fruits or berries, something like those of *Yew*, *Ephedra* being, in fact, closely allied to *Conifers*.

The existence in our country of a plant which clearly originated in the steppes, and most of the congeners of which, grown in the Asiatic and African deserts, has given rise to much discussion. It is certainly a relic of the flora of a "xerothermic" period which succeeded that of the melting of the glaciers, and its presence among our Valais Alps indicates a climate alternately hot and cold, dry and windy. This curious little shrub, placed in the full sun, soon spreads from a niche or fissure, and its brilliant berries are, in autumn, a great ornament to the alpine garden. There are many other *Ephedra* which also grow in rocks, and are very decorative. There are the foreign species, *E. alata*, *altissima*, *anthera*, *campanuliflora*, *distachya*, *fragilis*, *monostachya*, *nevalensis*, and *trifurca*, which are hardy in our climate.

Anemone vulgaris is a charming shrub, growing in the chinks of calcareous rocks in full sun, and the stems of which arch gracefully, and are at this season covered with large white flowers, rose-coloured outside, and hanging in axillary clusters. The plant sometimes grows nearly 10 feet high. *Cornus canadensis* and *suecica* are small shrubs with large flowers, which like a sunny position and a peaty soil.

Among the genus *Daphne* we find many acceptable and delicately perfumed plants. *D. Genkwa*, growing on calcareous soil in the Jura and Southern Alps, and also in Hungary and Transylvania, is the best of all; its pretty rose-coloured flowers in little close clusters scent our rocks in May and June, and sometimes again in the autumn. In firm and heavy soil it succeeds better than in light, and sometimes grows to a considerable size; a sunny situation is preferred. This *Daphne* is known to us as "Thymelée de

Alpes," or "Perles des montagnes." There is one variety with large flowers, another with white flowers and variegated leaves. *D. striata* and *Verlotii* are forms of *D. Cœornia*. *D. Blagayana* from the Carionian and Styrian Alps is a small shrub with decumbent stems, broad persistent oval-oblong leaves, glaucous-green with large cream-white flowers in clusters, and fragrant, opening in March and April; it requires semi-shade, and a porous, well-drained soil. *D. alpina* is a small, stunted bush with tortuous branches, leaves at the summit only, flowers yellowish-white, slightly scented, and succeeded by bright brick-red berries; it requires a calcareous stony soil and full sunshine.

Rhamnus alpina, *pumila* and *saxatilis*, which like chicks in the rock in the full sun; also the alpine willows (*Salix herbacea*, *retusa*, *reticulata*, *serpyllifolia*) have decumbent stems flat on the ground or only a few inches above it, and are also very pretty for alpine rockeries. *H. Correvon*, *Jardin alpin d'Acclimatation, Geneva*.

ODONTOGLOSSUM CRISPUM VARS. LUCIANI AND LINDENI.

Our illustrations (figs. 90 and 91), for which we are indebted to the courtesy of MM. Linden, represent two varieties of *Odontoglossum crispum* for which the establishment of the Messrs. Linden, Parc Leopold, Brussels, has of late years been noted. Fine examples have been exhibited at the Royal Horticultural Society's meetings, and have been rendered familiar to us by the illustrations of some of them in the *Lindensia*, and especially in the *Odontoglossum* number, in which eight fine varieties were illustrated, the issue appearing in June, 1896. Nor are the beauties of these fine flowers a barren possession commercially, for the fashion in value was set by fine *O. crispum angustum*, for which Messrs. Linden obtained a First-class Certificate at the last Temple Show, and which was illustrated in the *Gardeners' Chronicle*, May 23, 1896, p. 649. That plant was said to have had more than one offer for it up to 300 guineas, at which price it was sold, and those illustrated now were rated at the same value. The *O. crispum Luciani* (fig. 90), which variety, when the small plant that obtained a First-class Certificate at the Royal Horticultural Society's meeting on March 23, this year, has had time to develop, will assuredly be a noble variety. It has very fine flowers, white, tinged with rose and blotched with purple-brown; and *O. c. Lindenii* (fig. 91, p. 269) is also a handsome and distinct variety, as a glance at our illustration of the bloom shows.

GARDENING IN RUSSIA.

(Continued from p. 249.)

NURSERIES.—Another important nursery in St. Petersburg is that of Messrs. Regel & Kesselring, which, since the death of the never-to-be-forgotten elder Regel has been carried on in the same manner by his son-in-law, Mr. Kesselring; whilst contrariwise the St. Petersburg Botanical Garden has sunk in the few years that have elapsed since Regel's death, from a garden of the foremost rank to a simple flower-garden in which carpet-bedding plays the chief rôle. If the botanical garden should continue to decline at the present rate, botanists will, in the course of a few years, merely have the remembrance that there once existed a most valuable collection of plants second only to that at Kew.

I served under Regel in the St. Petersburg garden for a period of four-and-a-half years, and was therefore well acquainted with it, and it saddened me to remark how much it had declined; it however did me good to visit Regel's tree nursery. Those who suppose that shrubs and trees alone are to be found here are mistaken, although the collection of these is a very rich one; but still richer is the collection of herbaceous perennials, of which about 2500 species and varieties are grown in the open ground. Shrubs number 750 species, fruits about 4000. It would take up too much space if I were to enumerate all the novelties which I saw, and to do so is uncalculated for, seeing that all the names and descriptions are to be found in the nursery list. Only a few novelties—about 300—are not found in this list, and

therefore, not for sale. Taking them as they appeared in the borders, I may name the following:—*Dianthus Sternbergi*, *Diphyllea cymosa*, *Gentiana phlogifolia*, *Ledum glandulosum*, *Veratrum Maaki*, *Adonis wolgensis*, *Primula pseudo-Försteri*, *Lilium Glehni* and *L. cupreum*, *Lychium lapponica*, *Cerastium Rocheliana caryophylla*, *Authemis Aizooi*, *Saxifraga Lercheufeldi*, *Lilium avenaceum*, *Dianthus tener*, *Ranunculus bilobus*, *Saxifraga Alberti* and *Thom-beana*, *Spirea bullata*, *Cousinia Schtchurovskiana*, *Laptisia leucantha*, *Anthericum undulatum*, *Gentiana Regelii*, *Epimedium colchicum*, *Lophanthus chinensis*, *Aquilegia Baulhii*, *Mimulus primuloides*, *Azaleastrum purpureum*, *Iris Alberti*, *Fœonia banatica* and *fulgida*, *Rubia cordifolia*, *Rubus crategifolius*, *Aralia nudicaulis*, *Salvia Regeliana*, *Artemisia amurensis*, *Iris orchoides*, *Corydalis decipiens*, *Crocus cilicicus* and *carpetanus*, *Tanacetum leucophyllum*, *Inula cusifolia*, *Kitabelia vitifolia*, *Hugueninia tanacetifolia*, *Thom-*

The general has a partiality for Cycads and Palms, and is the possessor of a very fine collection of these plants, such, indeed, as can only be found in some of the more extensive botanical gardens, no fewer than 207 species of Palms and 68 species of Cycads being represented. Besides these, his glasshouses contain numerous choice plants, as, for example, a large collection of *Acacias*, *Bromeliads*, *Conifers*, and *Crotons*.

The collection of Orchids is also considerable. Another notable garden is that belonging to Mr. Pasterechov, in which I observed a large number of strong plants of *Onvandra fœnestralis*. The Palms and Orchids there are also very fine.

IMPERIAL GARDENS.

The Imperial gardens are, as one might expect, on quite another scale of magnificence, as here no expense is spared. Still, great outlay is by no means the only

FIG. 90.—ODONTOGLOSSUM CRISPUM LUCIANI.

masinia verticillaris, *Saussurea deltoidea* and *Russowii*, *Eubusba* species from Kagan, hardly in St. Petersburg!

Amongst shrubs, *Rhododendrons* stand in the front rank, and besides those incorporated in the catalogue, there are *R. brachycarpum*, *R. campanulatum*, *R. caucasicum*, *R. hirsutum*, *R. kantschaticum*, *R. lanatum*, *R. parvifolium*, *R. Przewalskii*, and *R. Ugerii*, as well as species *R. lapponicum*, *R. villosum*, *R. myrtifolium*, *R. intermedium*, *R. latifolium*, *R. Cunninghamii*, *R. Rosanumii*, *R. campylocarpum*. All of these are hardly at St. Petersburg. The following were likewise observed:—*Lonicera purpurascens*, *Daphne altaica*, *Spirea Hæquetii*, the charming *Philadelphus parviflorus*, *Andromeda Mariana*, *Larix nigra*, *Spirea Humboldtii*, *Lonicera sylvigantica*, *tangutica*, *nervosa*, *Regeliana*, *Rhamnus daburica*, *Ribes borejense*, the new Caucasian *Acer Trautvetteri*, &c.

PRIVATE GARDENS.

Among private gardening establishments, that of His Excellence, General Durnow, takes the first place.

thing needful in cultivating fine plants. Those which had the greatest interest for me were the Taurian garden and the garden at Felagin Ostrow; the former having to furnish the decorative plants for the Winter Palace, and the latter those for the Antischkow Palace.

Owing to the great size of Russian buildings, one can form no idea of the suitability or number of the plants grown for purposes of decoration.

The Winter Palace has a saloon called the Nicholas Saloon, which is decorated with seventy-two Palms of an average height of 8 to 10 yards! The Palm stand in six rows of twelve plants each; and a table surrounds each plant tub, at which ten persons can be comfortably seated at dinner. The crowns of these Palms do not touch each other, but stand so far apart that each can be seen to advantage. What is of interest to a gardener is that the extreme height and diameter of the tubs are only 75·6 cm. (30 inches), and the court gardener, Von Siessmeyer, is compelled on account of the tables, to keep to these dimensions.

The Palms remain in the palace from January to May, and in this interval they lose from seven to eight leaves, which must be replaced by an equal number of young ones before the following month of January. This piece of the gardener's art or conjuring trick, as we must call it, is carried out in this wise. When the plants come out of the palace they are turned out of the tubs, the roots severely shortened with an axe, and the ball re-tubbed in a mixture consisting of equal parts of heavy and light turfy loam, mixed with which are 10 to 11 litres of bone-meal, and the plants are then placed on a warm bed in the Palm-house. Here they throw out 7 to 8 new leaves by the new year, and are then transported, often with the thermometer at -20° Réaumur (-45° Fahr.), well packed in thick coverlets, to the Winter Palace.

The number of plants employed in decorations on great occasions amount to 17,000, and at small fes-

I have no intention of noticing all the different species of these plants, but only those which it is rare to see used in the dwelling. One of the most common is *Cissus antarctica*; and almost as common are *Jasminum Sambac* and *Sansouera guineensis*. Judging by the dimensions of the plants observed in the windows of houses inhabited by the lower classes of the population, these plants are great successses.

At the time of my visit—July—the *Jasminos* was literally covered with bloom. *Bromelias* are greatly admired, and a few amateurs possess large collections of them, likewise of Cactus. Specimens of *Pandanus utilis*, 6 feet in height, and perfectly healthy, and of *Cocos Weddelliana*, were remarked, the latter quite different in habit in old age from what it is when young.

A favourite Orchid, and one that does well in apartments, is *Stanhopea* in variety. Besides *Aralia reticulata*, it is not rare to find specimens of other ornamental species, as *A. Sieboldi* and *A. papyrifera*.

Weise an exceedingly intelligent manager of their public gardens and open spaces. These increase year by year, and at the present time the enormous area that lies between the Winter Palace and the old Admiralty buildings is being converted into an ornamental garden.

The carpet-bedding style still finds many admirers, but the preference for flowering plants of various kinds in place of variegated *Polargoniums*, and the usual carpet-bed plants, as *Irisine*, *Alternanthera*, *Pyrothrum*, &c., has begun to assert itself; and although the artificial and geometrical forms of the beds are retained, and the planting of large beds with one kind of plant is still carried out, the clipping and shearing of the plants are no longer the fashion, the various designs being filled with plants of varying height, and flowering subjects in greater variety. *U. Dummer*.

FORESTRY.

TYPES OF BRITISH WOODLAND. I

We have said that Oak woods have been modified by modern methods of management into variations from the original type. Although the result of these modifications has, in many cases, entirely obliterated the ancient order of forest scenery, yet, thanks to the planters of the last century, typical Oak woods are still plentiful enough in England. Unlike the Beech, however, the Oak tolerates the presence of many lowly forms of vegetation beneath its deep, but comparatively open crown, and it is only during the earliest stages that the leaf canopy can be kept sufficiently dense to kill surface-vegetation, and if not entirely suppressed over too large an area, it re-asserts itself. When Oak woods have been raised from a thick bed of acorns or plants, and left to fight it out from the start, a crop of fine timber is invariably the result on good soil and a favourable situation.

Uniformity rarely exists over a large area, it is true; but uniformity of soil and other conditions is equally rare, and with a long-lived species, slight differences in vigour or adaptability to the situation, which pass unnoticed in young trees, become more accentuated with age. With the exercise of every possible skill and care, the forester must still learn much in the Lands of Nature, and the number of really fine specimens of mature trees to be found upon a given area is usually small in comparison with small or badly shaped stems, and the poorer the soil, the more numerous the latter become. In most cases, too early and too severe thinnings have been carried out. An old proverb runs: "The Oak will stand bare-headed, but not bare-footed;" but this does not imply that the early training, in the shape of "drawing up," which is necessary in growing good timber of any kind, can be dispensed with in the case of the Oak. If we are not mistaken, the above-quoted proverb is of French origin, and in France a warmer climate renders the preservation of soil-moisture more imperative than with us. Hence the practice which prevails of under-planting middle-aged Oak-woods with Beech or Hornbeam, or of growing these species in combination. These methods of growing Oak might be more often followed on the lighter soils, especially in the south of England, and it is astonishing to find, on even poor sandy soils, Oaks of great length and respectable dimensions, which have been drawn up among Beech trees without artificial interference. Such timber, it is true, is usually of little value for many kinds of work, but is well adapted for cleaving, and several other estate purposes. On fairly dry soils, however, where Oaks of fair quality can be grown, the Beech requires to be kept in check before the Oaks have finished their growth in height, so that the crowns of the latter may develop to the utmost. On heavy soils Beech does not thrive so well, nor is the dense shade of the latter such a desirable condition and in such cases natural herbage usually forms the undergrowth.

The most frequent, and from the sportsman's point

FIG. 91.—*ODONTOGLOSSUM CRISPUM* LINDEL. (SEE P. 268.)

tivities from 8000 to 10,000. Moreover, this garden furnishes the Winter Palace with a portion of the flowering plants required, namely, 200 to 300 Camellias, 700 Narcissus, 1200 Tulips, 2500 Crocus, 5000 to 6000 Hyacinths, and 40,000 Lily of the Valley, which is about one-sixth of the entire requirements, the remaining five-sixths coming from Ellier's nursery.

The imperial gardens at Folegin Ostrow resemble the first-named, and together with the park is situated on an island in which nature and art are wonderfully blended. The following plants are regarded as being excellent decorative material, withstanding the inimical conditions of indoor culture better than most others, viz., *Aralia reticulata*, *Codiaeum* (*Croton*) *variegatum* var. *Corrieri*, *Cræva salicifolia* (probably saligna), the first two being first-rate plants for apartments.

PLANTS FOR DWELLING-ROOMS.

This reminds one of the plants used for the latter purpose, which I have remarked in St. Petersburg.

I observed several plants of *Cycas revoluta* in good condition. The layman may be surprised to learn that this species is cultivated by the Russian amateur, but the reason is to be found in the long-continued activity of the departed Regel. He was, although a German, the father of horticulture in Russia, which is a fact that cannot be denied.

PUBLIC PARKS.

Before I turn from gardening at St. Petersburg, I must say a few words about the public parks and gardens. The Russian has a great sympathy with Nature, and the vegetable kingdom plays a greater rôle with him, and stirs his feelings much more than is the case with the western European nations. This is made apparent in the immense numbers of the people who visit the numerous parks and gardens of the city. The municipality on its side has done much in tastefully decorating the large squares and "places," of which there is no lack in the more modern parts of the city, and they have got in Mr.

of view, the most desirable form of Oak wood is probably that in which Hazel fills up the space between the trees. This style of woodland varies a good deal as regards the proportion in which timber and underwood bear towards each other. In some cases we find the Hazel simply an undergrowth, and almost entirely shaded by the crowns of the trees; in others the trees are few and far between, and the Hazel coppice forms a goodly proportion of the crop on the ground. The more closely the latter case is approached, the shorter stemmed and more heavily branched do we find the timber. Many fine specimens of Oaks, containing much valuable timber, may be met with, it is true, which have not been subjected to any close struggle with their neighbours; but where such occur, we may safely conclude that soil and situation leave little to be desired, and that even better results might have been obtained with proper treatment. Two cases in point occur to us at this moment, both of which have their existence in two of our royal forests, one a wood of tall, clean, and massive boles, which has evidently been little, if at all, subjected to the process of thinning; the other, in which the trees stand like fruit trees in an orchard, with almost painful regularity, but the produce of which is yet, principally branches. One is characteristic of the sylvicultural, the other of the arboricultural, systems of managing the Oak. *J. C. Forbes.*

(*To be continued.*)

CULTURAL MEMORANDA.

TORЕНИЯ FOURNERI.

WELL-GROWN plants of *Torenia Fournieri* make a nice edging to a plant-stage in the greenhouse or conservatory, and are useful for mixing with other plants on flower-stands in apartments, &c. The seeds being small, should be sown in pans of light soil, and be slightly covered with fine mould and stood in a moderately warm house. The seedlings should be transplanted an inch apart, in pans filled with any moderately rich kind of gritty soil, and later on they may be potted, several together, in 4's, and stood in cold frames after the weather has got warm. *Torenia*s are liable to be infested with aphides, to destroy which the plant should be fumigated occasionally. The plants require to be freely supplied with water, and with manure-water when pot-bound.

FRANCOSA RAMOSA.

This pretty greenhouse plant may be raised from seed sown forthwith in pans of sandy soil, and stood in a temperature of 60°, and kept moist and shaded from the strong sun. If the seeds are new, germination will soon take place, and, when large enough to handle, the young plants should be pricked off into other pans, and later on potted into 60's, and grown in a house with a mild moist heat for a while, after which they should be afforded a slight shift and be placed in a cold frame. The plant is readily multiplied by division, taking the young side-growths shortly after the plants have flowered, potting them in 60's, and keeping them close in a cold frame placed on the north side of a wall. The leaves should be kept fresh by repeated light syringings. When well established report them into rich sandy loam and half-decayed leaves, or Mushroom-manure. If stood in a cold frame, not too close together, it winters well, even if light frost get to it. The stoutest of the plants which have flowered may be re-potted somewhat low down in the soil, so as to let side-growths make roots in the soil. *H. Maudslayi.*

THE WEEK'S WORK.

THE KITCHEN GARDEN.

By W. PAPE, Gardener, Highclere Castle, Newbury.

Carrots, Parsnips, &c.—As soon as the earliest crops of Carrots, Parsnips, &c. appear above ground, advantage should be taken of a dry day to rim the Dutch-hoe through the soil, between the rows, which will destroy small weeds, and otherwise benefit the crop by admitting air and sunshine. Thin the plants as soon as the first true leaf is formed to about 3 inches apart, and in a fortnight or three weeks the second and final thinning may be done; the Early Horn varieties sown for use as pulled being left at

6 inches, while those intended for storing should be allowed from 9 inches to a foot between each plant, the latter distance being necessary to grow good roots for exhibition. After each thinning, give a light dressing of fresh soot, and stir the soil with the Dutch-hoe. If Parsnips were sown in bunches, they should be thinned to a couple in each patch as soon as the plants are seen, and further reduced to one at a late date, to guard against any blights. These may be successfully transplanted, if moved with care during showery weather. It is not yet too late to sow seed, if by any chance it may have been neglected earlier; the smaller roots resulting from late sowings are sometimes more appreciated than large produce.

Planting-out Onions for Exhibition.—Onions sown early in the year, and pricked out in boxes, if properly hardened off, are now ready for planting out. Assuming that a plot of ground has been previously prepared by liberal dressings of manure and deep cultivation, it should now be made thoroughly firm by treading whilst sufficiently dry on the surface to prevent the soil sticking to the feet. Then plant in rows 15 to 18 inches asunder, and place the Onions at about 15 inches apart in the rows. Planting may be done with a trowel, or dibble, as preferred, but care must be taken to plant firmly, and just deep enough in the soil to keep the plant upright. It is advisable to select showery weather for this work if possible, but should it be dry at the time, water should be given separately to each plant with a spout-can as each row is finished, and afterwards run the Dutch-hoe lightly through between the rows.

Celery.—Trenches may be prepared at the first opportunity for the earliest batch of Celery, and ground that has recently been occupied by Brussels Sprouts, Broccoli, or similar green crop is very suitable for this purpose. I prefer trenches wide enough to take two or three rows of plants as being economical in space and labour, the produce being in no respect inferior to that grown in single trenches. Those to contain two rows of plants should be made 2 feet wide and 12 inches in depth when ready for the manure, which should be put in after breaking up the subsoil deeply at the bottom of the trench; procure some well-rotted cow-manure if possible, and after putting in a good depth of this material, return enough of the good surface-soil to plant in. Three feet in the clear should be allowed between the trenches, or 5 feet measuring from centre to centre. These ridges between the Celery can be utilised for planting-out early Lettuce, dwarf Beans, &c. which will be out of the way before the soil is needed for earthing-up the crop. When the trenches are ready and the plants are properly hardened, lift each plant with the trowel, and plant with a good ball of earth attached, watering thoroughly immediately after. Continue to prick-off successional batches in boxes or frames as soon as ready, and supply them at all times with an abundance of water.

THE FLOWER GARDEN.

By CHARLES HERRING, Gardener, Dropmore, Maidenhead.

Antennaria furnish useful plants for filling beds, and flowers for cutting in the early spring. Seeds may now be sown of that pretty-looking variety, *A. coronaria*, for supplying flowering plants next year. A coronaria seed-beds or patches should be prepared where the plants are to remain and flower—that is, without transplanting; therefore the ground should be in a fairly good condition, and well tilled, the seeds being sown thinly in drills drawn about 9 inches apart. The seeds can be the more evenly and readily distributed if they are first rubbed and mixed in partially-dry sand.

Sunflowers. Perennial species may still be increased if necessary by division. Where pieces are cut away from established clumps, the ground should be made quite firm around the remaining portion, and if possible some new and rich soil be worked in around the roots. All the varieties of the *Helianthus multiflorus* section divide safely now, as do also *Helianthus* and *Kuhbeckia*, which are nearly allied to the former. Some of the annual Sunflowers are also desirable subjects, both the tall double and the single flowered, as well as the dwarfier growing miniature varieties, the last named being useful for filling odd corners in herbaceous borders, and for use as cut flowers. The seeds should be sown in large-sized 60-pots, two or three in each, thinning the seedlings to one—the strongest of the tall growing varieties, or three of the dwarfier miniature varieties. Till germination takes place, the pots may stand in a

mild hot-bed frame, and the plants gradually hardened off and planted out without further trouble being taken. When planting, scatter a little soot around them to prevent injury by slugs.

Various Operations.—Sowings of Sweet Peas, Mignonette, and other annuals, for affording cut-flowers, should be made at intervals of a fortnight or thereabouts during the next six weeks. The pricking-out of seedling Pentstemons, Antirrhinums, *Fetuinia Verbenas*, and other similar subjects, should receive early attention, as if allowed to become spindly in the seed-boxes, &c., they seldom attain to the vigour of those that are duly attended to in this respect. Mild hot-beds, on which a frame can be placed, with a bed of about 4 inches in depth of soil, for receiving the seedlings, form the best and simplest means of dealing with large numbers of seedling bedding plants at this season. The lights should be kept close, and the seedlings shaded for a few days from bright sun, gradually admitting more air and light when they are becoming established; eventually thoroughly hardening off preparatory to planting out by the entire removal of the lights, excepting during periods of cold weather.

*Bedding *Platycodon*.*—These, if well established, should, as far as convenience affords, be removed to cold pits and frames, or, if coming from houses with a cool greenhouse temperature, may go under a frame-work of trellising and be covered at night, or when otherwise cold, with mats or canvas. If removed from a warm and moist temperature, they should be kept close in frames or pits for a few days, that is, until inured to the change, and be shaded slightly during bright sunshine, otherwise the foliage may get discoloured. The propagation of various subjects should continue briskly now, until the stock of plants is sufficient for the various purposes intended. *Heliotropes*, *Ageratum*, *Nasturtium*, *Coleus*, and such like, strike readily at this season, if dibbled into boxes of light soil and stood in any close, warm house. *Heliotropes* transplant badly, and should, when struck, be potted up simply into small pots, and from these they may be eventually turned out into the beds without much risk of a check. Where *Alternantheras* are used for supplying a groundwork for carpet or other bedding arrangements, frames on hot-beds afford the readiest means of increase, where cuttings may be dibbled in thickly; and when struck they can be hardened off and set from the hot-beds direct to the beds early in June. Seedling *Hollyhocks*, now standing in 60-sized pots, may, if well-rooted, be shifted into large 4's, in which they will make strong plants for turning out into the borders in a few weeks' time. Subtropical bedders must not be allowed to become pot-bound and stunted, but be shifted and kept in an active growing state.

All arrears of work in the pleasure-grounds should be pushed on as fast as weather and circumstances permit; the unfavourable character of the season has for some time hindered all outdoor work. The re-laying of Box edgings should now be brought to a close. The cutting the turf verges of walks with the edging-iron should be done where the edges are irregular. The proper width of walks whose edges are pruned away in this manner is restored by cutting a strip of the turf on each side 1 foot wide, and pushing it towards the walk, and making it firm, the interval between the removed and the unreworked turf being made good with fresh turf. The tidiness of the lawn should be maintained by mowing and sweeping as often as becomes necessary.

PLANTS UNDER GLASS.

By G. H. MARCOCK, Gardener, Luton Hoop Park, Luton.

Winter-pancrying Carnations.—The young plants will probably stand in need of a shift into larger p-t's, and before a beginning is made in the potting, they should be cleansed from green-fly and red-spider. If the plants are to flower in 5-inch pots, the potting-compost should be the same as that I have previously given, with the addition of a small quantity of fresh soot, which should be well incorporated with other ingredients. Let the plants be but little disturbed in turning them out of their pots, and pot them with a moderate degree of firmness—not, however, using a hammer, and leave ample space for admitting water. The re-potted plants may be placed in a span pit or frame near to the roof-glass, affording a temperature of about 55° by night, 65° or more by day, with ample ventilation after the first week, lightly dewing them over with the syringe in warm, sunny weather. These plants will require to have the points pinched out twice or oftener during the early part of the growing-season. Plants of *Carnations* which are of 1896 and 1895, should be examined, the healthiest

being selected to be slightly reduced in the size of the balls, and potted in 7 and 8-inch pots. The flowers from these older plants will not be so large as those furnished by the plants of the present year's striking; but for supplying flowers in the months of November and December, they will be much more valuable. At this season these plants should be kept in a greenhouse or cold-frame, and somewhat warm and close for the first fortnight after re-potting.

Souvenir de la Malmaison Carnations.—Any plants which may be showing their flower-spikes should be kept quite free from green-fly, and a little drier at the roots, it being advisable to rather err in that direction than to keep the soil wet. Let staking and tying receive proper attention, and tie loosely, in order that the ties may be readily moved up the stake with the advancing growth of the spikes. When affording stakes, use no more than are actually needed, and in all cases let these be as thin as is consistent with the purpose they are meant for; and I would suggest the use of the lateral growths of Bamboo canes, these being thin, light, and durable.

Plumbago rosea.—Cuttings may now be taken from old plants that were pruned hard back after flowering. After preparing them, place four round the sides of a 3-inch pot, and plunge in a bed in the propagating-pit, keeping them moist and shaded, and in about three weeks the cuttings will be ready to pot singly in 60's. When the roots reach the sides of the pots, shift into pots one size larger, the following shift being into 32's, in which they may be allowed to flower. A good mixture for the last re-potting consists of three-quarters good fibry loam, one quarter leaf-mould, and a good proportion of sand. In the early stages of growth, *Plumbago rosea* requires stove temperature, but in summer a frame in a sunny spot is more suitable. The plant should be stopped when in the first pot, and once again after it is established in the flowering-pot. For brightening the stove during the winter months, and for general effect it is a really excellent plant, and being graceful in habit it affords a pleasing contrast with others.

Cleodendron fallax.—Seeds of this plant should now be sown in seed-pans, and in a mixture of leaf-mould and sharp sand, sowing evenly over the surface and covering lightly. When the seedlings can be readily handled prick them off in very small pots and keep them in heat, and when established at rootings freely lift them into 5-inch pots, using a compost of peat half, loam quarter, and plenty of sharp sand. During the summer this species may be kept in the intermediate-house, in a position near the glass, and where they can be reached with the syringe, red-spider being very liable to injure them if the surroundings are dry, and these mites soon disfigure the foliage. Plants so treated flower when about one foot high.

THE HARDY FRUIT GARDEN.

By H. W. WARD, Rayleigh, Essex.

Fruit-tree Stocks.—Remove all growths that push below the grafts upon fruit-tree stocks as soon as they appear, so as the sooner to effect a complete union of stock and scion. Should the clay have fallen from any grafts which are not yet sufficiently united to the stocks to enable them to bear exposure to light and air without injury, it should be replaced by clay which has been worked to the consistency of putty, making it full in the centre, and tapering off to the wood a little above and below the point where the scion is placed. In the case of fruit-tree stocks, as well as engrafted stocks, growing in light, shallow soil, it will be advisable to give them a good watering at the roots, and apply a coating of short manure or leaf-mould (where the latter is plentiful) between the rows to the depth of 2 or 3 inches.

Raspberries and Strawberries growing in light or shallow ground may be considerably benefited by watering them at the roots at short intervals during dry weather. It is absolutely necessary to keep the soil uniformly moist about the roots of all kinds of fruit trees and plants during the period of active growth, if remunerative crops are to be secured. The beds, too, must be kept free from weeds.

Miscellaneous Work.—This will consist in the thinning out and pinching of young growths, tying in and securing young shoots by position by means of nails and shreds, keeping the same free from the attacks of aphid, &c. Run the Dutch-bee between lines of Gooseberry and Currant cuttings, as much with a view to aerate the soil as destroying seedling weeds. If not already done, hush-barrow and roll grass in orchards which had been top-dressed some

time ago, and in which the space allowed between the trees will admit of the work being done without injury to the stems of the trees.

THE ORCHID HOUSES.

By W. H. WITTE, Orchid Grower, Barford, Dorking.

Peristrophe.—The Dove Orchid, *P. elata*, *P. Lindenii*, *P. pendula*, and *P. aspera*, are plants which require a long rest in the winter, and plants of these species will at this date be pushing up growths from the base of the pseudo-bulbs, and in need therefore of some new material about the roots. Healthy plants, and those which have sufficient space for growth, need not be disturbed, but have the worst-out material picked out, and fresh substituted for them. The plants that are in need of more rooting space should be turned out of their pots and placed in others large enough to allow for two or three seasons' growth. Crocks should occupy the pots to one-half their depth, and the compost be made up with two-thirds hard turfy loam, one-third fibrous peat, with the addition of some dried cow-dung or Oak-leaf soil. The soil must be filled in firmly around the roots, and up to within a space of 1 inch below the rim of the pot. When the new roots are noticed at the base of the young growths, let the surface of the soil be covered with living sphagnum-moss. After re-potting the plants, they will not require much root moisture; but plants in vigorous growth should be liberally supplied with water, and as soon as the new pseudo-bulbs begin to form, alternate applications of weak liquid manure will benefit the plants. *Peristrophe* are at home in warm, moist stoves, or the East Indian-house, and during the earlier stages of growth they require to be shaded from sunshine; but as the pseudo-bulbs approach maturity, gradual exposure to full sunshine should take place.

Angulosa.—The species *A. Clowesii*, *A. eburnea*, *A. uniflora*, and *A. Buckeri*, now sending up their flower-spikes and young growths, should be stood on a level of soil in the intermediate-house, and afforded water in sufficient quantity to moisten the compost. It is not advisable to disturb these species by re-potting them before the flower-spikes are out, at which time roots emerge from the new growths. Avoid letting water lodge in the centre of the breaks, these being very liable to damp off in consequence.

Calogyne cristata and its varieties *maxima*, "Chatsworth," *Sanderi*, *Lemouiana*, and the pure white variety *hololeuca*, are valued decorative plants, and useful for supplying flowers during the winter. Any specimen which have reached an inconveniently large size may now be divided and re-potted. If plants of moderate size are to be grown into large specimens the present is the best time to re-pot them. Such plants ought not to be disturbed at the roots, or considerable time will elapse before they are brought to their former condition. Being plants of easy culture, it matters little whether they are grown in pots, pans, or baskets, but whichever is selected should be well drained. As a potting mixture, rough, turfy loam and fibrous peat in equal parts, with an addition of sphagnum-moss and a few thick pieces of crocks to assist drainage, may be employed. Place the plants in the coolest part of the Cattleya-house, or where an intermediate temperature is maintained. Generally, after disturbance of the roots, the pseudo-bulbs shrivel slightly, still it is not good practice to deluge the plants with water to preserve their plumpness, because an over-abundance of water at this period might cause the older roots to decay, and the pseudo-bulbs to shrivel still more. Rather give them an occasional overhead syringe, and keep the atmosphere around them moist; and till some degree of progress is made, shade them from sunshine. Established plants require abundance of water till such time as the new pseudo-bulbs are fully made up. Other species which grow well in an intermediate-temperature, as *Calogyne conferta*, *C. elata*, *C. Rossiana*, *C. corrugata*, *C. barbata*, *C. speciosa*, *C. ocellata*, *C. graminifolia*, *C. Thuniana*, *C. odoratissima*, and *C. corymbosa*, which are now making new growth, may be re-potted. *C. fasciata* produces pseudo-bulbs racemes, and basket-cuttings best for it. The warmest are *C. Massangeana* and *C. tomentosa* should also be grown in baskets, suspending them, while growing to the roof, on the shady side of the East Indian-house, and when at rest, hanging them in the intermediate-house. *C. Dayana* and *C. ochracea*, now showing their flower-spikes, will require more water at the root. The rare *C. Sanderiana*, a plant that is at rest in the spring, should be placed in a light

position in the cool-house, and kept rather dry at the root, till the flower-spikes appear, when the plant should be steeped in tepid rain-water, and returned to its former position in the Cattleya-house. *C. asperata* Lowi requires stove treatment; it is also beginning to grow, but should not be re-potted till the flowers have faded. All of the species named root freely in ordinary Orchid-compost. *C. fulgens* is a distinct growing species, its habit of growth being erect. To meet its requirements in this respect, the plant may be fastened to upright Teak-rafts, the roots of which are about an inch apart. Insert the lower part of the raft into a pot, fixing it with crocks, over which place some peat, and prick in heads of sphagnum-moss thickly over the surface, as the plant delights in aerial moisture.

FRUITS UNDER GLASS.

By F. HARRIS, GARDENER, EASTON CASTLE, LEICESTER.

The Early Fig-house.—If the first crop of fruit has been gathered from the trees, syringing may be discontinued, and a copious application of water should be given the roots, in order that the second crop of fruits may experience no check. Remove all weak growths, and in the case of trees planted in the border, and trained on trellises, the shoots may be tied down a little, but do not tie them severely. If the points do not touch the glass, let them turn up toward the sun, as this strengthens and ripens them for the production of next year's fruit. Figs trees usually produce a large number of fruits for the second crop, and any thinning that is done will tend to increase the size of the fruits that are left. On each tree when the fruit is ripening, syringing should be withheld and a dryer atmosphere maintained still. The fruits should be left upon the trees till thoroughly ripe, or the flavour will be deficient. Figs require careful packing, but given this, they will travel very well. We pack hundreds annually, and adopt the following system:—As the fruits are gathered perfectly ripe, they are placed carefully in shallow trays lined with wadding and tissue-paper, taking care that the fruits do not touch each other. When nicely cooled, we wrap them first in soft Vine leaves, then in white tissue-paper, and pack firmly in a close layer, either in soft, well-beaten moss, which we always use here, or in fine wood-wool.

Succession-houses.—Trees upon which the fruit is starting to swell the second time will need liberal supplies of water, and if they are carrying good crops, liquid manure should be given. Syringing them frequently until the fruits commence to ripen, and if it is desired to hurry the fruits a little, this may be done by closing the house, with plenty of sun-heat, and a corresponding degree of moisture.

Lute-houses.—Those started at the date suggested in a previous Calendar will now have developed their fruits sufficiently to admit of them being thinned, and it should be done as soon as possible. Many gardeners do not thin their Figs, but we find it advantageous to thin the fruits to three, two, or one upon a shoot, according to the distribution of the crop and the size of fruits required.

Melons.—Upon very early plants the fruits will now be swelling fast, and plenty of food and moisture at the roots, especially if the plants be in pots, should be afforded. Weak liquid manure may be given alternately with clear water, taking care that it is not greatly below the temperature of the atmosphere of the pit or house. Where canker is apprehended, care must be taken not to wet the stems when watering; and should the slightest sign of it appear, it may be checked if dusted at once with a little fine quicklime. As the fruits show signs of ripening, water must be given more sparingly, or cracking of the fruit will be the result, especially of such thin-skinned but finely-flavoured varieties as *Victory of Bath* and *Easton Castle*. Keep all lateral growths closely pinched at this stage, so that the strength of the plant be not wasted. Plants upon which the fruits have just set should be relieved of all those beyond the number it is intended they should carry. If medium-sized fruits are desired, each plant may carry four. We generally plant ours close together, run them up on a single stem, and let each plant carry two. This is a simple system, and generally two fruits will swell together while sometimes it is difficult to get four or six to do so. Keep all side-growths pinched out of succession plants till they reach the trellis, then leave one growth to each wire. Sow a few seeds occasionally, to keep up the supply.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY,	APRIL 24	Royal Botanic Society, Meeting.
TUESDAY,	APRIL 27	Royal Horticultural Society's Committees; Lecture on "Winter and Spring Bedding."
FRIDAY,	APRIL 30	Annual Dinner of the Royal Gardeners' Orphan Fund at Hotel Cecil.

SALES.

MONDAY,	APRIL 26	Important Sale of Begonias, Carnations, Dahlias, &c., at Protheroe & Morris' Rooms.
TUE-DAY,	APRIL 27	Imported and Established Orchids, at Protheroe & Morris' Rooms.
WEDNESDAY,	APRIL 28	Japanese Lilies, Carnations, Gladioli, Begonias, &c., at Protheroe & Morris' Rooms. Palms and Ornamental Plants from English and Foreign Growers, Border Plants, Bulbs, Lilies, Roses, Shrubs, &c., at Stevens' Rooms.
THURSDAY,	APRIL 29	Special Sale of Orchids in Flower and Bud, Importations of Orchids, &c., at Stevens' Rooms.
FRIDAY,	APRIL 30	Imported and Established Orchids, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—50 1°.

ACTUAL TEMPERATURES.

LONDON.—April: Max., 55°; Min., 46°.

PROVINGES.—April 21 (6 P.M.): Max., 57°, Valencia; Min., 42°, Aberdeen.

Of late years much stress has been laid on the difference between the vegetative and the sexual conditions of a plant, which are even asserted to constitute distinct "generations." Very often the plant, in its sexual or reproductive state, does differ very greatly in appearance from the plant in its vegetative or neutral stage. Nevertheless, quite as great differences occur sometimes in the different phases through which the plant in its purely vegetative state passes, as witness the illustration, fig. 92, showing the primordial scattered leaves of *Pinus Parryana*, as well as the adult foliage on short spurs. The *Retinosporas* afford similar illustrations; and we know that that particular phase of vegetation can be perpetuated by cuttings, and remain in the same condition for an indefinite time. One of the most striking illustrations of alternation is afforded in the reproduction of Ferns. The spores do not immediately reproduce the plant, but they fall off, as many buds do, and, under propitious circumstances, they develop a flat, green plate (the prothallus), on which are formed the "antheridia" and the "archegonia," bodies corresponding respectively to the anthers and to the ovaries of flowering plants. It is customary to consider the frond of a Fern, with its spores, as belonging to one generation; the prothallus, with its two kinds of sexual organs, as representing another generation—the frond being called the "sporophore," the prothallus the "oophore." Without either the existence of the plant would be incomplete; but of the two, the vegetative or sporophore phase is obviously the more essential.

FIG. 92.—*PINUS PARRYANA*.
Showing scattered primordial leaves and tufted permanent leaves.

FIG. 93.—*FUCUS MACROPHYLLA*. (SEE P. 273.)
(Showing small bulbs intermixed with ripe capsules.)

FIG. 91.—*SOLANDRA GRANDIFLORA*: FLOWERS CREAMY-WHITE. (SEE P. 273.)

Now, what is there in this arrangement to suggest anything more than a different phase of growth, a stage in the progressive sequence of events from birth to death? Nothing externally, as far as we can see, but the fact that the oophore sometimes, but by no means always, becomes detached from the sporophore and leads an independent life. The oophore or prothallus corresponds roughly to the "inflorescence" of flowering plants in that it bears the flowers or their representatives. The inflorescence does not usually separate itself from the parent axis or sporophore, although sometimes it does so, as in the case of the male catkins of dioecious or monoecious plants, Willows, Hazels, &c. Again, in the flowers the microspores or pollen-grains are detached from the parent plant as freely as either the spores or the atherozoids of a Fern can be. The megasporange (ovule) and "megaspore" (embryo sac) do not separate themselves from the parent stock. Hence, if detachment be considered the sign of an alternation of generations, we have the anomaly that the male part of the plant constitutes a generation, whilst the female part does not. The fertilised embryo is in any case a new individual.

In connection with this so-called alternation of generations the phenomena of budding have to be considered. Vegetative buds may occur on almost any part of the plant. They are very common in Ferns, and some of the phenomena recorded under the head of Apogamy, where a bud is formed on the prothallus, and Apospory, where the prothallus is formed without the mediation of a spore, seem to be referable simply to the production of buds, or parts homologous to buds. Dr. STANSFIELD even records the co-existence of the neutral, of the aposporic, and of the apogamic conditions, a fringe of prothalli being formed on the fronds, and the prothalli budding out into fronds; and on p. 276, Mr. DRURY records a Fern which shows on the same frond both the aposporous and the apogamic condition. Mr. LANG has also noted the presence of sporangia or spore-cases on the prothallus of a Scopolopendium. To which generation, we ask, can an organ be assigned which bears at one time nothing, at another sexual organs, at another buds, and at another spore-cases?

The production of buds in place of flowers is strongly exemplified in the case of *Furcraea*, where the "inflorescence" usually produces hundreds of bulblets and no flowers. We suppose no one would consider these separable buds as constituting a distinct generation. Since beginning this article, specimens gathered by Dr. MORIS have reached us through Mr. WATSON, which bear ripe seed-vessels and buds on one and the same inflorescence (fig. 93). It is hard to conceive of a difference of "generation" in this case.

The question to be decided is, whether the observed phenomena are to be taken as indicative of new and distinct "generations," or of different stages of growth of the same generation.

The point is one of much importance, because some go so far as to deny any homology between the organs belonging to the one generation, and those pertaining to the other; and students are warned against applying inferences drawn from the one to the other set of organs. The reader will find these subjects clearly treated by Mr. DRURY in his paper on "Fern-generation" published in the last number of the *Journal of the Royal Horticultural Society*.

A remarkable difference has, it must be added, been pointed out in the nuclei of the vegetative and of the reproductive cells respectively. The nucleus of the cell, as is now known, breaks up into a number of separate elements, called "chromosomes;" and the number of these chromosomes in the reproductive cells is only half as large as that in the vegetative cells; so that, from this point of view, the distinction between the two generations is well marked in the Gymnosperms as well as in many of the Cryptogams. In the thallus of the Liverworts, which corresponds to the prothallus of Ferns, Professor FARMER has ascertained that the nuclei show a reduction in the number of chromosomes, two chromosomes being, as it is believed, fused into one. Thus, the two generations of "sporophyte" and "gametophyte" are, it would seem, really characterised by a difference in their nuclear constitution. The developments and consequences of these phenomena are very complicated and very far reaching. Even the cause of the formation of "sports" may possibly be traceable to nuclear changes of the kind mentioned. There is obviously need of much further investigation; but the number of investigators in a subject demanding so much minute research and patient skill must necessarily be few, and the time involved in obtaining results must be long.

The whole subject has lately been ably discussed by Sir EDWARD FRY, in a recent contribution to *Nature*, to which we would draw the attention of our readers.

SOLANDRA GRANDIFLORA.—This fine climbing plant, now rarely seen in gardens, is indigenous to Jamaica, where it goes under the name of the Peach-blossomed Trumpet-flower. Under cultivation the flower is white, with a purple tinge on the interior of the tube, but under the intense light of the tropics it is of a pale flesh colour. It first flowered in this country at the Royal Gardens, Kew, in 1818, the figure given in the *Bot. Mag.* of that year having been taken from a flower furnished by Mr. ALTON. It also flowered in Mr. SALSBURY's garden at Mill Hill, at about that time, and produced fruits there. The genus was named in honour of Dr. Solander, a pupil of Linnæus, and fellow traveller of Sir Joseph Banks in his voyage to the South Seas. Cuttings of ripe wood strike readily in heat; and the cultivation of the plant is not difficult, provided a well-drained fairly roomy border, and plenty of head-room are given it in the stove. We are indebted to Mr. G. BOLAS, gardener at Hopton Hall, Derbyshire, for the flower from which our engraving (fig. 94) is taken, and the following particulars:—"The plant is of interest from the time the buds begin to expand. The change in the colour of the flower is very remarkable, these turning from a pale olive green tinted with yellow, to a creamy white on the fourth day. I received the plant in the summer of 1896, looking like a dried stick, with no signs of life in it, it having travelled, wrapped in a newspaper, from the Island of Madeira. The plant had been stuck into the ground some days in a garden near Shrewsbury before I got it, and this gave me a hint as to the kind of treatment necessary to flower it."

ROYAL HORTICULTURAL SOCIETY.—The next fruit and floral meeting of the Royal Horticultural Society will be held on Tuesday, April 27, in the Drill Hall, James Street, Victoria Street, Westminster, from 1 to 5 P.M. A lecture on "Winter and Spring Bedding" will be given by Mr. A. DEAN, at 3 o'clock.

"THE JOURNAL OF THE ROYAL HORTICULTURAL SOCIETY."—The lately issued number contains Mr. DRURY's valuable paper on "Fern Generation;" Mr. JANNON's article on forcing Lilies of the Valley, wherein he tells us there are many thousand acres on the Continent and

in England devoted solely to the production of Lily of the Valley crowns. Mr. BURRILL follows with papers on the Gladiolus and on Hardy Summer Flowers. Mr. LEE'S discourses on the Chrysanthemum. Some valuable facts are brought to light in Mr. ROBERT FIFE's paper on Seed-growing.

HORTICULTURAL CLUB.—The monthly dinner and conversation of the club took place on Tuesday evening, 18th inst., when there was a good attendance of members and friends. Mr. HARRY J. VERRIN, Vice-chairman of the club, presided; and there were present Messrs. H. J. Pearson, Francis T. Rivers, H. Rivers, J. A. Cockett, J. Cockett, jun., H. Selfe-Leonard, James Walker, George Paul, C. E. Shea, J. Asbee, Dr. Ernest D'Ombraïn, H. A. A. D'Ombraïn, Philip Crowley, and the Secretary. A very interesting paper on "The Flower Gardens of Victoria," was read by Dr. Ernest D'Ombraïn, of Melbourne, in which he showed how erroneous were the opinions often entertained in this country as to the soil and climate of Victoria; he also gave an account of plants and flowers which best flourished in the colony. An interesting discussion followed the reading of the paper, and many questions were asked on some of the points elicited by the lecturer, to whom, on the motion of Mr. Veitch, a cordial vote of thanks was given. Thanks were also given to Mr. George Mount for some Canterbury Roses which he sent to decorate the table.

NEW YORK BOTANICAL GARDEN.—A second *Bulletin* of the New York Botanical Garden gives, says the *Botanical Gazette*, additional information as to plans. The many problems that have presented themselves for solution are discussed. The museum building, with a frontage of 304 feet, with two equal lateral wings, whose total completed length will be about 200 feet, will give ample space for collections and laboratories. The allotment of the grounds is of interest: buildings, with decorative approaches and surroundings, about 25 acres; Pines and other coniferous trees (90 to 100 species), 30 acres; deciduous trees (about 275 species), 70 acres; natural forest, mostly undisturbed, 65 acres; shrubs and small trees, 15 acres; herbaceous grounds for scientific arrangement, 8 acres; bog garden, 5 acres; lakes and ponds (exclusive of the Bronx), 6 acres; meadows, 10 acres; besides various provisions for aquatics, Vines, rockeries, &c. The *Bulletin* also contains Dr. BRITTON's address on "Botanical Gardens."

RADIOGRAPHY AND BOTANY.—Dr. HENRI VAN HEERCK, Director of the Antwerp Botanic Garden, has taken a series of fine photographs of flowers and fruits, especially of the flower of *Pavonia Makoyana*, the fruits of *Pisum sativum*, *Tamarindus indica* (the position of the embryo is shown remarkably clearly), *Papaver somniferum* (the walls and seeds being very distinct). Those interested in radiography (X-rays) may like to hear of a work which Dr. VAN HEERCK has written and illustrated with fine plates, entitled "Rayons X." It is the history of what has so far been done in connection with Dr. ROSEN's discovery. *Ch. De B.* [The first illustrations of the application of the X-rays to botanical purposes was given in the *Gardener's Chronicle*, Oct. 24, 1896, p. 491. Ed.]

A NEW USE FOR CYCAS REVOLUTA.—How ever interesting the Cycadæ may be from a botanical or paleontological point of view, they are not generally regarded as an important economic group; the only value, indeed, hitherto attributed to them has been for the sake of the starch which is found in the seeds of some and in the stems of others. *Cycas circinalis*, for instance, furnishes in India a quantity of starch, commonly known as sago, and used as food. From the stems of the Australian *Macrozamia* and the West Indian *Zamia*, starch is also obtained in abundance, as also from the plant to which we desire to draw attention, namely, *Cycas revoluta*, a Japanese species, where it is largely used as an article of food. The most recent development of this plant, however, from an economic point of view, is the utilisation of the fronds for plaiting into baskets and flower-pot covers. It would seem,

judging from the quantities of these articles now seen in shop windows, that this manufacture must be a large one in Japan, considering that waste-paper baskets made from these elegant fronds can now be bought for a few pence each; and the fronds themselves, simply dried, are also sold at about 2s. each for decorative purposes. The adaptive resources of the Japanese are truly wonderful. The old name of Sago-Palms, under which the plants were at one time known, is given to the baskets and fronds now on sale in this country.

CINERARIA BOULE DE NEIGE.—Messrs. LETELLIER ET FILS, of Caen, recently sent for our inspection a plant of a pure white Cineraria of good habit. The flowers were of moderate size and good substance; both rays and disc white. The plant was intended to have been exhibited at the Royal Horticultural Society, but it was too travel-stained to justify its appearance before the critics. It will probably be used as a decorative or market plant.

BOTANICAL EXPLORATIONS SIXTY YEARS AGO.—How much now well-known ground was, sixty years ago *terra incognita*, needs no telling here, but it is interesting to learn that in 1836, HARTWEG, the traveller for the Horticultural Society of London, first started for Mexico, Guatemala, and tropical America in general. There is an interesting account of this explorer's travels in *Erythraea* for March, wherein our readers who know not, or who have forgotten the details, will learn how many plants with which they are now familiar owe their introduction into America and England to this hardy and intrepid pioneer. The account is to be continued in the April number of *Erythraea*—a magazine in which, by-the-by, various other interesting articles and paragraphs are always to be looked for.

TASMANIAN APPLES.—The officials of the P. & O. Co. inform us that they have had telegraphic notice from Melbourne of the following shipments of fruits, &c., viz., per Orient Co.'s ss. *Austral*, 24,000 boxes; per P. & O. Co.'s *Paramatta*, 25,000 boxes of Apples—due in this country about May 19.

PRIZES AT THE HAMBURGH EXHIBITION.—This exhibition, which promises to be the most important horticultural event of the year, has, as is well known, received great support from the Emperor and many of the German Princes and Governments, and a number of citizens of Hamburg have instituted numerous honorary prizes, so that the more important exhibitors will receive, besides medals, more than 100,000 marks in money. Further, the Senate and the Municipality of Hamburg propose to offer 50,000 marks to the committee in honorary prizes and State Medals, a proposition that is sure to be approved and accepted. In view of the high value of the prizes, the desire to compete on the part of natives and foreigners has become so great, that fears are entertained that all of the entries cannot be accepted from mere lack of accommodation.

A CRYSTAL PALACE VICTORIAN ERA FLOWER SHOW is to be held on Wednesday and Thursday, June 23 and 24. The schedule we have just received describes the forthcoming show as "an exhibition of the more prominent plants and flowers introduced to this country since HER MAJESTY'S accession to the throne in 1837." There are only twenty-five classes, but some of these will occupy a considerable amount of space, and at the same time introduce features of some novelty into a present-day English flower-show. Class 8, for instance, is for a group of Conifers arranged in a space not exceeding 500 square feet, for which a 1st prize of £20 is offered. A group of Palms, to be arranged upon a similar space by nurserymen, should also make an unusual display. Classes for Begonias, Caladiums, Cannas, Colicueus, Ferns, Fine-foliage plants, Gloxinias, Hardy Alpine plants and Herbaceous plants, Orchids, Pelargoniums, Roses, and the inevitable group of Miscellaneous plants arranged for effect, have been provided, and the collections required of many of these are large. Finally, there is to be a miscellaneous group of plants introduced during HER MAJESTY'S reign, arranged in a semicircular space not exceeding 500

square feet. As the exhibition is to be opened upon the day succeeding the general commemorative festivities, it is likely to obtain a very large number of spectators.

FRUIT PRESERVATION.—An interesting experiment in the preservation of fruit by means of cold storage has been carried out during the past season by the Technical Education Committee of the Kent County Council at Dartford. The experiment has been personally superintended by two members of the committee, Messrs. HESKETH and CHAMBERS, whose reports are now issued. They state that the stores were kept at steady temperatures of 30° and 40° until near the end of the year, when it was considered there would be no further utility in prolonging the experiment under the same conditions. Mr. HESKETH'S report thus proceeds:—The fruit loses weight somewhat during the refrigerating process, as is evident by the amount of moisture collected on the brine walls, which amounts to 1.5 per cent. of the weight of the fruit per week. This moisture is absorbed from the fruits by the air during its natural circulation in the chamber, and deposited on the colder surface of the brine walls from which it is drained away. The air is thus kept in a dry condition. An object in future experiments will be to reduce this desiccation of the fruit, but still maintain the dry condition of the air, which is so essential in avoiding mildew. It is, of course, a matter of common knowledge that fruit, especially of the harder kinds, can be kept back for a time from ripening by means of refrigeration, such knowledge being taken advantage of for bringing fruit from Australia and the Cape to England; but one main object in this experiment was to show the cost of fruit preservation on a small scale, such as our fruit-growers might find of service. A careful log has, therefore, been kept of the working expenses, and this shows that the total cost of engine-power (gas at 3s. 6d. per 1000 cubic feet being used in a gas-engine) and all stores amounted to ss. 9d. per day. This does not include anything for labour, as only the occasional attention of a labourer otherwise employed is required. The cost of working by an oil-engine would be approximately the same. As mentioned in the first report, the refrigerating machine, which is the smallest size practicable, was capable of dealing with a much larger chamber, its average hours of working per day being only three-and-a-half. If an average of twelve hours a day for the working of the machine is taken, it could then maintain a store 24 feet by 24 feet by 8 feet high, which would be capable of storing some 2000 bushels of Apples. The cost of working the machine on such a chamber, based on the experience gained in the recent experiment, would be 2s. 2d. per day. Of course, larger installations, worked with larger machines, would cost much less to work in proportion to the quantity of fruit kept. It is proposed to make experiments during the coming summer on the soft fruits as they come in season. It is that portion of the experimental work managed by Mr. CHAMBERS, four-and-a-half bushels of fruit were stored in the chambers for 101 days, and 35½ bushels for fifty-six days. Mr. CHAMBERS states that some of the summer Apples left in the store until the close of the experiment were found to be sound, but were not so good in flavour, and were somewhat soft. On the other hand, the winter Apples were of as good flavour as when put in, and were quite as hard and sound.

Times.

THE NATIONAL CHRYSANTHEMUM SOCIETY'S annual report is a proof of the continued popularity of the flower, and of the remarkable vitality the Society possesses. Those who saw the wonderful display of plants and blooms on the occasion of the Jubilee show in November last year, will have some idea of the amount of work such an exhibition entailed upon the Society's committees and executive officers. This was done in a satisfactory manner, and from the report we learn that during the year there has been added to the reserve fund the sum of £55, making a total of £104 18s. 2d. The papers read at

the Jubilee Conference by Mr. GEORGE GORDON, Mr. C. E. SHERRIN, and Mr. NORMAN DAVIS are included in the information bound up with the report, such as the list of members, schedules of prizes, &c. The number of members continues to increase, as does also that of affiliated societies in Britain and abroad. The policy of the Special Classification Committee in regard to the classification of "certain varieties of doubtful character announced as incurved" is, perhaps, the most expedient one. It is best to take a broad view of the question, and in cases where there is doubt catalogue the variety as an incurved, leaving it to the judges to decide which are inferior at the exhibitions. It is, however, beyond dispute, that in the attempt to obtain increased size and variety among the true incurved section, there have been raised a number of varieties that are, properly speaking, Japanese incurved, and are the result of crosses between the true incurved type and the Japanese. The report of this committee explains fully the procedure that was followed, and the number of votes all these "doubtful" varieties obtained. During the present year there will be held four exhibitions—the first early in September, which is seldom creditable to the Society; the second, on October 12, 13, and 14; the third, November 9, 10, and 11; and the final on December 7, 8, and 9.

THE ELECTRIC LIGHT FOR FORCING-HOUSES.—In a recently-published work Prof. BAILEY asks, "Can the electric light stand for sunlight? Can it be profitably used at night and in dull weather to hasten the growth of plants?" The questions have received greater attention in the United States than elsewhere in the world. Experiments have been made at the Cornell Experiment Station, the West Virginia Station, and by W. W. RAWSON, an extensive vegetable grower at Boston. It is found that the electric light, both the arc and the incandescent, can be advantageously used upon Lettuce to piece out the sunlight in mid-winter. In various florists' plants it also produces earlier bloom. It is usually injurious, or has only negative results, upon Radishes, Peas, Carrots, Beets, Spinach, and Cauliflowers. Upon Lettuce the value of the electric light in hastening maturity is emphatic. Mr. RAWSON saves about a week upon each of his three winter crops by the use of three ordinary street lamps hung over a house 370 feet long by 35 feet wide. At Cornell the results upon Lettuce have been marked in many tests, and the gains in maturity have been as much as two weeks. It is found in every instance that the naked arc light—that is, a light without a globe—hung inside the house, injures the plants that are within a few feet of it, and tends to make all plants within reach of its rays run too quickly to seed. The use of a clear glass globe, however, overcomes all injury. The best results are to be obtained by placing the light—either naked or surrounded by a clear globe—a few feet above the roof. An ordinary 2,000 candle-power arc-light—such as is commonly used for street lighting—will exert a marked effect upon Lettuce for a radius of 75 to 100 feet, if the roof is clean and the framework of the house is light. The light may be allowed to burn all night. Incandescent lamps have the same influence as arc lights, but to a less degree. It will be found profitable to use the electric light for plant-growing, if at all, only in the three or four months of mid-winter.

DR. PAUL TAUBERT has died of yellow fever during his exploration of the little-known territory Amazonas, in Manos. His death occurred on New Year's Day last.

THE ROYAL GARDENERS' ORPHAN FUND.—We have the pleasure to announce that Mr. LEONARD SUTTON (SUTTON & SONS) has sent a donation of £100 to the Royal Gardeners' Orphan Fund; whilst his

* BAILEY, *Bulletin* 30 (August, 1891), 42 (Sept., 1892), 55 (July, 1893); also, "Electricity and Plant-growing," in *Trans. Mass. Hort. Soc.*, 1894. "Experiments with Electric Currents upon Plants," by CLARENCE D. WALKER, will be found in *Bull. Int. Bot. (1892)* and 23 (1893) of the *Mass. Hatch Experimental Station*. *The Forcing Book*, by L. H. BAILEY, p. 80.

† BAILEY, "Electro-Horticulture with the Incandescent Lamp," *Bulletin* 37 (July, 1894).

brother, Mr. A. W. SUTTON, has sent a similar amount to the Gardeners' Royal Benevolent. We are requested to remind our readers that the annual festival dinner of the Orphan Fund will take place on the 30th inst., at the Hotel Cecil, on the Thames Embankment, Charing Cross. Gentlemen desirous of attending the dinner will please communicate with the secretary, Mr. A. F. BARNES, Chiswick, or at the Hotel. Donations are still most thankfully received, and will be duly acknowledged.

FRUIT FROM THE CAPE.—Since our last report the "fruit ships" have arrived from the Cape: the first, the *Soot*, bringing 55 boxes of Pears and 294 boxes of white Grapes; the second, the *Ariondale*, bringing in 559 boxes of white Grapes. We are informed that, with the exception of 30 boxes, these consignments turned out in good condition, and realised fair prices. The faulty boxes above noted were very over-ripe, and hardly saleable.

PANSIES.—We have received from Messrs. DOBIE & Co., of Rothsay, some charming varieties of Pansies, especially noticeable being some of the new Victoria strain, which are of a brilliant rich reddish-brown hue, almost scarlet when seen under bright sunshine—a great acquisition. It has very dark brown velvety patches on three of the petals. A. J. Rowberry is a pure yellow self, of large size; Bullion is another yellow, with a few faint streaks of brown around the centre—it is a greatly-prized variety; Buttery, a large flower with a broad purplish-blue margin, and white central area, streaked with purple; Princess Ida, pale blue, and said to be very early; Marchioness, or Niphotos, is a white self; Cecilia, pale blue with a white centre; Mrs. C. F. Gordon, large, and of two shades of purple and blue; and Colleen Bawn, creamy-white, a large flower. All of the varieties sent very nearly approach the florist's perfection of form and colouring.

BELGIAN NOTES.—At the meeting on April 11 of the Brussels Orchidæene, one of the chief features was the display of *Odontoglossum*, including varieties of *O. crispum*, *Pescatorei*, *scoptruna*, *luteo-purpureum*, *Wilckeanum*, *triumphans*, *Ruckerianum*, and *cirrosum*. With the latter variety an entire table was covered by Messrs. LUCIEN LINDEN & Cie. These exhibitors also sent *Odontoglossum* × *Adriane*, the flower pale green, deeper at the edge, spotted with reddish-brown, lip white, in form like that of *luteo-purpureum*, the edge fringed and dotted with red. *O. crispum* from the same exhibitors had almost round petals, of a beautiful white colour, sepals flushed with violet, lip with four or five bright brick-red spots; the form of Paché. Dr. CAPART sent *O. Ruckerianum*, a very large flower, white, tinged with rose. MM. DALE-MAGNE & Cie. sent *O. Wilckeanum*, with a large and fine yellow flower. M. F. PAUWELS exhibited *Lycaste* species, with chestnut-brown sepals, widely edged with dull green, petals and lip white, with numerous spots close together in triangular form, dark rose; all the divisions are gracefully bent back. MM. LINDEN showed *Cattleya Triandri*, petals very wide, lip beautiful; MM. LUCIEN LINDEN staged *Trichopilia suavis*; MM. LINDEN, *Miltonia vesiliaria* var. *Bousiesiana*, a beautiful dark purple, the petals rather deeper than the sepals, a splendid flower; *Odontoglossum* × *Leopardinum* from M. WABOQUE is a fine variety. Other noteworthy plants were *Vanda suavis* var., with a spike of numerous and beautiful flowers, finely coloured, the sepals edged with rosy-lilac, the lip dark purple. *Cypripedium Albertianum* from M. DU TAZU DE TENDONC, and *C. Rothschianum* from M. WABOQUE, were fine specimens. *C. de B.*

M. SANDER & Cie.—This Druggers firm has now several houses full of imported Orchids, *Palms*, *Araucarias*, &c. There are some fine *Odontoglossum*, notably *O. Wilckeanum*, the flowers with large spots on a very clear ground; three *O. Ruckerianum*, with large flowers and a distinctly marked edge; *O. Hunnewellianum*, with two racemes with seven charming flowers; *O. crispum*, with the lip very broad, square, nicely marked; *O. triumphans*, clear yellow; a good *O. nutans*, and numerous *Lycaste Skinneri*. A large

stage in one of the houses is filled by *Ptychorhapis Augustæ*, a dwarf species with numerous delicately poised leaves. *Kentia Sanderiana* is of promise as an indoor plant; *Calanthe Alberti* and *Caroli*, *Kentia australis*, with twenty-three leaves; numerous examples of *Heliconia illustris rubricaulis*; ten thousand *Streptocarpus*, which will bloom presently; a fine strain of *Amoetochilus Sanderianus*, with free and large foliage; many *Macrorhizonia elegans*, *Hedera Madeniensis*, and other plants attracted my attention. *C. de B.*

SCOTCH FLOWERS.—Year by year the supply of spring-flowers to the Scottish markets increases; and year by year the supply from places outside Scotland grows less. The reason is not far to seek. The canopy Scot is now growing his own spring-flowers for his own markets, and pocketing the profit that used to go to the South of England and the Scilly Islands. Ten years ago the cut-flowers for Scotland came exclusively from the South. Now there are growers in Lanarkshire, Renfrewshire, Stirlingshire, Perthshire; and the nurseries are as complete and extensive as any in the kingdom. At Helensburgh, on the Firth of Clyde, one man alone has raised and disposed of 1,000,000 Tulips this season. The quality of the Scotch blooms is excellent. *Westminster Budget*.

MR. FREEMAN C. S. ROPER'S LIBRARY.—The library of the late Mr. FREEMAN C. S. ROPER, of Palgrave House, Eastbourne, came under the hammer at Messrs. SOHBEY'S, Wellington Street, Strand, on Friday and Saturday in last week, and attracted very general interest among scientific book collectors. It included a number of valuable works on botany and other branches of natural history, transactions of learned societies, and an exceptionally extensive and important collection of books on the microscope. The collection of 668 lots, representing some thousands of books and pamphlets, realised a total of £1308 15s. 6d. The more noteworthy lots of scientific interest, with the prices realised, are included in the following list.—*Benham and Hooker, Genera Plantarum*, 1892–83, and *Durand's Index*, 1888, £7 2s. 6d.; M. C. Cooke, *Handbook of British Fungi*, 1871, interleaved with copious MS. notes, and memoranda by Mr. Roper, with several drawings and a few plates added, with the supplemental volume, similarly annotated, with two autograph letters of the author inserted, £3 3s.; M. C. Cooke, *Illustrations of British Fungi*, 1888–89, with a few MS. notes and corrections by Mr. Roper, £17 5s.; M. C. Cooke, *British Fresh-water Algae*, 1882–84, and the supplement, 1887, £7; A. P. De Candolle, *Prodrromus*, 1821–73, eighteen volumes, £7 17s. 6d.; R. K. Greville, *Scottish Cryptogamic Flora*, 1823–28, £5 5s.; *Grevillea*, a monthly record of *Cryptogamic Botany*, vols. i. to xxii., 1873–93, £3 15s.; W. H. Harvey, *Phytologia Britannica*, 1846–51, £3 16s.; Sir W. J. Hooker, *Journal of Botany*, 1849–57, £3 5s.; *Journal of the Proceedings of the Linnean Society*, Botany, vol. i. to xxx., and five parts of vol. xxxi., and Zoology, vol. i. to xxiv., with general Indices and Catalogue of the Library, £11; Lindley and Hutton, *Fossil Flora of Great Britain*, 1831–87, £2 6s.; J. Gerarde, *The Herbal, or Generall Historie of Plantes*, first edition, a sound and clean copy, in old calf, 1597, £5 12s. 6d.; a copy of the 1633 edition, £3 5s.; a good copy of *The Grete Herbal*, printed at "Southwarke," by P. Treveris, 1526, extremely rare, the first English herbal, £39; Dr. R. K. Greville, *Collect Works on Diatomaceæ*, with obituary notices of the author, by Drs. Balfour and Lankester, 1855–56, interleaved with MS. notes, and an Index by Mr. Roper, £3 5s. (this lot is from Dr. Greville's own collection, and is probably the only complete set in existence); seven volumes of papers on *Diatomaceæ*, *Desmidiæ*, &c., from the *Annals and Magazine of Natural History*, by De Bréisson, Gregory, Bailey, and others, with Mr. Roper's notes, &c., 1843–69, £3 5s.; Pritchard's *History of Infusoria*, 1861, with two interesting autograph letters of Mr. Ralf's inserted, £2 8s.; W. Smith, *Synopsis of the British Diatomaceæ*, 1853–56, with numerous MS. notes and additions by Mr. Roper, £3 3s.; *Enty Society*

Publications, from the commencement in 1845 to 1893, £28; P. A. Saccardo, *Sylloge Fungorum*, 1882–96, £27; *Journal of Botany*, edited by Dr. B. Seemann, H. Trimen, and J. Britten, from its commencement in 1863 to October, 1896, £21; J. Sowerby, *English Botany*, 1790–1863, with the general indices, and the rare supplement, in five volumes, and also Rev. M. J. Berkeley's *Observations of British Algae*, forty-two volumes in all, interleaved, and with numerous valuable MS. notes by Mr. Roper, £36—this copy has the supplemental Nos. 2995, 2996, 2997, and 2998 (with letterpress), which have not been published, and are excessively rare; a copy of the third edition of the same work, 1863–92, with supplement by N. E. Brown, £15 10s.; E. Claparède et J. Lachmann, *Études sur les Infusaires et les Rhizopodes*, 1858–61, £2 2s.; W. J. Hooker, *British Phycogamia*, 1846, with pencil notes by Mr. Roper, £4 2s. 6d.; Bruch, Schimper, & Guntzel, *Erpologie Europa, seu Genera Muscorum Monographice Illustrata*, 1836–64, six volumes, £18 5s.; Dawson Turner, *Fungi*; or *Sea Fungi*, 1808–19, four volumes, with 268 plates, coloured from Nature, £3 3s.; J. Sowerby, *Coloured Figures of English Fungi*, 1797–1815, with 440 beautifully coloured plates, in three volumes, interleaved, and with numerous notes by Mr. Roper, £7 10s.; and W. Turner, A new *Herbal*, wherein are contained the names of Herbes in Greke, Latin, English, Duch and Frenche, 1551, first edition, £6; another copy of the first two parts, but imperfect, £5; and a copy, not quite perfect, of the edition of 1568, £6 6s.

THE LATE COLONEL TREVOR CLARKE.—The collection of Orchids, greenhouse and other plants, also four conservatories at Welton Place, Northampton, which belonged to Colonel TREVOR CLARKE, recently deceased, will be sold by auction, at the instance of the executors, on Thursday next, April 29. The late Colonel was an ardent plant-lover, and his collection, we suspect, contains some uncommon species.

BERLIN HORTICULTURAL EXHIBITION.—The great exhibition to celebrate the seventy-fifth anniversary of the Horticultural Society of Prussia, from April 29 to May 9, will be one of the greatest shows of this year. We recommend all visitors of the Hamburg exhibition, which opens on May 1, to go first or afterwards to Berlin, because the Berlin exhibition opens on April 28, and lasts till May 9, whilst the Hamburg show does not open till May 7. Never, perhaps, have so many losses been shown as are likely to be exhibited, together with floral arrangements, also forced vegetables, as well as garden plans at a spring exhibition at Berlin. The total arrangements are very beautiful. The exhibition will be opened by the Empress on the 29th is to be a great meeting for discussion of—1, exhibitions; 2, public sales; 3, of schools for young gardeners.

BOOK NOTICE.

DICTIONNAIRE ICONOGRAPHIQUE DES ORCHIDÉES.

Two fresh issues of the excellent illustrations of Orchids by M. A. Goossens, accompanied by the descriptive letter-press by M. A. Cogniaux, have reached us. They are labelled for *Dendrobium* and *Miltonia*, but, as usual, contain plates for passing into portfolios already issued, and lettered for other genera, as well as those destined to remain in the portfolios in which they are sent. Each issue is accompanied by the little "Chronique Orchidicque," of a suitable size to go in the portfolios, and which it is intended to send with each fresh issue, and thus convey current information relating to Orchids. All the plates issued are well up to the high standard of excellence seen in their predecessors, and although there are no remarkable novelties among the things depicted, yet they form a worthy continuation of interesting series in their different classes. Among the subjects are *Lycaste Skinneri* and its varieties *alba*, *Rugina*, and *delectatissima*; *Cypripediums* are

continued with *C. Erato*, *C. × Zampa* var. *Pbidias*, *C. Lecanum* var. *Albertianum*, and *C. × trimumphans*. The history and essential characters of *Masdevallia* are given, members of the genus well illustrated being *M. Davisii* and three varieties of *M. ignea*. Under *Laelia* appear *L. autumnalis* and its variety *alba*; *Laelia Gouldiana* and *L. amanda*, which is more probably a natural hybrid between *Cattleya intermedia* and *Laelia Bouthiana*, than a true *Laelia*. *Cattleya elongata*, which would more stir than it was worth recently, as *C. Alexandrie*, appears under its proper name; and other things illustrated are *Odontoglossum × Ruckerianum*, *O. Coralline*, *Miltonia × Blenana*, *M. vexillaria Leopoldiana*, *Laelio-Cattleya × Corbellensis*, *L. C. albaneusis*, *Dendrobium noble* var. *Ballianum*, and varieties of *Dendrobium Phalaenopsis*.

ARTIFICIAL MANURES.

At the meeting of the members of the Royal Horticultural Society at the Drill Hall, on April 13, a lecture was delivered by Mr. J. J. Willis on "Artificial Manures, and their Bearing upon Horticultural Practice," of which the following is an abstract:—

The lecturer stated, that one of the very first requirements for a healthy condition and a subsequent successful propagation of any plant, consists in adopting a well-devised system of soil-preparation and of manuring. There can be little doubt but that an indifferent system of soil-preparation and of the feeding of plants is at the root of a great many well-founded complaints of failure in various branches of gardening, and of fruit-culture in particular. Our views as to use of manures have undergone a considerable transformation during the past few years. Scientific investigation has succeeded in solving a number of most important questions, and we have in consequence been led to adopt new and clear principles relative to the application of manure to our various cultivated plants. Yet, notwithstanding the advance in manorial knowledge, our gardens, orchards, conservatories, and vegetable areas are frequently treated with but little consideration as to their requirements in the matter of plant-food. They are dressed with large quantities of stable manure or vegetable compost, which may contain but a small proportion of food-sustaining constituents; no thought is given to the waste of certain ingredients, which must necessarily ensue from an excessive manuring with such materials, and how much more useful this manure could be rendered by an admixture with suitable artificial fertilisers.

A system of manuring may be called well-devised or rational when it is based upon the results of a careful examination into the chemical composition of the plants under cultivation, and on a due consideration as to their natural capabilities for availing themselves of the needed food, both from the atmosphere and from the supplies within the soil. The object sought in cultivating plants is usually to produce a growth in some of their parts that is unnatural to the species in its native habitat. This part may be the flower, the seed, the fruit, the stem, or the leaves; or, again, the object may be to obtain an extra large amount of sugar, as in Grape production; or of starch, as in the growth of Potatoes; or it may be to produce leaves with more cellular substance and less fibrous matter, as in Lettuce, Spinach, Celery, Asparagus, &c.; and all this means in the end nothing less than that the opportunities of the horticulturist for controlling the quality of his crops are daily improving.

Each plant has its special wants at different stages of its development. Succulent and rapidly-growing vegetables require an abundant supply of nitrogen in an available form during their early periods of growth; flowers and fruit trees require phosphatic food when blooming and developing seeds. Grape-vines need a large amount of potash during the formation and maturing of the Grapes for the production of sugar; whilst Potatoes require nitrogen and potash for the production of starch in the tubers.

The lecturer next called attention to the chemical composition of various garden products, and to the

amount of fertilising constituents they require for their successful cultivation, and pointed out the fact that in order that plants may obtain all the food materials they require, it is necessary that there be a large excess of them in the soil, probably double the amount shown by an analysis of the crop grown.

The essential elements of plant-food are not needed by different crops in the same invariable proportions at the various successive stages of growth, but are wanted at different periods of their life in different absolute amounts and in different relative proportions; hence it is of the utmost importance that artificial manure should be given at the proper time, and in suitable and fixed proportions, and not at the mere fancy of the grower.

Attention was then directed to the nature and composition of the principal varieties of artificial manures in the market, and to their influence upon the growth of particular crops. The subject was illustrated by various stencilled diagrams, showing experiments on Potatoes in light and in heavy soils, also on Tomatoes and Peach trees, for particulars of which we must refer to the published report of the Society.

The lecturer concluded his remarks by stating that a careful consideration of the different points could not fail to impress the fact that to manure horticultural soils efficiently means to-day something more than to incorporate into them an exceptionally liberal amount of such a varying substance as farmyard manure, vegetable composts, or the like, which may take many years to yield all the effects of which they may be capable. Further, an excessive accumulation of organic matter in the soil is apt to turn it into a breeding-place for injurious insects, or of parasitic productions.

A moderate use of natural manures, supplemented by a suitable addition of concentrated commercial fertilisers, for the purpose of rendering the former more rapidly available, and to force particular forms of garden produce "out of season," should commend itself to the horticulturist on account of the directness with which he can thus reach the object in view. Both good economy, and the preference for a healthy and vigorous condition of our cultivated plants, advise a change from an indifferent system of manuring to one of a more rational character; and it is hoped that this lecture will assist in assigning to these concentrated fertilisers their proper place among the manures of the garden, and indicate how they may be applied efficiently and economically, besides drawing the attention of horticulturists and orchardists to the great value of these manorial substances, which have hitherto been overlooked or but insufficiently appreciated.

SCOTLAND.

NOTES FROM ROYAL BOTANIC GARDEN, EDINBURGH.

Thunbergia mysorensis.—A plant in the stove in this garden is now blooming freely, where it is planted under the stage and trained upon the roof. In this position the racemes are well shown. They are produced from the old wood, and as soon as the inflorescences are discernible, it is advisable to cut out some of the superfluous younger shoots. The corollas are yellow, with a reddish-brown border, about 1½ inch in length. The racemes sometimes bear thirty blooms; and hanging beneath the dark green acuminate elliptic foliage are very conspicuous. It is a very easily grown plant, requiring plenty of sunlight at all times. Under its synonymous name of *Hexacentris* it has been figured in *Bot. Mag.*, t. 4786, which represents the flowers as pure yellow. Under cultivation it is a variable species. The blue-flowered *T. aurifolia*, another good climber where room can be given it to run freely, is also in bloom.

Cissarea carolinensis is probably the earliest to bloom in this genus, and is consequently a valuable plant. It is a remarkably showy plant, with large, brilliant scarlet corollas. Large tubers are formed, which, after flowering, gradually lose their strong stems; and large, light green, hairy foliage. They should

then be rested in a warm-house until they again commence growth, which generally takes place early in January. They will then need to be shaken out and re-potted. A light position in a moist warm atmosphere suits them well.

Tiburnum macrocephalum has been in flower here for the past few weeks. It is trained against the wall in the corridor, and the growth of the plant seems peculiarly adapted to this method. The foliage is almost hidden by the snow-white masses of flower. Although not difficult to cultivate, this species is not a quick grower. Its floriferousness may be imagined when I say that the plant here, only about 3 feet high, carries more than thirty trusses of flowers. It is hardy, but is not common in gardens. *V. m. v. Keteleeri* is the sterile form, and is less showy than the type.

Aristolochia Westlandi should be trained upon the roof in a stove. The woody stems are covered with brown hairs; the light green leaves are long, and linear-lanceolate in shape, and placed at considerable intervals upon the stems. In the axils of the leaves are the peduncles bearing single flowers, the perianth being about 6 inches long and 4 inches broad. It is purple, with yellowish veins, the back surface being browner in colour. Mr. A. B. Westland, after whom it was named, discovered the plant in the Kwangtung province of China, and it was figured in the *Bot. Mag.*, t. 7011, from a plant flowered at Kew in 1888. Planted out, it quickly forms a large plant, and if freely exposed to the sun, flowers profusely. *R. L. H., Edinburgh.*

HOME CORRESPONDENCE.

A REMARKABLE MALE FERN.—I have in my possession young plants of a variety of the crested Male Fern (*Lastrea pseudo-nigra cristata*) raised by Mr. Cropper, which are of such a remarkable character as to merit particular mention. In 1895 Mr. Stansfield mentioned the appearance of this Fern in collections, and sent me a small piece of one of the pinnae as material for culture. I pegged this down in sterilized soil, and in the following spring quite a bunch of prothalli had been developed from the tips of the tiny divisions, and a number of young plants were appearing. This season, several of these are growing into plants, thus enabling me better to judge their peculiarities. In the first place, then, it is decidedly the most beautiful crested form of the species, not merely the pinnales, but also the crests being delicately frimbriated. In this respect it excels Mr. Cropper's previous acquisition, *L. p. m. cristata frimbriata*, in its own particular line. Whether this form is the parent, or whether it is a direct sport from the old *L. p. m. cristata*, is not, I believe, determinable, but there is a certain difference of form which inclines me to the latter belief. Apart from its beauty, however, it is distinguished by the fact that it is the first Fern in which "apospory" has been noticed on a crested form as a permanent feature. As a temporary feature in the young state, I exhibited some time since a seedling of *L. p. m. cristata* bearing prothalli; but the resulting plants grew out of the habit. The Fern under notice, however, has all the tips of its prothallia, crests and all, quite translucent, and these at the slightest encouragement fan out into prothalli, and yield young plants. Another important feature is that these young plants are produced asexually, i.e., without sexual action, so that we have the two phenomena distinctly correlated here. So second, too, is the plant, that I have in my cultures instances of these youngsters being produced from prothalli formed on small fronds, and which have not been pegged down, the optical effect being that of the bulbils of *Asplenium bulbiferum*, with, however, the important difference, that a prothallus precedes the appearance of the bud, and that this is on the under side. The prothalli, when pegged down, seem also capable of indefinite multiplication on their own account, the result of a minute piece being, in my case, a small thumb-pot full of creeping prothalli, which throw up a number of young Ferns from the buds they freely produce as they proceed. These buds throw up primary fronds, which differ from the normal type, and even from those of *L. p. m. cristata* itself, since they are really stalked prothalloid fronds, with thin ragged edges, and even these are capable of developing buds, and a second generation before, as it were, they are themselves fully grown and into existence as Ferns proper

The life-cycle in this case is much shortened. *L. p.-m. cristata* has been demonstrated to be hardy to the extent of spragons, but it is remarkably fertile in spores, and the prothallus is produced from them in the usual manner. In their descendants, however (whether it will produce spores or not, I cannot yet say), the spore is eliminated altogether, and the prothallus is produced directly from the fruit, and becomes merely a medium for bearing asexual bulbils. This peculiar example of reproductive variability has a further interest to the evolutionist, as I understand that Mr. Cropper's Fern-house, in which it originated, is one where the shade and humidity—so congenial to Fern-growers—are extreme, so that in this instance, at any rate, this sport, as well as the previous one of fibrillate peculiarly delicate texture, seems to be the direct outcome of its fostering environments. In this connection, too, Mr. Cropper's remarkable fibrillate *Scolopendrium* may be cited. More immediately, perhaps, I should mention that the asexual seedling *Lastræa* above cited originated with me in a close Warden case. With these exceptions, however, the asexual spores so far observed have been found wild, and do not owe their peculiarity to high culture. It also becomes a question if such sports as these are the direct results of close culture, or whether their particular characters must not be deemed as "acquired" ones? The asexual, however, which is co-induced, renders the question of their transmission by inheritance an open one, the generations being practically continuous. *Chas. T. Drayner, F.R.S.*

APPLE BRAMLEY'S SEEDLING.—Mr. Merryweather is sorely correct in his quotations respecting the merits of this Apple, as stated by me on p. 240. I there conveyed my impressions concerning this Apple here (South Bucks), and what I could gather respecting it in some neighbouring districts. I should have said that my remarks applied to trees grown as bushes or pyramids; from the nature of its growth, it appears better adapted to orchard standard trees. I believe in Midland districts Bramley's Seedling bears heavily on standard trees, and we all know that some varieties of Apples succeed in certain localities, and not in others. I mentioned Lane's Prince Albert because this variety, planted by me in two different gardens alongside the variety in question, and under precisely similar conditions, is always a regular and heavy cropper (some fruits of which I have yet in store), while Bramley's has never produced a full crop. The awarding of the prizes for this Apple at the Crystal Palace Fruit Show to southern growers does not prove it to be a good or rying variety in those districts, although it may be so. *C. H.*

To the note in the *Gardeners' Chronicle*, p. 240, by your correspondent "C. H.," respecting Bramley's Seedling Apple, I should like to add my testimony. I have found the tree to be a good bearer as a bush and as a tree on the Crab stock; but I am unable to speak of its good-keeping qualities. Here the fruit gets soon spotted, turns soft, and does not keep after it is stored for so long a time as it is represented to keep, which may be due to our heavy, loamy soil, and to moistness of the climate. I have seen fine fruits of this variety in Nottinghamshire, in which county it is thought a great deal of, and I am of the opinion that "C. H." is that it is better suited to the midlands than to some other parts of the country. The trees of which I write have been root-pruned. Lane's Prince Albert is a first-class all-round Apple, and anyone wishing to plant a good cropping and keeping variety cannot do better than plant some of it. The fruits keep better at Liffon than Bramley's Seedling. *F. Q. C., Liffon Park Gardens, Liffon, North Devon.*

THUYAS.—I enclose a spray of *Thuya gigantea* from a tree planted on the same day as *T. japonica* (Standishi), in the spring of 1873, and growing a short distance from each other on the lawn at the gardens. As growing here, under exactly the same conditions, in a light sandy loam, rather too dry for luxuriant growth of an *Arbor-vitæ*, especially when combined with our comparatively dry climate, the difference between the two species is striking enough! and I can tell the one from the other by their distinctive habit and appearance, as far as I can see them. You will notice the silvery underside of the sprays of *T. Standishi*, a characteristic entirely absent from *T. gigantea*, so far as I have observed it in any part of Britain. Another point of difference that is not mentioned in the article is, the cones of *T. gigantea* are always more or less upright, or are seen on the

upper side of the branches; while the cones of *T. Standishi* are as invariably drooping, so far as they have been produced on the specimen here. The last may not be a permanent characteristic of *T. Standishi*, although it has been constant here since the tree began to produce cones a few years ago, 1892. Then, the rate of growth, as the heights marked on the labels indicate, of *T. gigantea* is about double that of *T. Standishi*, growing under similar conditions for twenty-four years. Of the two species, *T. Standishi* is much the better ornamental Conifer for gardens and grounds of limited extent, while *T. gigantea* is undoubtedly the best forest tree among the *Arbor-vitæ*. I am also sending a few sprays of two other very ornamental *Arbor-vitæ*—one, No. 3, labelled *T. occidentalis* var. *picata*, and the other, No. 4, labelled *T. occidentalis* var. *Warreana*; both the same age, and planted at the same time, in 1873, as the two first mentioned. All of them were got from the late firm of Billantey & Son, nurserymen, Dulkeith, and were by them believed to be true to name at that time. *T. gigantea*, as already pointed out, grows about twice as fast as *T. Standishi*; about four times faster than *T. occidentalis* *picata*, and about five times as fast as *T. occidentalis* *Warreana*. They are all very distinct types of *Arbor-vitæ*. *T. occidentalis* *picata* is a particularly handsome small tree, a perfect golden-coloured cone at this season of the year, and maintains the golden tinge for a long period annually. *T. Warreana* is of a more bushy or spreading habit, and forms a distinct and pleasing object on a lawn among Conifers of a taller and more pyramidal growth. *Milobothrin.*

THE RENAISSANCE OF THE HOLLYHOCK.—No hardy plant at present in cultivation could be of more use to the gardener, in these days of mixed borders and cut flowers, than the Hollyhock; and any who may be desirous of having the same should begin with seed, which can be purchased from the seedsmen. The best time to sow seeds is in the second week of March, the seed-pot being put into heat. When the plants are large enough, they should be potted first into 60's, and then into 48's, and hardened off in time to plant in the borders in May. The stations for the plants should be trooped and manured, and the plants receive good attention throughout the summer, affording water and manure when necessary. During the winter the plants may be protected with branches of Spruce Fir stuck in around them. The result the second year will doubtless exceed the utmost expectations. In order to maintain a stock of vigorous plants, seed should be sown annually, and to grow the plant for a longer time than two years on the same piece of ground. Nothing leads to an attack of the *Peronospora* sooner than growing the plants on the same ground for several years. The days of budding, striking from cuttings, and grafting Hollyhocks, are past and gone, as much as the striking from cuttings of *Inerarias* or herbaceous *Calcarias*. *D. L. M.*

THE LATE COL. TREVOR CLARKE.—How admirably do you describe this deceased gentleman as a "lovable man." He belonged to a gradually decaying generation of real amateur horticulturists. Among his contemporaries were the Rev. J. M. Berkeley, Mr. Wilson Saunders, Mr. Bateman, Mr. G. F. Wilson, and some others, dead and living, who were the lights of the Royal Horticultural Society in the old South Kensington days. It is to be feared that we shall not soon look on their like again. The present generation of young gardeners hardly know of these gentlemen. They were potent forces in horticulture in what now seems to be the long ago. A privilege was it—not to be lightly esteemed—in the old Kensington days, to listen to the addresses which these gentlemen would often give in the old council chamber on the subjects shown at the meetings. Would that some such running comments from such able and enthusiastic exponents were possible now! There is, at any rate, very much more of material to furnish texts for the eloquent than was found at South Kensington twenty years ago. If Mr. Berkeley were an able exponent of fungi, Mr. Bateman knew what to say of the Orchid, and Major Trevor Clarke generally of everything. We find in the well-known Red Celery which bears his name (and may it ever do so) one little memorial of his usefulness; and a once universally-grown *Begonia*, wretchedness, reminds us of the deceased's home. By death, horticulture is thus made distinctly the poorer. We have too few Trevor Clarkes in our midst that we can lose them with equanimity. *F.R.H.S.*

VOLES AND MICE.—I am somewhat puzzled by the appeal of Messrs. Laing & Mather, Kelsø,

for information about the vole, and at their postulating the distinction between a vole and a mouse—first, because when the farms in the South of Scotland and about Kelsø were, a few years ago, devastated by voles, a commission of inquiry sat to investigate the subject, and everything was elicited in the evidence given that could be, and published in every local paper, voles at that time being the staple topic there among farmers and gardeners. Plans for destroying the vermin were also earnestly solicited at the same time, and if your correspondents knew of an "ancient" but successful method of killing them by thousands they have kept the secret till rather late in the day. Second, as to the vole being a distinct "species," nothing has been better ascertained than that the vole differs structurally from a mouse about as much as a sheep differs from a cow, and if Messrs. L. & M. will open the mouths of the first vole and mouse they catch, they will see one of the principal differences between the two. I still doubt the vole's climbing powers, and as your correspondents have reduced the height of the damaged Scots Firs from 4 feet (which statement they *firmly* hold) to some 15 inches, we seem to be coming to an agreement on that point. I apprehend, from the prominence given to the subject in both English and Scotch papers by Messrs. L. & M. of late, that our old friend the vole is somewhat of a stranger to them; but I am a little mystified, at the same time, by their present familiarity with its habits and proclivities. Their allusion to "well-known facts" about the vole's tree-nibbling propensities is hardly reconcilable with the fact of their having had to send some 50 miles away to know what was eating their own trees. Was it either the voles or the mice that did the mischief? According to the *Evening World*, April 2, a whole "horde" of voles had invaded L. & M.'s nursery, yet those "close observers" they mention, had not seen so much as one vole on the damaged Scots firs. I surmise this because they did not suspect the cause before writing to Mr. Dunn, and are, probably, only blaming the voles now because they trapped them between the rows. We have similar large quarters of Scots firs in the home nursery here, and mice and voles in plenty, but there was no nibbling during the snow storm, nor since, nor at any other time. *J. Napton.*

THE JUDGMENTS OF THE FLORAL COMMITTEE.—In his letter to you on *Thilpa Kaufmanniana*—with all of which I entirely agree—my friend, Mr. Elwes, tells how his specimen of *Lilium Thompsonianum* was treated by the Horticultural Society. I knew he was going to exhibit it, and was surprised to find that it neither received medal nor commendation, but that it was entirely ignored. I doubt if the committee will soon have any plant so interesting brought under its notice. I am induced to notice it, because I also have a plant now in flower. Mine is in the open air, and I have had it many years, but this is the first time it has flowered. It is perfectly hardy, but probably does not flower till of good age. I have one spike with over twenty blooms on it, about 3 feet high, but unfortunately injured by the late gales. The colour of my flowers is paler than as figured by Royle and in the *Botanical Register*. I should like to know whether it has flowered elsewhere in the open ground. *Henry N. Elliott, Cambridge, Bitton.*

TRANSPLANTING BRACKEN.—Mr. B. Goldring, p. 260, whose suggestions on the formation and furnishing of landscapes we all gladly welcome, gives some good advice on this interesting subject; though perhaps he hardly goes far enough in the direction that mass is right, that is, success in the transplanting of Bracken. For instance, sows a foot broad or wide (square), where the Bracken is thickest, is capital advice; but why limit the depth of the sods to not less than 6 inches? A foot or more in depth is far safer and more successful than 6 or 8 inches. In fact, if we are to measure our sods at all, let it be by cube, not square measure. Or if there is to be any difference, as there well may be, let the depth exceed the length and breadth of the Brackes-sods or masses of creeping rhizomes and roots. Neither should the sides of the sod be cut by the spade, previous to or in the raising. This, no doubt, facilitates the raising of them, but the cutting and sawing of the sides and cuts off the black creeping rhizomes by scores, thus depriving the Bracken of the power of taking speedy and complete possession of its new quarters. My experience is, that the bigger, the deeper, the rougher the edges and bottom of the sods and masses of the Bracken, the sooner it takes possession and furnishes its new home. For

establishing new plantations, back a cart into a thick plantation of the Fern, and load it with pieces of about a yard square of Bracken and soil, and empty the cart where a new colony is wanted, and leave it alone, and your object is gained, the more surely if all regular planting be ignored. Those who want a large mass or acres of Bracken can gain such through accumulation or extension on the same lines. The great merit of this rough-and-ready plan of clothing woods and landscape with this grandest and most graceful of all our hardy ferns is, that we carry the soil with the plants en masse, and they seldom stop growth to look behind them. Why should they? The environments and conditions of growth are transferred with the plants, and the Brackee establishes itself in its new home as a matter of course. True, many of the Bracken pieces may be upside down. But their re-adjustment to novel conditions is not beyond the powers of Fern nature and life. Neither am I so sure of April planting as Mr. Goldring. So soon as the cold frosts are matured the transplanting of Bracken en masse may be begun, the end of October and all through November, being the best season. Perhaps the earlier the better, as this affords time for natural consolidation of the soil and roots, and enables the one to take more kindly to the other before the active growing season sets in. Peaty soil and light fine loam enriched with the humus of some decayed leaves, known by gardeners as fluky leaf-mould, is the most congenial for Bracken in old plantations or new. The plant dislikes strong clay, or sodden, wet soil; though one great advantage in planting in solid yard wide masses is, that colonies of Bracken may thus be established on the surface of unequal and unsuitable soils and positions. *D. T. Fish.*

NURSERY NOTES.

MESSRS. J. CHARLESWORTH AND CO.,
HEATON, BRADFORD.

CHANGING continually, this enterprising firm have always endeavoured to keep abreast of the times, making specialties of those plants which are popular or most in demand, and taking up each new venture energetically. A few years ago the stock consisted almost entirely of *Odontoglossum crispum* and other showy *Odontoglossums*, *Cattleya Dowiana aurea*, and shorty *Orchids* generally, of which their collectors kept them well supplied. But during all this time, Mr. Charlesworth was pursuing the hobby of raising cross-fertilised *Orchids*, and in the earlier stages making quite as many failures in hybridisation as fall to the lot of beginners generally. But careful observation and experiment brought success, and now Mr. Charlesworth asserts that within reasonable limits he can, with certainty, cross and raise plants from seed of anything he wishes to increase. Seedlings of *Cattleyas*, *Leclias*, *Epidendrums*, and *Sophrontis* crossed in every conceivable way occupy a long range of houses, specially constructed for the culture of the hybrids, some 4000 of which, each with its record-ticket, and each standing on an inverted flower-pot, occupies the two first divisions of the range, the seedling plants and innumerable tiny seedlings of later sowings occupying the private houses beyond. *Leclia* (*Braassovola*) *Digbyana*, which gave such good results in the *Leclio* × *Cattleya* × *Digbyana* × *Mossie* raised by Messrs. James Veitch & Sons, have been used as one of the parents in a large number of crosses, some of them very strange combinations, and little plants of each, 2 inches or so in height, have been raised, and now occupy single pots. *Epidendrum vitellinum* has also been successfully crossed in several ways, and little plants secured; and all are in such thriving condition, that the wisdom of putting up the new range, which is now nearly completed to meet the rapid demands for space, is plainly demonstrated.

In the next house, in which the flowering specimens of hybrids are kept, is a fine stock of large plants of *M. Mantia's* *Cattleya* × *Mautinii nobilior* (*Dowiana* × *Boweringiana*), a richly coloured and fragrant winter flowerer; *Sophrone* *Leclia* *Mariottiana* (*L. davyi* × *S. grandiflora*), bearing pretty scarlet flowers; a lot of *Leclio* *Cattleya* × *Andreana* and *L. C.* *Corleillensis*, two pretty continental hybrids; and from

the same source *L. C.* × *intermedio-flava* and *L. C.* × *Bertha Fournier* (*L. C.* × *elegans* × *C. aurea*), of which much is expected, and truly it is a noble-habited plant, which will probably flower this year. At the end of the house is a batch of the slender-stemmed *Epidendrums* intended for crossing, commencing with the pretty little white and violet *E. Endresii*, only a few inches high, and passing upwards to the yellow *E. xanthinum*, the scarlet *E. radicans*, the light tinted *E. paniculatum*, the purple *E. arachnoglossum*, and *E. cinctum*, which some class as the same species, but which are here distinct, in size and intensity of colour at least; and behind all, and sending its sprays of flowers forward, are some plants of *E. × O'Brienianum*, the first Veitchian cross of the section.

Among the hybrid *Cypripediums*, *C. Jeanette* (*Leucanum* × *niveum*) is a charming white flower, dotted with magenta-roses. Many others of the *C. bellatulum* section of crosses are in bud, some of which will probably be new, and others, doubtless, similar to *C. × Chas. Richman* and others already named.

In the houses devoted to importations was found a fine lot of *Cattleya Mendeli*, and an equally good one of *C. aurea*, and batches of most of the other showy *Cattleyas* and *Leclias* in smaller numbers, especially *L. purpurata* and *L. tenebrosa*, both of which promise to give a grand display of flowers in their season.

In the cool-houses noted in bloom were many *Odontoglossum crispum* of the best type, some of them finely spotted; *O. Halli*, *O. citrosum*, *O. Polyanthum*, *O. Rossi majus*, *O. Cervantesii*, *O. aspersum*, *O. Edwardi*, *O. × Andersonianum*, &c.; and a number of the cool-house *Oncidiums* of the *O. Marshallianum* section. Among the *Masdevallias* were *M. Veitchi grandiflora*, *M. peristeria*, *M. × faicata*, *M. Chestertoni*, *M. bella*, and *M. Winniana*, the darkest and best of its section.

Among the *Dendrobiums* in flower were a number of hybrids of the *D. × splendensimma* type; a batch of *D. Hildebrandi*, which, generally speaking, is not a favourite, but one variety in the batch was remarkably showy, and as large as *D. tortile*, with which it seems to suggest that *D. Hildebrandi* has an origin in common. Other good batches showing flower remarked were *Oncidium concolor*, *Odontoglossum citrosum*, and some of the dwarf *Vandas*, among which in bloom was a plant of the pretty light rosy-lilac *Vanda* × *Charlesworthii*.

Here, as in other places where lath-roller blinds have been tried, they are found to greatly simplify *Orchid* culture, as the houses can be shaded without interfering with the necessary and all-important matter of ventilation. On the *Orchid*-houses, too, it is said that they are a great safeguard against excessive cold at night in winter, and consequently on the most important houses they are left up permanently.

AMERICAN NOTES.

NEW HORTICULTURAL BOOKS.

AMERICAN horticulturists have been more than usually prolific this spring in the publication of new books. Those of most interest are Professor Goff's *Principles of Plant Culture*, Professor Bailey's *Forcing Book*, Professor Green's *Vegetable Gardening*, and Professor Rolfs' *Vegetable Growing in the South for Northern Markets*. All these are written by professors of horticulture in our agricultural colleges. This is a fact worthy of notice. A few years ago our American rural books were written mostly by men like Peter Henderson, Andrew S. Fuller, and Horace Greeley—men who were not professors of horticulture, and some of whom heartily despised the "scientific farmer" and the college graduate. What a profound change has been wrought in fifty years! All of the books named above, the *Forcing Book* excepted, were written as text books for the classes of the respective authors. Professor Goff's work is an admirable elementary treatise of those parts of chemistry, botany, horticulture, and related subjects necessary in short courses of instruction, or with pupils of very

moderate attainments. Professor Green's book gives directions for the practical management of vegetables in the inclement climates of Minnesota. Professor Rolfs teaches horticulture in Florida, and his book therefore presents the sharpest contrasts to Professor Green's work. Both are necessarily quite local in their practical usefulness. Professor Bailey's *Forcing Book* endeavours to give plain directions for all the work connected with forcing vegetables for market in glass-houses. All these books should be commended for good printing, and for abundant and useful illustrations. *F. A. Waugh, Burlington, Vt.*

LAW NOTES.

A TREE-LOPPING CASE.

MRS. FLORENCE WALLIS and Captain Robert King are next-door neighbours at Elm Tree Road, St. John's Wood. Their gardens are separated by a wall and a row of nine Lime-trees. These grow in Mrs. Wallis's front garden, at No. 10, and provide for her an agreeable seclusion. On Tuesday, April 13, she sued Captain King in Marylebone County Court for damages for "trespass," and sought an injunction to restrain him from lopping her Lime-trees. The parties were represented by solicitors.

Plaintiff said she had no objection to Captain King pruning away overhanging branches which might prevent his flowers growing. But his gardener mounted a ladder, and sawed off the tops of her trees, and changed the appearance of her garden.

Assistant-Judge Fitzgerald said, if defendant had only pruned overhanging branches he would have been within his legal rights; but he believed defendant lopped them also, and for this plaintiff was entitled to damages. He allowed £3, and granted the injunction. *Daily Mail.*

TRADE NOTICE.

MR. C. SPRENGER, formerly partner in and technical manager of the firm of Damunati & Co., San Giovanni à Teduccio, near Naples, has ceased his connection with that firm, and has established himself at that place as a landscape gardener, florist, &c., and cultivator of new plants for sale.

SOCIETIES.

MEETING OF THE GHENT CHAMBRE SYNDICALE.

APRIL 5.—At the meeting of the Chambre Syndicale des Horticulteurs Belges, on the above date, the following awards were made:—Certificates of Merit were awarded to M. A. Van Inshout, for *Mitrois vexillaria* var. *rubra*; M. L. De Smet-Duvivier, for *Anthurium Scherzerianum* var. *Madame De Smet-Duvivier*; M. A. Van Inshout, for *Randia mandata*; M. Ch. De Loore, for *Aecia Latrobei*; M. A. Van Inshout, for *Cattleya Luddemaniana*; Comte Joseph de Henningpo, for *Odontoglossum Wilckeanum* var., and for *Oncidium sarodes* var.; M. Oct. Van der Cruyssen, for *Azalea M. E. Chantrier*; M. E. Bedinghous, for *Tremandra verticillata*, and (*par acclamation*) for *Yucca pendula* (*recurva*) medio aurea picta; M. J. Hye (*par acclamation* and *avec félicitations de Jury*), for *Leclio-Cattleya callistoglossa* (*Leclio-purpurata* × *Cattleya gigas*); and to M. H. Millet, for *Tristonia robusta* vana.

Cultural Certificates were awarded as follows:—to M. L. De Smet-Duvivier, for *Ameocheilus Dawsoniana*; M. G. De Saelger, for *Veitchia capensis*; MM. Durie frères, for *Davallia dissecta*; and M. E. Bedinghous (*par acclamation*), for *Aecia verticillata*. A Botanical Certificate fell to M. A. Van Inshout, for *Trichophyllum prodigiosum*. Honourable Mention was awarded to Comte Joseph de Henningpo, for *Clivia miniata* var.; and to M. Oct. Van der Cruyssen, for *Azalea Moinore* de Madame Oct. Van der Cruyssen.

ROYAL HORTICULTURAL Scientific Committee.

APRIL 13.—Present: Dr. M. T. Masters in the chair; Mr. McLaughlin, Rev. W. Wilks, and Rev. G. Henslow, Hon. Sec. *Nishomus* raised from *Sporis*.—With reference to this subject, the following communication was received from Dr. D. H. Scott:—"Mr. Massee, of Kew, has referred me to what seems to be a thoroughly successful solution of the problem,

how to raise Mushrooms from spores. Two French authors, Costantin and Mitrachot, have raised fine varieties true from spores, carrying on their cultures in sterilised food solutions, and subsequently on sterilised manure. The whole development is said to take from six to seven months. ("Comptes Rendus," vols. 117 and 118.)

"*Riveriana, Cere. Soc.*" With reference to this, discussed at the last meeting, Dr. Masters remarked that Mustard as powder, or dug in green, had proved to be effective in destroying this pest.

"*Daffodil with White Corona.*"—Dr. Masters exhibited a blossom having this peculiarity, which occurs also on Cyclamen, Primroses. The structure of the fibro-vascular cords is peculiar in the Daffodil in having its elements reversed in position from those of the perianth itself. It was received from Mr. Dick, of the firm of Messrs. Cooper, Tabor & Co., *Armenia Palace*. He also showed specimens of this flower from the Riviera, and also the Greek form with rounded sepals. Several of the former were becoming double, just as is the case in South of France. Dr. Masters observed that the wild Anemone, *A. nemorosum*, had become double in his garden during years' growth. Mr. Hemlow added that the same had occurred with him; specimens originally single, received ten years ago from woods in Wiltshire, were now semi-double.

"*Larva of Bibio.*" Mr. McLachlan observed that an error occurred in the statement about propagating soil containing the larva of daddy-long-legs, in the report of the meeting on March 9th. It should have been that of a species of *Bibio*.

"*Tulip leaves Dissected.*"—Mr. Thos. Waincock of Polegate, Sussex, sent specimens of leaves showing dissection. They were forwarded to Kew for examination.

"*Chrysanthemum crinale.*"—Mr. De launay sent specimens of the original form of this plant exhibiting different shades of colour as well as a cross between it and the garden form. The latter was of a deep crimson tint.

"*Daphniphyllum*."—Rev. C. W. Dod sent two specimens, consisting of young plants, of which the stalks were fused for the entire length from the base to the very top of the stem. He observes that in one case "the union was by a superficial membrane only; but in the other the combination was complete, the joint space being hollow at the base, without any visible joining."

"*Burkhardtia.*"—Mr. Dicks brought specimens of this unclimber, which is common in the woods and hedges and open hills about Croydon, the tubers being much eaten by children at that neighbourhood. He remarked that two children, of the ages two and ten, had lately died, apparently poisoned by the leaves of some wild plant, but its nature could not be discovered.

Fruit Committee.

APRIL 21.—The first meeting for the season of the Fruit and Vegetable Committee at Chiswick was held on Wednesday last. F. Crowley, Esq., chairman, was present; as also Messrs. W. Farr, J. Willard, J. Smith, W. Pope, C. Herrin, G. Reynolds, G. Wythes, J. Wright, A. F. Barron, G. Burgard, A. Deau, H. Balderson, and J. A. Laing.

The chief objects before them were the forced French Beans, of which a large collection grown in their large pits was forced in one of the houses. The Committee inspected some two dozen stocks, several being duplicates. All were sown on January 15. The earliest to furnish p's, short, fleshy and very green, was the German var., Empress William, which were fit to gather on April 11. It is not, however, so bushy and free cropping as a variety as some others. The last of these all being ready on or about April 25, were Osborne's, possibly so valuable for early work, No Plus Ultra, probably the best all-round and very prolific. Wythes' Improved Mohawk, product of a cross between the old Mohawk and Canadian Wonder, yields the dwarf Butter Beans. These few varieties each obtained three marks as former Beans, Cranfield Wonder, some of Smythe's Hybrids and others had been tried fairly well, but did not seem to be so useful for pot culture as were the varieties named. A desire was expressed that the selected varieties, especially the little known Empress William, be grown outdoors during the winter. A trial of a few first early Radishes in a frame from a sowing done expectly five weeks previously showed Vilmoren's Extra Early to be much the earliest. Olive shaped White, and Scarlet, each of these being quite a week in advance of any others. These were unanimously awarded F.C.C.'s for exceeding earliness as well as excellence. They are much earlier than the well-known French Breakfast. The scarlet variety known as Leafless, really a misnomer, because it has leaves, though very short ones, is less useful than these named. The Committee, afterwards viewed some seedling Rhubarbs, but found nothing of special merit in them. There seems to be nothing superior to Hawker's Champagne and Victoria.

CHESTERFIELD CHRYSANTHEMUM SOCIETY'S SPRING SHOW.

APRIL 19.—The Exhibition of Spring Flowers in connection with the Chrysanthemum Society of Chesterfield took place on Easter Monday, in the gardens of Tupton House, by permission of Mrs. Markham, who is President for the year, and announced in the present issue. In having President the gardens. The Society has been fortunate in having Presidents who are not only possessors of excellent gardens, but who are in sympathy with the objects of the Committee, namely, the fostering among the toiling masses a love for plants and flowers. Thus, in 1897, Tupton Grove, with its

Rock Garden and Daffodils, was the place visited. Last year Ashgate Gardens, on the other side of the town, was the place of meeting; and now this year Tupton House, well known as the old home of George Stephenson, was the place of exhibition. In going through the houses with Mr. Grimes, the gardener, we were pleased to see indications of fine crops of Grapes, while in the Apple and Fig houses there was also plenty of fruit. Amongst the Peach trees in the houses, attention was drawn to one of Royal George, planted by Stephenson, in 1846, which is carrying a promising crop of fruit. More than sixteen dozens of good fruit were taken from the retreat tree last year.

In the exhibition tent, Messrs. PEARSON & SONS of Clifton, Nottingham, set up 100 bunches of Narcissus. R. F. MILLS, Esq., of Tupton Grove (gr. Mr. Bloxham), also set up an excellent lot grown in a far less favoured locality than the Clifton blooms, and he was awarded a 1st prize; a similar prize for 12 vars. of hardy flowers, and premier honours for Chimeras. From the gardens of A. BARKES, Esq., of Ashgate (gr. Mr. Nelson), came the best lots of Hyacinths, Magnolias, Delytras, Orchids, and bunches of stove and greenhouse flowers.

The 1st prizes for Delytras, Ferns, French Chimeras, and specimen A-clea, were awarded to Mr. Austin, gr. to M. BERT, Esq., of Chesterfield; while Mr. Polkingborne, gr. to Mrs. E. BARKES, showed a finely flowered specimen greenhouse Rhododendron. C. E. CLYTON, Esq., of Thornfield (gr. Mr. Hornsby), had a fine lot of flowering, and foliage plants. Mrs. BURTON, of Rose Hill (gr. Mr. Money), was 1st for a cheerful looking group of smaller size. A very attractive group, not for competition, came from the gardens of T. P. WOOD, Esq., of Brimbling House (gr. Mr. Clements), consisting of many lovely specimens with Japanese notes intermixed, and edged with Delytra, spectabilis and Astilbe japonica. The hon. sec., Mr. NEESON, also staged a group, not for competition, in which some fine specimens of the old Spirea Arneuse were very conspicuous, proving its amenability to pot culture. Mr. BERT, of Tupton Manor House, brought an interesting collection of Hardy Ferns; while another amateur, Mr. M. MASTERTON, of Chesterfield, staged a creditable miscellaneous collection of plants.

THE WEATHER.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Days above and Days below the signifying the number of twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

Table with columns: TEMPERATURE, RAINFALL, BRIGHT SUN., and a detailed table of accumulated temperature and rainfall data for various districts.

The districts indicated by number in the first column are the following:— 0, Scotland N. Principal Wheat-producing Districts... 1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. Principal Grain, etc., Districts... 6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; *Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending April 17, is furnished from the Meteorological Office:—

"The weather continued in a very unsteady condition generally. Rain fell almost daily in the west and north-west, and very frequently elsewhere. Thunder and lightning occurred in many parts of the kingdom during the middle or the latter end of the week."

"The temperature just equalled the mean in most districts but was slightly above it in 'England, S.,' and below it in 'Scotland, N. and W.,' 'England, N.W.,' and 'Ireland, N.' The highest of the maxima were registered, as a rule, on the 14th, and ranged from 63° in 'England, E.,' and 62° in the 'Midland Counties,' to 56° in 'England, S.W.,' and 'Scotland, W.,' and to 55° in 'Scotland, N.' The lowest of the minima, which were recorded on the 11th, varied from 55° in the 'Midland Counties,' and 54° in 'Scotland, E. and W.,' and 'England, E.,' to 50° in 'Ireland, S.,' and 37° in the 'Channel Islands.'"

"The rainfall exceeded the mean in all districts. In the south and east of England, the excess was slight, but in all other localities it was very large, the fall in many cases being considerably more than twice as much as the normal."

"The bright sunshine was less than the mean in all districts except 'Scotland, E.' The percentages of the possible duration ranged from 34 in 'England, E.,' and 53 in 'Scotland, E.,' to 25 in 'Scotland, N. and W.,' and 'England, S.W.,' and 24 in 'England, N.W.,' and to 23 in 'Scotland, W.'"

MARKETS.

COVENT GARDEN, APRIL 22.

[We cannot accept any responsibility for the submitted reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal dealers, who refer to us as the normal. The prices for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Etc.]

Table listing market prices for various flowers and plants, including Anemones, Daffodils, and various bulbs, with prices per dozen or bunch.

Table listing market prices for various plants and vegetables, including Adiantum, Aspidistra, and various ferns, with prices per dozen or bunch.

Table listing market prices for various vegetables, including Artichokes, Beans, and various greens, with prices per dozen or bunch.

FRUIT.—AVERAGE WHOLESALE PRICES.

Fruit, s. d. s. d.		Peaches, per doz., s. d. s. d.	
Apples, Tasmania, per case, selected samples	10 6-11 0	— Melrose, per doz., ...	12 0 —
— per case, of dietary samples	7 6-8 6	— Scotch, per doz., ...	9 0 —

Native, Cob, per 100 lb., ...	70 0-72 6		

FLOWERS IN SEASON.—Some flowers of Mr. WILLIAM BULL'S strain of Cinerarias which have been sent for our inspection, are remarkable for the velvety richness of their colours, especially the selfs of various shades of purple; the clear, broad margins of others, and the size and substance of most of them. If the flowers are plentifully produced on the plants, nothing is left to be desired.

NOTICES TO CORRESPONDENTS.

ANNUALS FOR SOUTH AUSTRALIA: *Australia.* Any of the annuals indigenous to Australia (Swan River District), very beautiful ones; those from California, Mexico, and the Cape of Good Hope. Those which are tender here would do well out-of-doors, if you have sufficient water supply.

BEGONIAS: *F. Baker.* It is always an advantage to remove the flowers of plants you desire to make rapid progress; and this rule holds good of the tuberous Begonia. You might remove the female blooms only; or the stamens of both sexes, if you are not caring for the plants to make any show till they have increased in size.

CAMELLIAS: *H. J. McR.* Your Camellia leaves are disfigured by scalding. The leaves have become heated when wet with water. Give ventilation earlier upon bright mornings. Camellias sometimes require a slight shade.

CORRECTION: *National Aerials Society's Exhibition.* The 1st prize in the leading class for twelve show Auriculas was reported in error to have been taken by Mr. C. Phillips, Bracknell, Berks; whose collection was placed 2nd; and Mr. A. J. Sanders, Bookham Lodge, Cobham, who was announced as being 2nd, was awarded the 1st prize. Mr. Sanders is to be congratulated upon having attained to this coveted position. *The Reporter.*

CUCUMBERS: *H. S. C.* Probably owing to check to growth caused by earthworms in the soil, examine the roots, and ascertain if there are wart like excrescences upon any of them. If this is found to be the case, a fresh start had better be made with soil free from the pest.

DISEASED TULIPS: *G. T. L.* Neither the nature nor the nature of the soil have had influence in producing or in accelerating the spread of the disease. The bulbs were affected with a fungus, *Peziza caricivora*, the sclerotia or grains of which existed within the substance of the bulbs when you bought them. So long as the bulb remained quiescent, the sclerotia were also inactive, but as soon as it began to grow the latter began also to grow, eventually causing the destruction of the tissues. Possibly the naked eye would have discovered minute, black, projecting spots on the outside of the bulbs when in the dry or dormant state. For figure and description, see p. 361 of *Gardener's Chronicle* for September 23, 1888.

FIG BRANCHES DISEASED: *R. D.* The branches are attacked by a fungus called *Phoma cinerascens*, Saccardo. This fungus is known for its injurious effects on fig trees in Italy and France. The only means of saving the tree is to cut out and burn all diseased branches. If the entire tree could be sprayed with Bordeaux Mixture, it would prevent further inoculation from the mature spores of the fungus, which are abundant in the examples sent. *E. Massie.*

GETTING A LIVELIHOOD: *Star.* There are many persons now getting a good living by growing Tomatoes, Grapes, &c., and why should not you? The neighbourhood of a large town offers advantages, but it has the drawback of high rents for land and house. We would rather not further advise you.

GRAPES: *St. A.* The fruits are affected with the "spot" fungus, *Gleosporium loticolor*. Cut out and burn forthwith all affected berries, dust the Vines and bunches with flowers-of-sulphur, and paint the hot-water pipes with the same, mixed in lime-wash. You must use sulphur freely in the dressing you apply to the vines another year, or make use of the Bordeaux Mixture.

INSECT: *W. G. A.* weevil; very destructive. Trap them with slices of Carrot or Potato, and go round the house at night.

LAWN GRASSES: *W. B.* If the grasses die out in four months, there must be something in the situation or in the soil injurious to plant life. It is not the presence of weeds, these doing good by bringing up soil from below the surface, and by their borrows aerating the soil and giving egress to the water to lower depths. Is the lawn much shadowed by trees or buildings? If you will answer this question, we shall be enabled to give you the names of grasses best suited to the situation.

LORD ROSEBERY POTATO: *G. S.* We are unable to find in any list of varieties a Potato of this name.

NAME OF FRUIT: *W. J. B.* Winter Queening.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—1, *H. L.* Viola odorata.—*J. B.* 1, *Oxycoccus luteo-purpureus*; 2, *Oryzopsis nutans*.—*S. Cleave.* The large flower, *Lolium purpurata*, grow in intermediate house lightly shaded; *Cyperidium barbatum* grow warm and tolerably shade. Two short bulbs, *Stanbopaea* species, grow in baskets suspended. The yellowish bulb, *Oncidium spheacelatum*. Both the last named grow in warm greenhouse.—*D. M. P. A.* 1, *Forsythia suspensa*; 2, *Griselinia littoralis*, rarely seen in flower.—*G. D.* Waterford, 1, *Polygala Dalmaniana*; 2, *Tiarella cordifolia*; 3, *Potentilla fruticosa*; 4, *Ouychium laudatum*; 5, *Pteris serrulata*; 6, *Asplenium bulbiferum*; 7, *Cyrtanthum falcatum*.—*R. C.* Arenaria balaenica.—*W. G.* *Populus balsamifera*, the Balsam Poplar.—*W.* *Cytisus praecox*.—*H. E. G.* 1, *Spiraea prunifolia*, double-flowered var.; 2, *Ribes aureum*; 3, looks like *Ekechordia grandiflora*, but the flowers are not expanded.—*R. R.* 1, *Pulmonaria officinalis*; 2, *Polygala Dalmaniana*; 3, *Cupressus Lawsoniana* var.; 4, *Myrica Gale*; 5, *Polygonum cuspidatum*; 6, *Spiraea Thunbergii*.—*W. T.* *Kerria japonica*.—*Foreman.* *Swainsonia galifolia*.

PEACHES: *A. Scott.* The fruits sent are affected by mildew. Apply flowers-of-sulphur, and remove and burn forth with the fruits showing any traces of mildew. If the trees are under glass, paint the hot-water pipes with whitewash and sulphur.

PEACH HOUSE AND APHIDES: *T. L.* You might use Nicobar's XL All Vaporiser and liquid, but do not fumigate with tobacco before the fruits are as large as filbert-nuts, and then only in a slight degree. Do not sacrifice the leaves because the insects may abound on them, but as soon as the flowers are set afford the trees a heavy syringing with clear water night and morning, and keep this up till the fruits begin to colour.

PEACH ROOTS: *G. B.* The roots are healthy. Very likely indeed the gas has done the mischief.

PEACH TREE SHOOT: *Wootton.* The leaves are affected by the common Peach blister caused by a fungus known as *Ascomyces deformans*. It is thought by some observers that the cells of the leaves are first ruptured by an aphid or by spring frosts, and that afterwards the fungus appears. What is probably the more correct view is that of De Bary, who has found the fungus in an early stage as living inside the leaf amongst the cells, and at length only emerging to perfect itself upon the exterior. You might spray the leaves with a copper solution, or the Bordeaux Mixture. The fungus was figured in *Gardener's Chronicle* for July 31, 1895, p. 137, and many times subsequently.

PETROLEUM AS A DRESSING FOR KILLING INSECTS ON PLANTS: *H. Ward.* A safe quantity to use is 1 wineglassful to 3 gallons of water. The water used should be soapy, such as that used in washing clothes, with which the oil more readily amalgamates than with water only. The solution must be kept well stirred whilst being used, the oil otherwise coming to the surface.

PLANT ANALYSES: *C. H. C.* Several have been given recently in these pages, viz., Cyclamen, Carnation, Pine-apple, Cherries, &c. A small work by Dr. A.

B. Griffiths on the Constituents of Plants was published a short time since by G. Bell & Sons, 4, York Street, Covent Garden.

PROPAGATING-HOUSE: *H. Ward.* The bed or beds for propagating purposes may occupy a central position, or they may be built along the front or end walls of a house; but not against the back wall if it be a lean-to, unless it be a tall case to be used for tall plants, or for grafting purposes. A bed may be 1 foot deep measuring to the floor of 14, or 21 feet to the floor of the house. It should be provided with an oaken or stone sill, rounded on the outer edge, but flat on the top. The brick wall enclosing the hot-water pipes may be of 14 or 9-inch work, provided with a few small outlets, fitted with wooden or metal doors. The pipes may number five or six, of 1½-inch diameter, and should not approach the floor of the bed nearer than 1 foot. It is well to have independent flow and return pipes connected with the set of pipes in each section; the connecting pipes being furnished with clapper or screw valves for regulating the flow of water. Some of the sections had better not be fitted with frames, as not all kinds of plants strike well in air-tight frames. Top heat should be afforded in suitable amount, by means of hot-water pipes placed against the walls of the bed, and close to the wall-plates of the house if it be one without side-lights; and some top heat can be obtained by opening the small doors in the walls of the bed, a practice which is always advisable in cold weather. Too much light in a propagating-house is, for obvious reasons, not desirable; and some point to the north wall, and to be as open it should run north-by-south, and the two ends should be of brickwork. What is wanted is subdued light without the necessity of using shading materials too frequently.

SEEDLINGS: *Iresine.* Your seedling Iresine, *Mesembryanthemum*, &c., have "damped off." This is a gardener's expression for the death of young plants owing generally to the soil being too moist for the delicate young roots, hence their decay, and the consequent growth of fungous mould. As you say you have kept the soil rather dry, it may be the result of the soil containing too much manure. Without intimately knowing the conditions under which they are cultivated, we cannot say positively.

VINES: *G. M.* Your Vine is affected with Downy Mildew. See answer to "W. H." in our last issue; also *Gardener's Chronicle* for July 21, 1894, p. 75, where the fungus is figured, and remedial measures described. It may not be necessary to cut the Vine out; follow directions given to "H. J." & "G. B." After close examination of your further specimens, we find there is no fungoid disease present. The wretched appearance of the shoots is therefore due to some cause affecting the root—or, at any rate, some part of the plant which has not been submitted to us. It is necessary to examine the culture upon the spot in such a case. The Apple-buds appear to have been attacked by birds, or possibly frost.—*T. L.* We take it that you know nothing about the cultivation of the Vine. The viney was started with too much heat by night and day, and as a consequence the foliage is weak and thin, and liable to be affected by moulds of various kinds. If no bunches have appeared, there is no probability, judging from the size of the leaves sent, that any will show this season. We would advise you to purchase and read attentively some Manual on Vine culture.

WALNUT TREE: *J. S.* There will be about 15 cubic feet in the butt, worth if quite sound, and 1 tree was a pollard, perhaps 50 per cubic foot. If it has a good figure it will make handsome veneer, gunstocks, furniture, &c.

WHITE MARBLED NETL ROSE: *P. & Sons.* The variety is similar to one that has been exhibited at the Drill Hall on several recent occasions, and like it, is not pure white, though decidedly pale-coloured. Yours is a good bloom, and could be used amongst white flowers, if arranged judiciously.

Gardeners' Chronicle.

SATURDAY, MAY 1, 1897.

KEW.

THE brave show of Daffodils and Hyacinths, the glowing colours of the show-house, on which we have lately had occasion to comment, attract the populace, and no doubt effect a worthy purpose. These are things, however, that can be enjoyed elsewhere, whilst there are many other things that cannot be seen save at Kew. It is not the flower-beds that give Kew its pre-eminence. It is not the clouds of Snowdrops, nor the wavy sheen of Bluebells that render Kew so important an auxiliary to the development of our colonies, so serviceable to our home gardens and plantations, or so important as a scientific centre; it is the richness and interest of its botanical contents. On these we now propose to make some comment.

Beginning with the propagating pits, where only the privileged can get behind the scenes, batches of seedlings of such plants as *Myrmecodia* and *Hydnophytum* as fat as Turnips, may be seen, strange plants, swelling out at the base into fleshy tubers, hollow even here, but in their native countries channelled with innumerable tunnels, the resorts of countless multitudes of ants. Woe to the curious collector who puts his hand on such a shirt of Nessus. Now-a-days imagination comes to the aid of research, and so it is imagined rather than proved, that there is a sort of give-and-take arrangement between the ants and the plants, and that by virtue of such "symbiosis" both are benefited. It may be so, but at any rate in the pits at Kew, there is no obvious relationship to be seen between the little hollow tubers and the ants. Perhaps the Kew ants are not of the right breed.

Here also are *Nepenthes Pervillei*, the Seychelles Pitcher-plant, with crimson pitchers; an extraordinary *Dioscorea* from Sierra Leone with stout spine-bearing roots emerging from a large tuber, for all the world as if meant to protect it from burrowing thieves of the rat order. This plant is exciting much interest among the botanists, as also is a *Moraea* from the Cape, which has roots of similar character, forming a cage as of barbed wire, about the clusters of corms. Here also are new Palms, new Ferns, a new *Jupanea* called *Iringii* from New Guinea, and not unlike *J. Sultanii* from the other side of the African continent; *Dischidias* of sorts growing vigorously, and developing podgy pitcher-like leaves; and baby hybrids of *Disa*, *Streptocarpus*, and *Conandron*, with other still more remarkable crosses, to be heard of later on. A small tank contains young plants of three distinct sorts of *Victoria Regia*, one of which may possibly be a new species; and in a tub of water grows a *Crinum* with long, riband-like submerged leaves, more like a *Vallisneria*, than a *Crinum*. This strange plant was discovered in the Niger territories by Sir John Kirk, and brought to Kew two years ago; it has large pink flowers, which, in the

distance, look like *Nymphaeas* floating on the water. A *Crassula* with the habit of an Aloe; large paus of *Stapelia gigantea* growing like *Cactuses* in a hot, moist house; a pair of *Welwitschias* raised from seeds sent to Kew seventeen years ago, now with long leaves 2 inches wide; new Aloes, new Agaves, new *Cacti*, most of them caviare to the general cultivator, but of exceeding interest to the specialist. A variegated Agave from India, a golden *Furcraea* from somewhere else, an Aloe of extraordinary habit from the Hadramant, and another, mottled like a python, from Somaliland. These, and many more uncommon plants, are to be seen in those pits. Among *Orchids* *Eulophiella* grows like a Leek, as also do *Moorea irrorata*, *Bulbophyllum Ericsonii*, with many other *Bulbophyllums* and *Cirrhopetalums*. *C. robustum* had just developed two large umbels of its enormous green and brown flowers. An odd-looking *Eulophia* from South Arabia, and a batch of fresh arrivals from Sierra Leone, are of the kind that would delight students of the adaptability of plants.

In the house devoted to nursing Cape plants are numerous *Disas*, *Satyriums*, *Holothrix*, and other genera of *Orchids*; *Aemone Fannini*, and a distinct-looking *Ranunculus* from Natal, all of which are attractive; whilst on the roof, in full flower, is a plant, three years old, of the *Fride* of California—*Lathyrus splendens*, with flowers like Sweet Peas, coloured rich scarlet. The queer little *Rosa berberifolia* is also bearing several yellow *Cistus*-like flowers in the same house. An extraordinary *Sansevieria*, with long, thick leaves, like whip stocks, a recent introduction from Nile-land, and said to be a valuable fibre-plant, is represented by a large batch of plants, waiting for warm weather to be despatched to the colonies. New *Musas* from Java and other places are being worked up, as also are the new rubber plant, *Kickxia africana*, and the oil-yielding *Pentadesma butyracea*, both from West Tropical Africa.

The Succulent-house.—A big Agave *Botteri* has been in flower here, its spike like a gigantic *Eremurus*, the flowers yellow, with brown stamens. Close by is *A. Schottii*, a small species, with a slender spike of large bright yellow flowers. *Protea cynaroides*, 9 feet high, with three enormous flower-buds is on the point of opening. *Pitcairnia ferruginea* has a tall branched spike, 6 feet high, bearing numerous large rust-red and watery white flowers, more suggestive of *Puya* than *Pitcairnia*. Aloe *isoguis* is a remarkable hybrid raised by Mr. Cooper, of Redhill, who loves these plants as Baron Schroder loves *Orchids*. Numerous *Gasterias* form really beautiful flowering plants, as do a big specimen of *Epiphyllum Gaertneri*, bearing about a hundred flowers, many *Phyllocacti*, several species of *Bomarea*, the best of them being *B. frondea*; and *Aristea Ecklonis* with numerous spikes of rich blue flowers. The enormous *Iris* from Lord Howe's Island, the unique specimen of *Agave Morrisii* from Jamaica, the great *Cereus giganteus* and *Echinocactus Wislizenii* from Arizona, and the striking groups of African *Euphorbias* are always noteworthy features of this house.

Of the contents of the showhouse No. 4, we need say nothing, as it is only recently we alluded to them.

In the Ferneries one might spend many hours with profit, there being so many plants to interest one. The *Filix Ferns* are in fine condition, this collection being, no doubt, the finest in cultivation. *Gleichenias* are also very good here, and in the house where they are grown is a plant of an *Aspidium* from Ceylon, with the black clusters of sori borne only on the upper surface of the frond. It is the *A. monomium* of Hooker. A collection of *Marsileas*, many of them in fruit; magnificent examples of *Lycopodium*, including one named *Dalhousianaum*, with stems 4 feet long; large masses of *Selaginellas*, always well done at Kew, and some good specimens of *Platyterium* may be noted in these houses.

In the Cape-house there have been and are many beautiful bulbous plants in flower. *Geissorhizas*, *Babianas*, *Sparaxis*, *Lachenalias*, and the rosy-spathed *Richardia Ithmannii*, really tinted with rose all over. It is probable that we shall yet discover how to treat this plant so as to get the colour into the spathe that it undoubtedly has in Natal. *R. Elliotiana*, *R. Pentlandii*, and an unnamed one not unlike the last, are also unfolding large spathe. A gouty-stemmed plant, with fleshy cylindrical leaves, enclosed in a net-work of thin wiry-looking branched stalks, which on examination prove to be the old flower-stalks, is a singular inmate of this house. It is called *Cotyledon reticulata* (fig. 95, p. 252), and has lately arrived from the Cape.

The Begonia-house contains scores of beautiful *Begonias* in flower; and the air is quite aromatic with the odours of *Asarums*, of which there are some half-dozen species at Kew, their *Aristolochia*-like flowers being produced in a dense cushion-like mass just above the soil. Their cousins, the *Aristolochias*, are represented by examples of *A. Goldiana* with a purple and yellow flower the size of a coal-scuttle; *A. longifolia*, and *A. saccata*, this last with a large cluster of hairy flowers hanging about the base of the stem like a swarm of huge bees. *Fig* plants of *Tacca cristata* are in flower in the stove, and *Aglaonema costatum* appeals to the love of the beautiful, with its glossy green and creamy-yellow leaves, with numerous white finger-like spadices pushing up from among them.

In the Victoria-house, *Bismarckia nobilis* is magnificent, as also are the double *Coccoloba* and *Palm*; a large specimen *Melissia magnifica* bears scores of racemes of flowers; and the giant *Grammatophyllum speciosum*, which has never looked back since it was presented to Kew by Messrs. F. Sander & Co. four years ago. It may help to render this Jubilee year still more memorable by flowering, as it certainly looks vigorous enough. *Barringtonia samoensis*, with a stem 6 feet high, large, oblanceolate, bright green leaves, and long, drooping, whip-like racemes of large rosy *Myrtle*-like flowers, has also been an attraction in this house.

The Orchid houses.—Here there is a collection which surprises one when one sees the whole of it, and examines it here and there; such names, such pigmies, "such rubbish," many orchidists would say; but to the botanist as interesting, often more so, than the big *Cattleyas* and *Cypripediums*. Here is a list of some now or recently in flower: *Angraecum Germianum*, *Bulbophyllum harbigianum*, *Yuccidium tigrinum*, *C. aloifolium*, *Dendrobium Fockelii*, *D. Hildebrandii*, *D. dixanthum*, *Diacrium bicoloratum*, *Eulophiella Elisabethae*, *Epipedium Parkinsoniaum*, *Eriopis rufidolobum*, *Lycaste (Colax) jugosa*, *Lelia cinnabarina*, *Oncidium serratum*, *Odontoglossum Edwardi*, *O. cirrosum maximum*, *O. Reichmannii*, *Phaeoopsis Bosalli*, *P. tetraspis*, *P. Lueddemanniana*, *Physosiphon Moorei*, *Cypripedium nigratum*, *C. niveum*, *C. Chamberlainii*, *C. Victoria-Mariae*. Of course, there are the commoner things also, such as big pans of *Colochea cristata*, many long spikes of *Cymbidium Lovianum*, &c.

*Sarracenia*s growing in the porch of the *Orchid-house*, are always happy at Kew, and they are now pushing into the glory of bloom and new pitchers. *Helleborus*, *Cephalotus*, *Dionaea*, and *Darlingtonia* are nicely represented. The poppy-flowered *Drosera cistiflora* has gone.

The Palm house.—In this building is now in bloom *Napoleona imperialis*, bearing numerous crass-hat-like flowers; the *Clavijas* with their stems decked from top to bottom with spikes of orange yellow flowers, with the odour of Raspberry jam; *Tibouchina heteromala*, with erect racemes of rich blue-purple flowers; *Passiflora racemosa*; *Criminus*, of sorts; the rare *Nicolaia magnifica*, in bud; *Helleborus Biflorus*, with boat-shaped erect bracts; *Musa rosea*, a most beautiful plant, 19 feet high, with an erect spike,

bearing numerous bracts 8 inches by 4, and coloured bright lavender rose; Erythronchiton hypophyllanthos, a plant with a long, narrow, long stem, long leaves, and no flower stalk, the white flowers being attached singly or in pairs to the underside of the midrib of the leaf, about half-way up; Strelitzia Augusta, a big specimen, bearing many arm-like spikes of large white and blue flowers; Coffea arabica, and the supposed hybrid called Masagopipe, both of them bearing crops of ripe Cherry-like fruit; Macaranga, with enormous flame-like leaves, and clusters of small flowers; Brownsea's sorts, and Saraca indica. These are all, or were recently, in flower. In this house, too, is a good specimen of Wallichia densiflora, of which we received in due season a representation on a Christmas-card, from Mr. F. Im Thurn. Fig. 96, on p. 283, shows the Palm in question flowering in Mr. Im Thurn's garden in British Guiana. Palms and Cycads are, of course, the great features of this fine house.

The Temperate-house.—Here Rhododendron Griffithi, R. arboreum, R. ciliatum, R. kewense, R. serrylifolium, R. glaucum, and R. racemosum are finely in flower. Ranunculus grandifolius is flowering nicely.

The new wing to this fine house is now in the gardener's hands, and is likely to be made a worthy addition to the gardens under glass at Kew.

Of the Arboretum, the Panetum, the Bamboo Garden, the Rhododendron Dell, the Rockery, we cannot speak now. Stachyurus precox (fig. 97, p. 285), by no means a recent introduction, but which is still little known, flowered in the arboretum early in spring, before the leaves were expanded. Under glass both expand about the same time. Clearly, Kew cannot be seen in a day!

ORCHID NOTES AND GLEANINGS.

ORCHIDS AT HAREFIELD HALL, WILMSLOW.

The new range of Orchid-houses which Elijah Ashworth, Esq., has built to provide space for his large collection of Orchids, has had good effect on the plants; many of the valuable and rare ones, which the lofty, old-fashioned old houses did not suit, are greatly improved. The new houses are connected with each other by a long one which abuts on them at one end, thus affording shelter, and making it easy to secure an even temperature. In this long house a fine collection of all the best varieties of white and coloured *Laelia anceps* was remarked overhead, which must have made a fine display when the plants were in bloom. Here, too, and in the adjoining vicerias, was found a large collection of the showier *Dendrobies*, some examples of which have been frequently observed at the Royal Horticultural Society's meetings, and notably the immense specimen of *D. nobile nobiliss* for which Mr. Ashworth was awarded a Silver Medal.

In the first division of the range above noted are the smaller crosses of *Cypripedium*, as well as some plants of rare species, among which were six *Cypripedium bellatulum album*, three of which were showing flower-buds, a number of thriving crosses of *C. Charlesworthii*, out of which some good novelties should be seen; *C. × Olenus* and *C. × Leysonianum* in flower and bud, and *C. × Germanianum* and others in flower.

The next division of the range is the smaller Cattleya-house, containing the collection of varieties of *Cattleya Dowiana*, and some of the best of the varieties of the *C. labiata* class, such as *C. Mendeli alba* or *Blundi*, of which there are several; *C. Trianae* Normanii, and others.

In the third house was a fine group of freshly-imported *Cattleya Percivaliana*, having a distinct habit of growth; and a quantity of *Dendrobium Phalaenopsis*, among which were *D. Phalaenopsis hololeuca*, perhaps the only really pure white variety which has yet flowered. At the end of the house is a newly-constructed frame for the raising of seedling Orchids; and in the same house was a fine lot of *Cypripedium curvatum* Wallisi and *C. Rothschildianum*, plants of the latter being in flower.

Then follow several more houses in which were *Cattleyas* and *Laelias* chiefly. In these the varieties of *Cattleya Trianae*, now nearly over, have been grand, and two or three of them have induced visitors to come from long distances to see the plants. At the present season the display consists principally of *Cattleya Schroderae*, one of the best formed and most sweetly scented of all the varieties of *C. labiata*.

The plants of *Laelia purpurata* are well furnished with flower sheaths, and among them are the fine white form, the nearest to an albino yet produced by this species, and which is unique; and *L. purpurata* *Ashworthiana*, which is equally distinct in other directions.

Plants that were noted in flower in the intermediate-houses, were good examples of the true *Dendrobium nobile nobiliss*, and other varieties; some very fine *D. × splendidissimum grandiflorum*, *Spatuloglottis plicata*, *S. Kimballiana*; some fine specimens of *Miltonia Phalaenopsis*, *Platys × Cook-*

album, *D. Brymerianum*, *D. Hildebrandi*, *D. × Sybil*, *D. × Juno*, *D. × Owenianum*, *D. × melanodiscum*, *D. × The Pearl*, *D. fimbriatum oculatum*, and the pretty white and violet *Epidendrum Eadresii*.

Traversing the Peach-houses, which, like the vinerias, are in excellent order, and made available by Mr. Holbrook, the gardener, for resting Orchids on occasion, we came to the lofty old houses, which being built for ornament, are suitable for *Palms*, *Ferns*, and foliage-plants, but not for Orchids. In the first one entered were large plants of the stronger-growing species of *Cypripedium*, and a few of *Phalaenopsis*. In flower were *Cypripedium × Lathamianum*, *C. × Bartlettii*, *C. × Mearesianum*, *C. × Sedeni*, *C. × caribolea*, *C. × Adonis*, *C. lirsutissimum*, *C. caribatum Warneri*, *C. Phalaenopsis Schilleriana*, and *Cymbidium eburneum*. In other lofty houses were *Vandas* and other tall-growing species of *Orchids*, and several well-flowered plants of *Angreicum sesquipedale*. *J. O.B.*

FIG. 95.—COTYLEDON RETICULATA, KEW. (SEE P. 281.)

soni, a yellow and white form of *P. Sanderianus*, and *Cattleya Lawrenceana*; a fine variety of the white, rose-tipped *Chysis Linningshii*; a pretty white *Cattleya Trianae*, with a slight tinge of lilac on the lip; *C. × Hardyana*, and the curious hybrid *Laelio-Cattleya × Pittiana*, illustrated in the *Gardeners' Chronicle*, March 3, 1894, p. 265.

In the cool-houses the showier *Mastodallias* were beginning to expand their blossoms. The varieties of *M. Chimera* showing well, the *M. Wuiiana* already in flower being the darkest in colour. Here, too, are *Sophranitis grandiflora*, *Ada aurantiaca*, *Odontoglossum Rossii majus*, and *O. Cervantesii*, *O. crispum*, *O. triumphans*, *O. cirrosum*, and several hybrids of the *O. Andersonianum* type, two of them with peculiar features. In another house numbers of fine *Dendrobiums* in bloom were remarked, one hybrid, probably of *D. nobile nobiliss*, being very remarkable. Other species and varieties in bloom were *D. Finlayianum*, and one or two of the white *D. F. Ashworthianum*, *D. nobile nobiliss*, *D. n. Victorae*, *D. n. Wrigley's* var., and *D. n. Ashworthianum*, all good and distinct; *D. × Aspasia*, *D. Wardianum*

VANDA TERES.

This Orchid is now to be seen in superb character at Gonnorsbury Park. Mr. Reynolds has it in an elevated position on the west end of the stove-house, in which it is grown, near the glass, in a large box. There is a considerable number of plants planted out, the row nearest the glass being about a foot from it; then comes a passage round to the front of the house, and on the inner side of it a line of twelve more in 2½-sized pots, standing upon the brickwork which surrounds the raised bed in the centre. The plants have made a free growth, and are now blooming abundantly, for there are fifty-four spikes of blossoms upon the twelve plants in pots, and a considerable number upon those planted out, especially upon the sizes nearest the glass. The plants are occasionally dewed over with a fine spray, and the hot moisture of the house keeps them in admirable condition. The late Mr. B. S. Williams once wrote of *Vanda teres* that it is a "slightly-blooming species," but shyness is hardly a characteristic of those under Mr. Reynolds' care at Gonnorsbury Park, as they are decidedly floriferous. *R. D.*

DISA SAGITTALIS.

A few years ago *Disa uniflora*, commonly called *D. grandiflora*, was considered the only species amenable to cultivation, and it was not an uncommon occurrence that many persons failed to keep the plant alive. Since the introduction of *D. tripetaloides* and *D. racemosa*, and the production of a number of showy crosses between them and *D. grandiflora*, we have a large number of handsome, easily managed, varieties, to warrant a greenhouse being set apart for them. There is still much to be done to extend the culture of these plants, for, as proved by the handsome *Disa pulchra*, flowered by the Honble. Walter Rothschild, and figured in the *Gardeners' Chronicle*,

The flower is the size of that of an ordinary *O. crispum*, and well formed in all its parts. The dorsal sepal is broader than the inferior ones, and the others favour the ovate-acuminate form; the basal portion is like *O. crispum* in its ground colour, and is furnished with a number of minute Indian red spots; two-thirds of the segments towards the extremity have the pale-lemon ground-colour of *O. sceptum*, one of the parents, with from two to four large sepia-coloured blotches. The petals are ovate, ensiform at the extremity; the white in the lower portion of their limbs is strongly suggestive of *O. crispum*; and the Indian red spots at this point are numerous. The upper portion is like the other limbs, the blotches being less in

mation that the plant was purchased some years ago as *Houilletia* from Chiriqui, and that it had not yet been identified. It is an ally of *Acineta*, and the plant resembles those of that genus, and the inflorescence is a stout pendulous raceme, produced after the manner of *Acineta*. The expanded flower is nearly 2 inches across; the sepals and petals of a pale Peach-blossom tint, densely speckled with lilac; the enurious lip, which has a stalked front-lobe, which possibly suggested *Houilletia*, has the side-lobes erect, and white in colour; the front-lobe speckled with purple. It is one of those sufficiently showy species which, being uncommon, always attract attention. *J. O.E.*

FIG. 96.—WALLICHIA DENSIFLORA IN MR. IM THURN'S GARDEN, BRITISH GUIANA. (SEE P. 282.)

Dec. 26, 1896, p. 785, there are still finer species available for cultivation and for cross-breeding. An example of *Disa sagittalis*, with many spikes of white flowers, which have a few purple lines on them, is now in flower in Mr. E. Ashworth's collection, Harefield Hall, Wilmslow, Cheshire. *J. O.E.*

ODONTOGLOSSUM THOMPSONIANUM.

This beautiful form is a cross in which the traits of both the parents are clearly defined. It is the property of Wm. Thompson, Esq., Walton Grange, Stone (Mr. W. Stevens, gr.), and was exhibited at the meeting that inaugurated the founding of the Manchester Orchid Committee in the Memorial Hall, Manchester, the plant carrying eleven flowers, closely set together, forming quite a Hyacinth-like spike.

size, and more numerous, and there is a shade of white over the lemon-coloured ground. The lip in form is not contracted at all in the middle, and is more white in its lower lobe than any of the other limbs. An immense blotch of Indian-red is planted at the base of the calli, and on either side are spots of reddish colour. The base of the calli itself partakes of an orange ground, with red lines; the column is prominent, and stands convexly, yellowish-white at the back, with a crowd of glandular hairs around it up to the stigmatic surface. *J. Anderson.*

LACENA SPECTABILIS.

A fine inflorescence of eighteen flowers of this rare species is sent by Frau Ida Brandt, Brunnenhof, Riesbach, Zurich (gr., Mr. Schlecht), with the infer-

PRODUCTS OF THE CITRUS TRIBE IN SICILY.

REPORTING on the trade of Sicily, Mr. E. M. de Garston gives some interesting facts connected with the staple products, such as essence of Lemon and other produce of the Citrus family, the different trades dealing in these being of a very interesting character. The Lemon essence industry is a very important one in Sicily, where the abundance of raw material naturally renders the manufacture of the so-called oils of Lemon and Orange a very profitable undertaking; 37,911 kilos. of these essential oils were shipped during the year 1895, over 32,000 kilos. of which was taken by Great Britain.

Oil or essence of Lemon is obtained by pressing or bursting the oil-glands in the rind of the fruit, and this is done either by hand or by machinery; that obtained by the first process being by far the best in quality. In Palermo the essence is all pressed at night. The workmen are supplied with a certain quantity of rinds, divided into equal portions to each between so many gangs, each under the supervision of a foreman. Each man holds two sponges between the fingers of the left hand, and works the rind about in the best way to fracture the oil-vessels. This is caught in the sponges, which, when sufficiently charged with oil, are squeezed into an earthenware receiver; a considerable proportion of the product thus obtained consists of ordinary Lemon-juice left adhering to the rind, together with more or less of the Lemon pulp. This, however, being heavier than the essence, sinks to the bottom of the receptacle, and the essence remains on the top. As the first of these receivers becomes full, the workman blows the floating oil into the second jar through a species of channel formed in the side of the first, and when no more of the essential oil transferable by blowing, the remaining essence which may yet be floating in the original receiver is carefully absorbed with a sponge, and thence squeezed into the second receptacle, which only contains pure essence.

The remainder, namely, the essential oil which may still have been left in the rinds, is by some manufacturers extracted by distillation, and forms a second quality of essence. By others, again, it is expressed by subjecting the partially exhausted rinds to mechanical pressure in bags. To ascertain, however, if the obtainable essence has been thoroughly squeezed out by the original hand process, the rinds are tested by a foreman, who presses the supposed exhausted peel into the flame of a candle, when, if any combustion is visible, it shows that the presses have not done their work properly. The essence obtained by the foregoing process undergoes no further manipulation beyond being collected, and after careful filtration through filter paper it is ready for shipment in the usual coppers of 100, 50, 25, 12, 5, and 2 lb. each. When freshly expressed it has a delicious smell of the fruit, which is greatly injured by distillation.

From the leaves, flowers, and fruits of the several species and varieties of the Citrus genus a large variety of products is obtained. The blossoms in their natural state serve to flavour drinks and sweetmeats. When distilled they yield two very much esteemed products, namely, orange-flower-water and an essential oil known as Neroli. Moreover, when caudied, they form a delicious sweet, much in

vogue in some regions of Sicily. The orange-flower water is made of equal portions in weight of blossom and water, which yield on an average about one-fifth of the combined weight of water and flowers. Notwithstanding the abundance and excellent quality of the raw material, so to speak, still the best manufactories of Orange-flower-water are to be found outside Italy. As to candied sweetmeat concocted out of the blossoms, it is doubtless more wholesome as well as more palatable than many other productions of the confectioner's art. The flowers in the first place are selected with care, weighed, and immersed in cold water for twenty-four hours, after which they are dipped singly in cold water, re-washed in cold, and finally spread out on a linnen cloth or sheet to dry. When completely dry, they are laid out in low, wide dishes, each flower separate from its fellow, and are then sprinkled with double their weight in sugar, administered at intervals during a period of eight days or thereabouts. Moreover, during the same period the flowers should be frequently moved and kept in the shade; at the expiration of this time they are once more placed in the sun, whose rays dry them completely.

The raw juices of all the different varieties of the species of Citrus, except that of the Bergamot, are available for commerce; but the juice of the Lemon is the more highly prized, on account of the greater amount of acidity it contains. But the raw juice, "Agro-crudo," however rich in acid particles, can never vie in this respect with the same juice in a concentrated form with the "Agro-cotto," in which form it enjoys besides a great superiority over uncondensed juice in durability and in reduction of volume. This concentrated juice is prepared in the following manner. It is first of all clarified by being left to stand, then boiled in large cauldrons of tinned copper, one-third full, and the boiling liquid frequently stirred with an iron rod having its head wrapped in common canvas, or in rags which have thus to keep the bottom of the boiler clear of all sediment; those necessary additions to the boiling liquid which the constant evaporation of the aqueous particles renders expedient are supplied by smaller supplementary boilers in which the liquid is kept sufficiently hot to hinder any interruption in the ebullition of the juice contained in the large vessels. When the required density is obtained, a point which is easily ascertained through the medium of the citrometer, it is poured into vats to cool, and finally drawn off through ordinary funnels into casks.

The adulteration of the acid or juice is facilitated by the ready absorption of certain well-known and easily-obtainable substances, which increase the weight of the acid-juice when concentrated. The most commonly employed substances for the purpose of adulteration are tartaric acid, chloride of sodium, and sulphuric acid. The methods employed in Sicily in order to detect the cheat, if not so scientific and perhaps less accurate than these in use in England, are at least inexpensive, simple, and sufficiently effective. Citrate of lime, which seems to be the safest form in which the acid principle can be conveyed, and is the substance whence the citric acid is directly manufactured, is now prepared to some extent in Italy, although up to within the last quarter of a century this preliminary process was considered impracticable from a remunerative point of view. A very well known authority on the subject laments in forcible terms the remissness and ignorance of his countrymen in Sicily, which alone permits foreigners to reap that harvest which Italians neglect to gather and garner for themselves. The objections raised in bygone days, from the supposed impossibility of procuring at home a sufficient quantity of proper chalk, have been shown to be utterly mistaken with respect to the production of citrate of lime. Objections of a similar nature are now mooted with regard to the production of citric acid, and have been partly disproved already by the establishment of a British firm in Messina, which has undertaken successfully the manufacture of citric acid in conjunction with tartaric acid.

With regard to the essential oil industry in Sicily, it is said to be both widespread and prosperous,

Essence producers and exporters are numerous. The essential oils are derived from all varieties of the Citrus group, though they differ considerably in quality, that expressed from Bergamot being the best, and then follow the Lemon, Orange, and Citron, the relative value of the essences being in inverse order to that of the juices.

The mode of payment of the workmen engaged in expressing the essential oils is peculiar. Instead of being paid at a fixed rate per day or hour, or for the weight or number of rinds expressed, he is remunerated according to the amount of essence he succeeds in extracting out of a given weight of rinds.

It is stated that, though the bulk of the oil produced in, and exported from, Sicily is quite pure, yet it is sometimes adulterated with other essential oils, and sometimes with turpentine, or even with resins. The occurrence of these adulterations seems to have discredited and unsettled the market value, so that it became necessary, or at least expedient, in some cases to submit it to analytical test before exportation. Owing to these precautions, the character for genuineness of the Sicilian essential oils has been redeemed, or rather maintained. *John R. Jackson, Kee.*

A PARASITIC AGARIC.

A COMMUNICATION from the Pathologist's Branch of the Department of Agriculture, Melbourne, accompanied by specimens, dried, and also preserved in corrosive sublimate solution, and in solid paraffin, of a small form of *Hypophoma fasciculare*, which is so common here about old stumps, gives the following information. This Agaric is found at the roots of Raspberry-canec, and is causing a great deal of damage. The copious white mycelium or spawm soon destroys the roots. As the ground is generally well cultivated, I had some difficulty in finding the fructification, but in a somewhat neglected plantation I obtained it in abundance. This Agaric grows in dense tufts, and is of a greenish-yellow to golden-yellow colour, becoming reddish at the top of the pileus, which is usually from 1 to 2 inches in diameter. The gills soon become of an olive-green colour; the flesh throughout is yellow and intensely bitter. The spores, about 6 to 7 by 4 μ , are yellowish-brown under the microscope. The specimens received are much smaller than usual, but agree in all other points, even to the size of the spores above stated, being from Australian specimens. Generally the pileus does not exceed from one-quarter to three-quarters of an inch in diameter in its parasitic condition, but there is no room for doubt as to its being the old familiar species.

Hitherto this Agaric has been regarded as absolutely saprophytic, but there are evidently conditions under which it may become a destructive parasite. As it is so common with us, on old stumps everywhere, it will have to be watched for any exhibition of its parasitic proclivities. But little information has been given of its action in Australia, except that it attacks Raspberry-canec, and by means of a copious white spawm, destroys the roots. That it is becoming a real pest is evident from the attention of the Department having been directed to its action; but, as yet, it seems to confine its parasitism to the Raspberry.

We have no record of parasitism of this species in Europe, where it is extremely common. In the Australian colonies it is recorded for Victoria, South Australia, and Tasmania. Possibly the spawm originated from dead wood, or buried stumps, and impregnated the soil, but whatever the cause of this new development, it will have to be checked by attention to the soil, and the destruction of the pestiferous spawm, by exposure, the application of lime, and other fungicides. The fungus is regarded here as so thoroughly harmless that it may be found in profusion in almost any large garden, and never causes the least anxiety; but these facts will sound an alarm, so that in future a watchful eye will be kept upon the spreading of the spawm of *Hypophoma fasciculare*. *M. C. Cooke.*

SPRING GARDENING AT CLIVEDEN.

THE old reputation of Cliveden for spring gardening is being well maintained by the present owner, the Hon. W. W. Astor, and his gardener Mr. Waddis, who borders under the terrace and the large beds stretching away on the lawn being just at the present time very gay, and in a perfectly well-kept condition. The large flower-beds, which are raised somewhat above the lawn level, although on grass, have a high Box-edging which has during the past autumn been entirely replanted with fresh plants, and trimmed into regular shape. A second terrace has also been constructed below the original and well-known one, choice marble pillars and balustrading having been brought over from Italy and used in its formation, being in keeping and design in character with the surroundings. The Vandyke-shaped raised border under the upper terrace is gay with *Violas*, in which the varieties Blue King, Skylark, Souvenir, Cliveden Yellow, Mauve Queen, and Countess of Hopetoun are used, the sloping front being covered with *Aubrietia*, and the angles at the back filled in with Cloth of Gold *Viola*. All the beds on the lawn are now brilliant with *Tulips* in glowing colours rising from an undergrowth of *Violas*, about 25,000 of each being used. After the *Tulips* are over, the *Violas* fill up and carry the display on well into the summer. No summer bedding out is now practised, the spring-flowering subjects being allowed to remain until blooming is quite over; but this season it is intended to fill the beds with *Asters* in distinct colours for a late summer display. Four large beds are filled with White Lady *Viola* and *Artus Tulips*, and the same number of beds with Belle Alliance bright red *Tulips*, with a groundwork of Yellow Prince *Violas*. Others are planted with La Reine *Tulips*, white, tinged with rose, and a base of Souvenir *Viola* and Couronne Pourpre, dark crimson *Tulips*, and another yellow *Viola* unnamed. Each of these beds contains some 1500 *Tulips*, and as many *Violas*; while flowering in a series of beds arranged to form a large circle at a distant part of the lawn, 6000 Golden Prince *Tulips*, and Cloth of Gold *Violas* are very effective. A new herbaceous garden has recently been formed, which in time promises to become one of the features of the place, although the arrangement in conjunction with clipped shrubs in fantastic shapes would by some be thought out of place, and can scarcely be considered in keeping with the occupants of the herbaceous borders. *Viola*.

HARDY JAPANESE AND CHINESE VINES.

M. L. LINDET contributes to the *Comptes Rendus* for March 15 a paper on "Acclimatising Japanese and Chinese Vines at Damigny (Orne), and on the Wine yielded by them." He says that—"The Department of Orne is situated beyond the extreme limit of the wine-growing districts, and its climate has hitherto been considered as unsuitable for the culture of the Vine, and the ripening of the Grape. For a few years now, M. Caplat has succeeded in acclimatising at Damigny, near Alençon, certain varieties of the Vine, introduced from the cold, damp, and mountainous districts of China and Japan.

These Vines were discovered by Pere David, and some seeds were imported into France by M. Henri Degron. Sown for the first time by M. Caplat in 1852, they have since been so far propagated, that it has been possible to send cuttings of them into most of the Departments. The matter has been made the subject of study by Carriere and by V. Pulliat.

The Japanese and Chinese Vines cultivated at Damigny are of vigorous and powerful growth; the branches are lengthened; the petioles, generally various-red or violet in colour, are equally long, sometimes covered with hairs, shaded from red to yellow (varieties of V. Romaneti), sometimes covered with spines (Spiovitius Davidi); the leaves are sometimes cordiform (Précoce Caplat), sometimes bi-, tri-, and pentolobate, and sometimes even lacinate (V. Romaneti and V. Pagnucci); the bunches, from 8 to

12 inches long, are formed of rounded Grapes, rather far apart, and generally covered with a thin but firm skin, shining, pruinose, below which is a pulp almost always dark red, rarely rose-coloured.

One of the most interesting characteristics of some of these Vines is their earliness; this is found in a Japanese Vine, a seedling of *V. Coignetia* (Précoce Caplat), which at Damigny yielded ripe Grapes from the 15th to the 20th of September. This late was only a few days earlier than that of the maturity of other Vines grown in this district (*V. Romanet*, *V. Fagnucci*); *Spinovitis* does not ripen until later—from October 1 to 15; *Carrieri* is still later.

The trials of *Précoce Caplat*, made in Burgundy, Cher, Haute-Garonne, and other districts, tend to prove that this variety resists the common diseases of the Vine well.

M. Lindet publishes a table of analyses of wines made from the above Grape. "A mere glance," he says, "at these figures will show that the quantity of alcohol equals that in our weaker wines, but the quantity of extract, of acidity, of tartar, of tannin, and of ash, is twice as great as in ordinary wines; as to the colour, which is very clear and bright, it is of an intensity four or five times greater than is generally admitted in the wine trade.

"Analysis made in 1896 of wine from the *Précoce Caplat*, vitaged in 1895, shows, further, that these wines lose little by age, the difference in the composition consisting almost wholly of the deposit of a certain amount of tartar.

"It is easy to judge, from analysis of these wines, of the advantages they offer for trade purposes, and for making *vins de coupeur*, *dits de composition*, where they seem suitable for replacing the coloured wines of Spain and Central France.

"Japanese and Chinese Vines might, if cultivated in other places more temperate than the Normandy districts, and especially if these regions were always cool, yield still more interesting results; but at present it is merely certain that, in a relatively cold climate, where wine-making is unknown, they can, owing to their earliness, and the special qualities of their wine, be made particularly useful for viticulture."

METHODS OF PROPAGATION.

(Continued from p. 245.)

FOREST AND ORNAMENTAL TREES.—We now come to a large class—that of forest and ornamental trees, which are raised in nurseries by seed usually sown broadcast. The seeds of some of these require a certain amount of preparation before being sown, and the commoner method is to "pit" them, viz., to dig a hole, and in this to put a mixture of the fruits as they come from the tree, with sand or some kind of light soil, and then to cover with the surrounding soil, and leave the contents undisturbed till the following March or April. A better method is to select a plot of ground in a sheltered spot, make it solid and level with the spade, and then to spread the seeds of the Ash, Maple, or Sycamore, mixed with sand, &c., about a foot thick upon this, pressing it close together by trampling it, neatly levelling the edges with a spade, and covering it with a layer of soil. It should be left undisturbed till the following March or April. On opening the heap, the "keys" or seeds will be found so decayed that the small oval kernels or seeds will come out by simply rubbing them between the hands; or, if the winter has been a wet one, the "keys" may be sown direct from the pit or clamp. Some discrimination is necessary in the selection of the "keys"—as the winged seeds of the Ash and Maple tribe are generally called. As a rule, stunted and diseased trees are the most prolific of seeds; but seed should, if possible, be gathered only from robust trees. Doing this involves more time and trouble being expended, which is, however, well repaid in the vigour and free growth of the seedlings.

Most ornamental trees are grown for their distinct forms, the beauty of their foliage, and many for their flowers, and the bulk of them belong to the natural order Rosaceæ, which embraces the Rose proper, the Thorns, Arbutus, Crabs, Almonds, Cherries, Plums,

Sorbus, and Amelanchier. These produce abundance of blossom, which, of itself, makes the trees desirable; and, in addition, they give us bright-coloured fruits, and foliage which, in the autumn, has pleasing tints, thus prolonging their attractions some way into the winter. The fruits afford the natural and best means of propagating all of these which are not merely sports or seminal varieties. The seed has to be made fit for the seed-bed in many different ways. Those of a fleshy nature, as Crabs, Pears, Plums, and

up in the nursery, leaving such a distance from plant to plant, and between the rows, as is best suited to height of the tree; but it is a good rule always to allow plenty of space, and then the subjects, whether deciduous or evergreen, will develop naturally and make good specimens.

The fruits of flowering and other shrubs may be similarly treated; for instance, the juicy berries of the common Mezereum (*Daphne Mezereum*) may be rubbed in sand and the seed sown forthwith, as may those of the Aucuba, which now fruits freely in most strubberies, thanks to the introduction of the male plant from Japan by the late Robert Fortune. When grown from seed quite thirty per cent. of the young plants prove to be males, while every form of foliage results from the small green leaves of *A. japonica viridis*, to the large variegated ones of *A. j. latimaculata*, and *A. j. crassifolia*; and if berries have been taken from the variety called *A. longifolia*, which is the best to grow in pots for conservatory and winter-garden use, the still narrower-leaved kind will be found among the progeny, called by some *A. salicifolia*; indeed, there seems no limit to the varieties produced. If the fruit is not food fit for man, we have the satisfaction of knowing that all birds of the thrush tribe are very fond of it, and it therefore adds to the often scarce winter fare of these splendid songsters of the garden.

I will now indicate a few more trees and shrubs which are usually raised from home-grown fruits, though there are numbers raised in nurseries from seed imported direct from the natural habitat of the plants, or in some cases from the South of Europe, where these species have been naturalised. The following have all soft fruits that may be rubbed in sand to prepare them for sowing:—*Ampelopsis Veitchi*, and other varieties; *Arbutus*, the Strawberry-tree, *Berberis dulcis*, *B. Darwini*, and others; *Cotoneasters*, *Hookeri* and *frigida*; *Hollies*, in variety (want pitting); *Lycocystia formosa*, *Ligustrum vulgare*, and others; *Hypericum hircinum*, and some others; *Rosa rugosa*, &c.; *Sorbus aucuparia*, *S. hybrida*, and *S. intermedia*; *Sambucus racemosa*, and others; *Symphoricarpos racemosus*; *Chamaecerasus* and *Lonicera*s.

The following can be either pitted or sown direct into the ground, the first being a saving of time, and perhaps more certain. *Alnus* (the Alder), all kinds in wet soil; *Amorpha fruticosa* and its varieties; *Cercis siliquastrum*; *Colutea arborescens*; *Cytisus Laburnum* and other *Cytisus*es; *Genista* and *Spartium*; *Gleditsia triacanthos*, and *Robinia* in variety; *Staphylea colchica* and *pinxita* (Bladder-worts). *Esper.*

TREES AND SHRUBS.

THE UPRIGHT CEPHALOTAXUS (C. PEDUNCULATA FASTIGIATA).

I WAS agreeably surprised a short time ago to find no fewer than eight specimens of this uncommon shrub in an old Hertfordshire garden. They had in all cases attained to full dimensions, were in robust health, and showed the peculiar character for which this species of Conifer is remarkable—the lower tiers of branches horizontally arranged with the leaves in two rows, while those further up are strictly fastigate with spirally arranged foliage. In several of the specimens the lower branches covered a spread of from 10 feet to 12 feet in diameter, the foliage being of an intense and healthy green hue. Pollen catkins were produced plentifully on several of the plants, and on both the fastigate and horizontal branches. The soil is a stiffish loam on chalk, and as showing how well a tapered *Cephalotaxus* is for planting in the shade, I might mention that several of the specimens got little or no direct sunshine. I am now almost convinced that there are not three species of *Cephalotaxus*, *C. Fortunei* (pedunculata) and *C. drupacea* being identical. There are, however, wide differences in the male and female plants. *A. D. Webster*. [1]. *Fortunei* is very distinct. Ed.]

FIG. 97.—SLACHYURUS PEDUNCULATUS, HARDY, DECIDUOUS, SPRING FLOWERING SHRUB: FLOWERS, PALE YELLOW; KEW. (SEE P. 283.)

Almonds, by pitting; those of an intermediate character by mixing with sand and clumping; and lastly, those that have soft succulent fruits, as Cherries, Sorbus, and Amelanchier, by being rubbed in sand between the palms of the hands, afterwards allowed to get dry, and then sown sand and all in drills, or in beds broadcast.

There the seedlings may be left for at least two years, when they should be lifted, the tap root shortened with a sharp knife, and the plant quartered

COLONIAL NOTES.

TECOMA STANS. *Juss.*

On the sides of hills, along the cuttings by the roadside, and in nearly all open localities in the lowland districts, this *Tecoma* is a feature of the flowering vegetation this month (March) in Grenada. Our season, which should be, according to man's idea of the climate of Grenada, dry for the present time, and also for the next two months, is now like an English April month. Dry weather we have had for the past few weeks, and now the nice spring-like showers and the warm, bright sun are hastening many plants and trees into flower, and among them is this *Tecoma*. Grenada folk know it by the name of White Flambeau—although the colour of the flowers is a rich yellow—in contradistinction to the Red Flambeau, the Poinciana regia, a member of a different natural order of plants, and a native of Madagascar. The opposite leaves of the White Flambeau are made up of a few long, pointed leaflets, toothed along their margins. The inside of the tubular flowers have several longitudinal red lines; several flowers grow together at the tops of the branches. It is a small tree, or shrub-like bush, and its seed-pods in shape not unlike French Beans. *W. E. Brouway, Grenada.*

THE WEEK'S WORK.

FRUITS UNDER GLASS.

By F. HARRIS, Gardener, Earl's Court, Londonby.

Cucumbers.—The early plants are now bearing fruits, and should be liberally treated, so as to keep them in vigour, and nothing is better in this direction than top-dressings of the mixture mentioned in a previous Calendar, and manure-water afforded occasionally. The bine must be kept within bounds by pinching the points, removing old shoots and leaves, and allowing young bine to extend, all crowding being avoided. The Cucumbers, if setting freely, should always be thinned out, so as to obtain good-looking fruits, and not exhaust the plants unduly. If red-spider or mildew should become apparent, the plants should be syringed for the former with flowers-of-sulphur mixed with water, and dusted with dry sulphur in the latter case when the leaves are damp. Where Cucumbers are obtained during the summer from hot-bed-frames, the present is a suitable time to start a few of them. Frames which have been in use for early vegetables may readily be adapted for Cucumber and Tomato culture. For Cucumbers the spent soil should be thrown out, and some fresh stable-dung and leaves stirred into the old materials; and if dry, the whole should receive some water, so as to set up fermentation. When this has occurred, put in small hillocks of roughish fibrous loam, and set out the plants, more soil being added as the roots of the plants find their way to the top. The treatment of these frames is similar to that recommended for early houses, covering the lights on cold nights, and taking precautions against strong fumes from the dung. Sow more seeds at intervals in order to keep up a supply of plants.

Strawberries.—The mid-season varieties, if they have been slowly forced, will be now coming into bearing, and if given plenty of air while ripening they will be of grand flavour and appearance. They will require careful attention in the matter of affording water, plants on shelves in forcing-houses requiring water in sunny weather twice if not thrice a day. If any plants get very dry, immerse them in water for a few minutes. The fruits of these varieties may be more freely thinned than was called for by the early fruiter, taking six as the average number of fruits to be left for ripening on plants growing in 32's; and smaller pots than this size should not be used for these, and later fruiter. If the shelves are covered with spent Mushroom-dung, or thin turves, and thin boards about 5 or 6 inches deep are placed edgewise on the shelves, much labour in watering the plants will be avoided. Such varieties as British Queen, Waterloo, and Dr. Hogg, which may be standing in cold frames, will be coming into flower, at which stage the ventilation must be well attended to, and the lights covered at night if frost be feared. Should aphides appear on these plants, fumigate them as soon as the flowers are set; and if mildew be noticed, dip the foliage in a mixture of flowers-of-sulphur and water, which is more effective as a cure than dry sulphur.

THE ORCHID HOUSES.

By W. H. WIMPEY, Orchid Grower, Bedford, Dorking.

Cattleyas and *Laelias*.—*C. Percivaliana*, *C. amethystoglossa*, *C. Gaskelliana*, *C. labata autumnalis*, *C. Harrisoni*, *C. guttata*, *C. Leopoldii*, *C. Schaffneriana*, *C. Trianae* and its many distinct varieties, also such beautiful hybrids as *C. exoniensis*, *C. Lord Rothschildi*, *C. Harrisii*, *C. Pleidona*, *C. Fausta*, *Laelio-Cattleya elegans*, &c., are in various stages of growth. Some of them have just done flowering, and are producing a number of young roots from the last made bulbs; others are commencing to break, and as the new growths soon emit fresh roots, in such cases the operation of re-potting or top-dressing should be proceeded with at once. Any plants that have sufficient root for further development should be relieved of the old material from their pots, and be re-potted with fresh compost. Unhealthy specimens should be turned out of their pots, and thoroughly cleaned, cutting away all dead roots and useless back pseudo-bulbs, repotting them into pots as small as they can conveniently be put into. In repotting healthy established plants, remove them from the pots with as little mutilation of the old roots as possible. Place the plants into pots of one or two sizes larger, but strictly guard against over-potting. Let each pot be two-thirds filled with crocks, over which it is easiest to place a thin layer of sphagnum to support the compost, which should consist of equal parts of the best sphagnum-moss and fibrous peat. After thoroughly mixing the compost, it is advisable to sift it roughly through a coarse-mesh sieve to get rid of the fine soil. Work some thick pieces of crocks in with the compost in order to prevent the soil from becoming sour. Pot the plants firmly, keeping the base a trifle above the rim, and tie a few of the pseudo-bulbs to neat sticks, that the plant may be held firm. Afford water with great care during the first few weeks after re-potting, as much moisture is likely to cause the old roots to decay. Until each plant is well re-established, simply moisten the compost around the edge of the pot, and keep the surroundings fairly moist by syringing between the pots two or three times a day. Bysuch methods the roots will soon grow and attach themselves to the sides of the pot, when the amount of water at the root may be gradually increased, affording it at moderate intervals in preference to keeping the compost constantly saturated. Until the roots are in full activity, the plants should be shaded from strong sunshine, or some of the lower leaves may turn yellow and fall off. Plants of *Cattleya Mendeli* *G. Schaffneriana*, *C. Mossie*, *C. Skinneri*, *Laelia tenebrosa*, and the different forms of *L. purpurata*, also *Laelio-Cattleya Cahaniana* × *L. C. Arnoldae* ×, and others, whose flower-spikes are developing, will require extra large supplies of water at the root till the flowers expand, when they should be kept rather on the dry side until the new breaks appear. Any plants of the species or hybrids enumerated that have failed to produce flower-spikes, or those that have deteriorated, may be re-potted at once, as the plants generally commence to root at this season. *C. speciosissima* may also be re-potted now, and suspended close to the roof glass of the Mexican-house. *C. Walkeriana*, now producing spikes from the apex of a small slender shoot at the base of the youngest pseudo-bulb, is quite distinct from all other *Cattleyas* in its mode of flowering, and in forming its new growth, which commences immediately the flowers fade, from the rhizome at the base of the old flower-stem. For this dwarf-growing species, teak-wood baskets are very suitable, and these should be suspended close to the roof-glass. Very little material is needed for them to root in; in fact, they appear to grow more vigorously when the rhizomes push their way along the edges of the basket. During the resting season the hard, round pseudo-bulbs of the *Cattleya* rarely shrivel if they are properly matured, but remain plump for several months without receiving a drop of water at the root, and even during the growing season very little water is necessary. *C. Lawrenceana* now in flower should be placed at the cooler end of the house, and when the blooms have faded, the amount of moisture considerably reduced, but not sufficiently so as to cause shrivelling. *C. Bowringiana* is now at rest, and will require identical treatment. The same remarks apply to the lovely *C. Schroblerae*. *Cattleya superba* when commencing to grow may be rebasketed if necessary, by fixed to a piece of tree Fern stem, suspending it near the roof in the hottest house. Afford a moderate shade and an abundance of water until the flowers open, when the plants may be removed to a light position in the *Cattleya*-house to mature their growth. *Cattleya citrina* now producing its handsome and fragrant blooms, should be kept in a cool sunny

house, and afforded only a very limited quantity of water at the root. The flowers will then remain fresh for several weeks. The dwarf-growing *Laelia pumila*, *L. prestans*, *L. Dayana*, and *L. marginata* will require very little root-moisture; and they should be placed at the warmest end of the *Odontoglossum*-house until growth recommences.

PLANTS UNDER GLASS.

By G. H. MAVCOCK, Gardener, Luton Ho Park, Luton.

Euphorbia Jacquiniflora.—Cuttings of this plant which are rooted should be potted off without delay, and before the cutting-pots fill with roots. It is a delicate operation, and must be carefully done, or the plants will suffer greatly; and some growers, to avoid root disturbance and its ill effects, repeat without dividing the cuttings. If the stock is limited, it is the better way, as there is then no fear of loss of cuttings. Those that are potted must be kept in brisk heat for a time, not much water being afforded them before roots have fairly well filled the pots.

Hippocrepis (Amaryllis).—As these bulbs pass out of flower in a cold-house, remove them to a warm one in order to keep them growing, and syringe the foliage night and morning on fine days, closing the house or pit soon in the afternoon. The withholding of water from these bulbs should not take place before the bulbs are thoroughly matured, and the foliage shows signs of maturity. In kinds that have the evergreen habit, the matured condition of the bulb is the only guide. Those who can grow them on a tan or leaf-bed may let them root through the hole in the pots, and when water is withheld if they need not be disturbed before the autumn. When the foliage falls off naturally, the bulbs, if not standing in a bed, may be rested by turning the pots on their sides.

Achinaceae.—Any varieties may now be introduced into heat as required; and cuttings of desired varieties may be taken, which, if inserted in sandy peat, will take root readily. They may be struck in pots in this manner so as to flower them without any re-potting. Afford the cuttings a temperature of 65° to 70°, and the tubers one of 55° to 70°. The latter degree of warmth will likewise suit the earlier successions.

The Fernery.—The watering and syringing of the plants, and the keeping up of the necessary degree of humidity, are matters that require close attention at this season. Should the fernery be exposed on the south side, it must be shaded from the sun. Thrips are apt to infest *Fern* Ferns, and must be watched for, and the plants freed of them by syringing and keeping the stems and surroundings humid, a dry air always favouring their increase. I do not advise the fumigation of Ferns, but if badly infested, some means will have to be taken, or the fronds will soon become disfigured. In such a case, the infested plants should be removed to another house for vapouring, not fumigating.

THE HARDY FRUIT GARDEN.

By H. W. WARD, Rayleigh, Essex.

Figs.—It is well to defer the pruning and training of Fig-trees until they begin to push into leaf, which may be about the commencement of May or a little later. The wounds will now bleed but very little, by reason of the opening leaves drawing away the rising sap, which, if the trees were pruned earlier in the season, would flow through the wounds; moreover, it can now be easily ascertained which of the shoots are best furnished with embryonic fruits. These, as a matter of course, should be retained, cutting clean away as many old and less fruitful branches as are not required to cover the wall-space allotted to each tree. A space of 6 inches should be left between the branches, and the tree is best trained in the fan shape. One shoot of the current year's growth should be laid in between these in due time, and the points pinched out of any extra strong shoots when about 18 inches long, and the weaker ones at 2 feet. This will promote a balance of growth in the individual trees, assist the fruits to complete their swelling, and tend to the formation of fruit for the following year. Secure branches to the wall by means of shreds and nails, and be careful to leave sufficient room in the shreds to admit of large growth being made—the same remark applies to trees which are trained to wired walls; the ties of raffia or bast being made so loose that the bark will not be injured. As soon as the pruning and thinning of the trees have been completed, loosen the surface-soil for a space of 3 or 4 feet out from the Fig-wall with a digging-fork.

and then give the entire border a good watering. Lay on a surface-dressing of short dung to the thickness of about 3 inches, and repeat the application of water at the roots several times during each month from May to August. The following varieties are excellent, viz., White Beauty from Turkey, Castle Kennedy, and Brunswick. The two last-mentioned varieties, under skillful treatment, produce large handsome fruits, fine in quality as well as in size—fruits which, on the exhibition-table or dinner-table are always admired.

Removing Root-suckers from Wall Trees.—Root-suckers should be persistently removed, as they rob the tree considerably when allowed to remain. It is not much use to cut them off with the Dutch-hook; they should be pulled out, using the spade if necessary, but exercising care lest in severing these bunches of suckers from the main roots the latter become injured with the implement in the process. Suckers proceeding from the main stems (stocks) of grafted fruit trees should be rubbed off as soon as they appear. Plums and other kinds of fruit worked on the Plum are the most troublesome in producing root-suckers, consequently a watchful eye should be kept on them.

THE FLOWER GARDEN.

By CHARLES HENSON, Gardener, Droppore, Maidenhead.

Annals.—In order to insure a fine summer display of annuals, sowers should now be made of the following—*Bartonia* aurea, *Linum grandiflorum coccineum*, which are excellent for filliug odd beds where the usual kinds of bedding plants are not desired, or the supply of the latter is not equal to the demand. For adding to the display in the herbaceous beds and borders, annuals are useful for filling vacant spaces. The best effects are produced not by an indiscriminate mixture of many species, but by the employment of a few, the names of which I give below. At Droppore there are many large beds which are planted with *Peonies* and other herbaceous perennials, and when the chief sowing of annuals is made at this date, the bare ground in these beds is sown with one species or variety of annual in a bed, the colours being varied; as, for instance, *Linum grandiflorum coccineum* is sown in one; in another *Goldilocks bicolor*, in others *Clarkia marginata*, fl.-pl., *Nasturtium Tom Thumbs*, scarlet and yellow; *Godelia* Whitey and *Duchess of Albany*, and others. Where taller subjects would make a nice display, and are permissible, the *Crocopsis* in variety, *Lavatera trimestris*, *Moloch grandis*, *Coroniflora*, and *Chrysanthemum Burdigalense*, and others, should be sown. Sweet Peas may be sown in rings, 2 to 4 feet in diameter, on the herbaceous borders, where space admits, placing a few sticks in the centre of each, which will eventually cover with bine. A few days before the seeds of annuals are sown, the soil should be hoed, so as to kill weeds, and give to the surface a fine tilth, and, if necessary, it should be raked over, to render the surface level, and to remove stones, &c. The sowing of annuals in borders may take the form of lines, and large and small plots or patches, the seeds being sown broadcast; or in the case of large-sized seeds, sown in shallow drills. Very minute seeds should be sown on soil that is made firm and smooth, covering the seeds with fine soil from the potting-bench, or the border itself. Some seeds may be left uncovered, but protecting them from the birds by pieces of netting, or by hand-glasses. If the seeds are known to be new, or a large percentage of them, as has been proved by testing them in pots in heat, are capable of germinating, they may be sown thinly, otherwise rather thick sowing may be advisable. Never let the seeds get water or lack of timely thinning. If slugs abound, use mixed lime and soot occasionally on moist evenings.

Herbaceous Peonies.—These showy plants will require to be secured by ties of bast to short stakes, in order to prevent their falling over, and the flowers lying on the soil and being thereby spoiled; moreover, the effect of a clump of *Peonies* is finer if the flower-stems be kept erect. Stakes are unsightly objects if conspicuous, and it is my practice with all the stronger-growing varieties, especially those of *P. officinalis*, *P. Pottii*, and others of that type, to pass a piece of tarred string around each clump in 4 under the foliage where the flowers are in bud, drawing the head together fairly tightly, and using no stakes. Treated in this manner they keep erect and spread open just enough by the time they are in bloom to look natural, and show off the blossoms to advantage. For tall-growing varieties with slender stems I use one short stake, to which the string is fastened, the top of the stake being kept out of sight beneath the leaves.

Forsythias.—These handsome flowering shrubs having now mostly passed out of bloom, require, in whatever form they are grown, some amount of annual pruning, and the shoots made now, and those that result from this pruning, will furnish the flowering-wood for another year. The flowering shoots of this year should be shortened back to three or four breaks, and other pruning required may be done at the same time. *Forsythia suspensa* and *F. viridissima* are effective shrubs for planting in the open in the south of England, but in cold parts the shelter of a wall is required by both. As wall plants, the shoots should be nailed in loosely. If the soil around the bushes is found to be exhausted, some of it should be replaced with turfy loam and rotten manure.

THE KITCHEN GARDEN.

By W. FORD, Gardener, Highclere Castle, Newbury.

Beetroot.—Seeds may now be sown for the main crop of Beet on land that was well manured for some earlier vegetable crop, fresh manure causing coarseness of growth at the top and bottom. If the seed be good and fresh, sow thinly in drills 15 to 18 inches apart, and afford a slight dressing of common salt at the same time, raking it in when covering the seeds. The best kind of land for Beetroot is that which is rather light, fairly rich, and of good depth. Let the seedlings be singled in good time to a distance of 3 inches apart in the first instance, and then, if losses should occur, there are plants available for filling the rows later on. For transplanting to be successful, the plants must be allowed to attain a height of not less than 6 inches, and if the job be performed in showery weather, good roots will result. At the final thinning, allow the plants to stand one foot apart. Good varieties are *Dell's Crimson*, *Sutton's Blood Red*, one of the best for general use, the roots being of good colour, middle-size, and the crown short and compact; *Pragnell's Exhibition* is larger, but lambs-ear and good, and is better for exhibition and early consumption; *Cheltenham Green Top* is first-class, has green foliage, and deep red flesh. A little seed of the Turnip-rooted variety sown at the same time will be fit for use several weeks in advance of the long-rooted Beets, and is especially valuable in shallow soils. *Crimson Ball* is a greatly improved form of it. When thinning these Turnip-rooted Beets, they may be left at 6 inches apart.

Beans.—The first sowing of Runner Beans may now be made, for it is only in favoured localities that it is safe to sow these out-of-doors before May 1, as besides their tenderness in a young state, seed sown at an earlier date, germinates badly, if at all. The soil for these should have been deeply dug, and made rich with manure. Sow in drills 3 inches deep, placing the seeds 3 to 4 inches asunder, and sowing the plants to 1 foot apart. In this manner gappy rows are avoided. The surplus plants may be utilised elsewhere, as Beans bear transplanting well. Many prefer to sow double rows, the rows being about 9 inches apart; but for all practical purposes, single rows are to be preferred. The rows should run north and south, and be, at the least, 6 feet apart, a catch crop of some kind being taken from the space between the rows. The best and most succulent Beans are grown in trenches made as for Celery. If Runner Beans are required very early in the season, sow the required number of seeds singly in small pots, and place in a warm house or frame, and as soon as they are well up, repeat them on into 32's, and when re-established remove to a cold frame, always allowing the plants plenty of air. Tie up the stems carefully as growth advances, and harden thoroughly before planting out in the third or fourth week in May. If proper care be taken of such an early sowing, Beans can be gathered a fortnight before those sown in the open ground. For exhibition or general use, nothing surpasses a true *Ne Plus Ultra* or *Sutton's Best of All*; whilst those preferring a white-seeded Bean will find nothing better than *Chelsea Giant* or *Carter's Jubilee*. A good breadth of *Ne Plus Ultra Dwarf Bean* sown now on a warm border will furnish plants that will bear pods some time before the Runners are ready.

THE APIARY.

By EXPERT.

Fumigating Hives.—At this season of the year, when the bee-keeper is busy with his stock, I would offer a word of warning to those who find it necessary to use a fumigator. On Saturday I had occasion to

use the ordinary bellows-fumigator, and inadvertently hauled a piece of rag that had been used for dressing an oil-lamp. Of course, instead of smouldering, a flame was urged up through the fumigator, igniting the netting, and enveloping my head and eyes in flames. I received a few nasty burns upon my ears and forehead. I trust this may be a timely warning to other small bee-keepers.

Remedy for Bee-stings.—For the benefit of bee-keepers who have much to do with bees, I want to give a word of advice to those who get stung more often than is quite pleasant; that is, extract the sting as soon as possible, and apply a little of "Hudson's Dry Soap," mixed into a sort of paste over the place. I find it almost instantly relieves the pain, and stops the swelling. I am sure many bee-keepers will be thankful for the "tip."

Shade for Bees.—Shade is an advantage undoubtedly, but we may have too much even of a good thing. I know of several cases where stocks are always shaded by dense foliage. The hives are consequently green and dirty-looking, and the stocks a little behind those, equally well cared for, standing in the open. Temporary shades might be fixed over the hives during very hot weather, but in such a manner as not to be confusing to the bees when returning home from the fields. In America, one noted apiary presents a most pleasing appearance, and it has for the system of shading adopted been much copied. In front of the hive a fine vine is grown, and trained to a fixed trellis-work. The foliage is a great protection to the hives, besides giving an unusual and picturesque effect to the scene. In England I am not aware that anything of the kind has been tried, probably because we do not experience such a continuance of hot weather as our American cousins. Here, by outer cases to the hives, free circulation of air round the supers, a free entrance, and painting the hives so that the heat is reflected instead of absorbed, we get along without being troubled much by the heat.

The Prospects.—Since my last notes appeared, a very gradual improvement has taken place in things apicultural. That all-important factor, the weather, has mended somewhat; and though the bees are still backward, and all things very early sown abandoned, there is yet ample time for bees to get into condition for the main honey-flow. A late spring by no means foreshadows a bad season, but rather the contrary. As it was, however, March was a cruel month for the poor bees, and although it finished badly, April commenced worse. During the first week of this month I stood watching the bees issuing from a longish row of hives, and within a few minutes counted several hundreds go forth, and did not see twenty come back. I estimated that during the prevalence of that chilling wind every bright hour cost my outside apiary not less than a pint of bees; in fact, a subsequent examination of the stocks since the change has verified my estimate. Bearing in mind, then, that we are several weeks behind, and that this ground has to be recovered as speedily as possible, I have for the last ten days been syrup-feeding, giving good, thick, warm syrup every evening. Then as opportunity occurs, a little store from natural sources being obtainable, my charges are again getting into good heart. The 11th was the turning-point of the season; on that day the air became once again scented with the perfume of the spring breeze, and all the bees at work bringing in honey-pollen. I was sorely tempted to put a rack or two of shallow frames on, but it is not to be just yet. I have this spring been able to verify the advantage of a bee-house as winter quarters for bees. No stocks of mine in the open equal in strength those indoors, comparisons averaging nine or ten frames covered with bees on indoor stocks against seven or eight frames, and even less, outside.

Spreading Brood.—I would advise all to hesitate before spreading brood nests at present, and even when "spreading" is ventured on, not to do it by inserting an empty comb or, still worse, a sheet of foundation, or may be a starter on. Enlarge the brood-nest if at all from the side, taking the last frame containing a little brood and insert it in the centre; the queen if cramped for room will soon find out this comb, and that there are empty cells in it available for her purpose. Wait, however, till the warmer nights have come to stay before splitting the brood-nest in two by either an empty comb or a sheet of foundation, which is a veritable dummy for the time being, and should a sudden drop in the temperature occur it will cause the majority of the bees to cluster on the side where the queen is. This brings about to a certainty "chilled brood" along the lower margins of the combs on the other side.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER. Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible, and duly signed by the writer. Undesired, that is, material will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction in these pages, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

APPOINTMENTS FOR MAY.

SATURDAY,	MAY 1	Opening Day of the International Exhibition at Hamburg, Germany. Société Française d'Horticulture, London. Isle of Wight Horticultural Society, Meeting.
THURSDAY,	MAY 6	Linen Society, Meeting. Ayrshire Gardeners Society, Meet. Brighton and Sussex Horticultural Society, Show.
FRIDAY,	MAY 7	Royal Botanic Society, Lecture.
SATURDAY,	MAY 8	Royal Botanic Society, Meeting.
TUESDAY,	MAY 11	Royal Horticultural Society's Committee and Lecture.
FRIDAY,	MAY 14	Royal Botanic Society, Lecture.
TUESDAY,	MAY 18	Somerset County Agricultural Show, at Minehead (2 days).
WEDNESDAY,	MAY 19	Royal Botanic Society, Summer Exhibition at Regent's Park.
FRIDAY,	MAY 21	Royal Botanic Society, Lecture.
SATURDAY,	MAY 22	Royal Botanic Society, Meeting.
MONDAY,	MAY 24	Linen Society (Anniversary). Bath and West of Southern Counties Show at Southampton (5 days).
WEDNESDAY,	MAY 26	Temple Show of the Royal Horticultural Society (3 days). Gardeners' Royal Beneficial Institution (Annual Dinner).
FRIDAY,	MAY 28	Royal Botanic Society, Lecture.

SALES FOR THE ENSUING WEEK.

MONDAY,	MAY 3	Carnations, Peonies, Dahlias, Iris, Phloxes, &c., at Frothero & Morris' Rooms.
TUESDAY,	MAY 4	The Hawthorns Collection of Established Orchids, at Frothero & Morris' Rooms. Japanese Lilies and Maples, Carnations and Peonies, Greenhouse Plants, Ornamental Palms, Herbaceous Plants, &c., at Frothero & Morris' Rooms.
WEDNESDAY,	MAY 5	Border Plants, Shrubs, Roses, Lilies, Bulbs, Palms, and Ornamental Plants from Ghent, at Stevens' Rooms.
FRIDAY,	MAY 7	Imported and Established Orchids, from Messrs. F. Sander & Co., at Frothero & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—52°.

ACTUAL TEMPERATURES:—

LONDON.—April 28: Max., 66°; Min., 51°.
PROVINCES.—April 28 (P.M.): Max., 65°, 8 Counties; Min., 44°, Aberdeen.

It is conceivable that, in certain concurrent circumstances, our food supply might be cut off, and we should be at the mercy of whatever enemy happened to be attacking us. As to the result, we shudder at its contemplation.* It so happens, happily, that there are a great many "ifs" in the case, and this being so, we can read Mr. MARSTON'S pessimistic book with a little more complacency than would otherwise be the case. It is not within our province to discuss the political or the strategic aspects of the question, but any of us can see clearly enough

that if Mr. MARSTON'S figures and inferences be correct, we might be in very sad case indeed. Mr. MARSTON shows graphically that we now import over five times more Wheat than we grow. Moreover, it is evident to cultivators that our climate is, relatively speaking, not favourable to Wheat-growing, and that the quality of the product is not so good as that ripened under more favourable conditions.

Mr. MARSTON'S idea is gradually to accumulate an amount of Wheat equal to that imported in one year, and store it against the evil day. This project involves a compulsory exchange of it for the new corn of each year's importation, and other political and financial problems which we must leave to be discussed by those more familiar with the subject. The question we can concern ourselves with is this, what can we do to make our home-grown loaf bigger? Can we do anything? We believe we can, but not with the aid of Wheat. Our climate is too uncertain to permit of that. But there are other cereals, such as Barley or Oats, almost, if not quite, as nutritive as Wheat, which could be grown here with a greater degree of certainty than Wheat. Then there are the pulses—Peas, Beans, and the like—which are considerably more nutritious than Wheat, and which could be grown to help out under the distressing circumstances depicted by Mr. MARSTON. Potatoes, too, might be of service, and green vegetables, roots of various kinds, and hardy fruits, would all serve to ameliorate our unfortunate plight. Of course, it would be difficult to get stores of these things, and it would take time to grow them. At any rate, some of the items we have mentioned would be in store, so that we should not be dependent wholly on the stock of Wheat there might be in the country. It must be admitted, however, that our resources would be of extremely little importance in the face of such a catastrophe as he shows is possible. Fortunately, it is not very probable that we shall ever have any such combination of circumstances to face. But if we do, the gardeners and the farmers must do their parts. The market-gardeners, as it is, get a vast deal more out of the soil than the avorage farmer does; and the increased knowledge brought to bear on cultural matters now-a-days has a tendency, which is already visible, to render us less dependent on the foreigner than we were. That we can ever be wholly so, it would be chimerical in the extreme to expect; and while we continue to be such good customers to our rivals, there is all the less reason for them to make war upon us. After all, Wheat is not the only food we require, and much of the food which is not derived from that source could, as we have said, be grown within our own boundaries. We recommend Mr. MARSTON'S book to the careful perusal of our readers, for if its perusal has any influence in increasing the amount of our home supplies, and the increase of our food reserves, the feeling of alarm his book is calculated to arouse will be, in a measure, compensated for.

AN UPROOTED ARAUCARIA IMBRICATA (Supplementary Illustration).—The heavy gale of March 3 last committed great havoc in various parts of the country, and many fine trees were levelled with the ground, notably some of the Cedars of Lebanon at Goodwood. Our supplementary illustration (fig. 98) shows a fine specimen, probably one of the earliest-planted *Araucaria imbricata*, standing in Sir ELLIOTT LEE'S grounds at South Lychett, near Poole, which was overturned by the gale. It was planted in 1832, and

was 60 feet in height, and it seems to have had a diameter of 3 feet near the base. Like most of the specimens that have acquired age, the stem was bereft of branches for one-fourth of its height, but the crown was massive and healthy, a fact that must have greatly contributed to its overthrow. *Araucarias* being wide but not deep rooters.

ROYAL HORTICULTURAL SOCIETY.—The following questions were put at the late examination in Horticulture. Eight questions only had to be answered; four from Division A, and four from Division B:—

DIVISION A.

ELEMENTARY PRINCIPLES.

1. What are the three chief mineral ingredients of a soil? Name garden plants or shrubs which delight in each kind respectively.
2. What differences may be expected from growing unripe, perfectly ripe, and long-kept seeds respectively?
3. In transplanting, why is it necessary to preserve the extreme and most delicate fibres of the root-fibrils?
4. Why does covering Rhubarb, radishes and lengthen the leaf-stalks and stop the growth of the blades?
5. Describe the structure of a Hyacinth bulb, and explain why the Dutch method of sashing or hollowing out the bottom induces the formation of bulbils?
6. What are the essential conditions for successful grafting?
7. How does the structure of a Plum differ from that of an Apple? Explain the origin of each.
8. Name the Natural Orders or Families to which the following plants belong:—Cyclamen, Rhododendron, Clematis, Stock, Pelargonium, Borage, Potato, Onion, Parsley, and Turnip.

DIVISION B.

HORTICULTURAL PRACTICE.

9. Explain the process of cross-fertilisation in garden flowers, and give examples of both hardy and exotic plants that have been improved thereby.
10. After seed of the Chinese Primula has been ripened, describe the method of sowing and subsequent treatment of the plants up to the period of their flowering.
11. What is the native country of the Celery plant, and under what conditions does it grow naturally? Give a short account of its culture, such as time of sowing and subsequent treatment.
12. When, and under what conditions, is Sea Kale found in a wild state? Describe its culture, and state the year of year it is in use.
13. Where is the common Asparagus said to be found in a wild state? State all you know of its culture, and for how long a period it may be had in use.
14. Give an account of the Apple. How are the trees propagated? State what you know of its culture, and the diseases to which the trees are liable, and the remedies. Name one good cooking variety for use in each month from August to April inclusive.
15. State all you know about the Raspberry. What sort of soil is best adapted to its culture? Give method of training and pruning, and the best varieties to cultivate, both yellow and red.
16. Give an account of the usual method of Gooseberry culture adopted in gardens; and also the Laneshire method to obtain prize fruit. Name six of the best prize varieties, and six best for ordinary garden culture.

"**KEW BULLETIN.**"— "Appendix ii, 1897" is devoted to an enumeration of all the new introductions in the way of garden plants during 1896. Such lists are very valuable in botanical libraries, and on editor's tables. We trust that at the end of every quinquennium, an index of the names published in the preceding period will be issued.

HAMBURG GENERAL EXHIBITION.—During the last few days an important addition to the objects sent to the exhibition has come to hand from Messrs. W. A. MANDA, South Orange, New Jersey. These will be exceedingly interesting to the German amateurs and gardeners, as they consist almost exclusively of novelties from Japan, and are still unknown on the Continent, as Lilies, Peonies, Acers, and carnivorous plants, said to be capable of enduring a continental winter. Among this contribution of Mr. MANDA'S are American novelties in Roses and Canas.

THE CARROT-FLY (PSILA ROSÆ).—The Board of Agriculture has issued a leaflet dealing with the life-history of this injurious insect, and the best means to adopt to get rid of it. Carrots are frequently much injured by the larvae or maggots of this fly, which bore into and feed upon their roots, living upon them, and causing them to become brown or rusty, and finally rotting. Early Carrots are not often

* *War, Famine, and our Food Supply*, by R. B. MARSTON (SAMPSON, LOW, MARSTON & CO.)

FIG. 98.—*ARTOCASIA HIBERATA* AT SOUTH LYCHETT, OVERTURNED BY THE WIND, MARCH 3, 1897. (SEE P. 288.)

materially injured, as the fly does not, as a rule attack the roots until the middle of May. Carrots badly attacked by this insect have deep cracks in the roots in which the larvae are found. These frequently extend to the centre of the roots, and cause them to rot. The tops become brown, and wither away, and in the early stages of the attack, when as yet there are only a few larvae in the roots, the foliage changes and betrays their presence. Copies of the leaflet can be obtained free of charge and post free on application to the Secretary, Board of Agriculture, 4, Whitehall Place, S.W. Letters of application so addressed need not be stamped.

THE LATE W. G. HEAD FUND.—This has now been closed, and the balance, after payment of medical, funeral, and other accounts, has been handed to the widow, who desires to most heartily thank all who so kindly assisted in meeting the very heavy expenses incurred during her husband's long and painful illness.

BARLEY AS A BASE FOR PORT WINE.—Agriculturists generally, and in the eastern counties especially, may be pleased to learn that their Barley crops can be placed to other use than now obtains, that, with the assistance of the laboratory expert, they may become manufacturers of port wine! This is on the authority of H. B. M.'s Consul at Naples, who, in describing the operation, says:—"The Barley is first malted, then the bacilli of port wine are introduced into the mead, where they ferminate incontinently and transform it from immature beer into the richest port. When the animals have done their work they can be sterilised, a sufficient stock of microbes being preserved in the laboratory for further use." Perhaps the Board of Agriculture, or some energetic agricultural society, will take the matter in hand and furnish our agriculturists with a new industry, a new means of paying the rent; or perhaps better still, those who now occupy themselves with brewing "a peck or want," or larger quantity, may find it to their profit to turn out port from Barley-meal by the hog-head.

ORCHIDS IN FLOWER AT MESSRS. PROTHEROE & MORRIS' ROOMS.—At every Orchid sale at Messrs. PROTHEROE & MORRIS' ROOMS, Cheapside, an interesting display of these plants in flower may be seen, and probably many a casual visitor is thereby induced to commence cultivation of Orchids. On Friday, April 23, there was an unusually fine display, consisting of Cattleyas, Lawrenceana, Schroderea, Schilleriana, Mossia, citrina, Achlandia, and Mendell; *Lælia purpurata*, and others. *Odontoglossum*, triumphans, crispum (some of the forms being finely spotted), *Pescatorei*, Hallii, cordatum, Roezlii, cirrosum, Ruckerranum, and many crosses. Among *Cypripediums* there were in flower about fifty different species and crosses. A large number of *Dendrobium*s, one fine specimen of *D. Dalhousianum* being worthy of an exhibition stand. Of *Oncidium*s, *Vandas*, and other genera, there were also numerous representatives.

NEW CORN PRODUCT.—The discovery that the pith of the corn stalk can be used in the construction of war vessels is likely to be of benefit to agriculture in more than one way. The chief use of this pith is for a packing between the inner and outer shells of the vessel, so that when pierced by a projectile it will absorb water and swell so rapidly as to close the opening before the vessel leaks to a dangerous extent. Experiments with this pith have been so satisfactory that it has been adopted in the construction of all our new vessels of war, and European nations have commissions for investigating the same material, so that the use of corn pith will make a market for what was once a waste product. In the process of extracting this pith the blades and husks are removed, and the stalks are cut into small pieces. When the pith is taken out from this stalk, the remainder is ground up into a flour-like substance which resembles bran. Some experiments with this "new corn product," as it is called, have been made at the Maryland Station with the remarkable result that it is found to contain eleven per cent. more of digestible matter and

two per cent. more of digestible protein than the whole fodder does when shredded. It contains as much digestible matter as the corn blades, and more total digestible matter and half-of-one per cent. more protein than Timothy hay. It does not contain as much digestible albuminoids as Wheat bran, but it equals that food in the total amount of digestible matter. It keeps as well as bran or Cotton-seed meal. It is in such condition that it can be uniformly mixed with any ground grain, and when used as a base it is possible to make a complete and normal ration for stock in one bulk without the necessity of feeding grain and hay separately. Animals fed upon such a ration eat it with relish, and keep in normal condition. Since there is only one pound of pith to fourteen pounds of blades, husk, and stalk, this new material amounts to a very considerable portion of the fodder. *Garden and Forest.*

BULLETIN DE LA SOCIÉTÉ FRANÇAISE D'HORTICULTURE DE LONDRES.—We have just received a copy of the annual bulletin for the past year, and are much gratified to find that substantial progress during 1896 has to be recorded. The French Horticultural Society of London has long been doing an excellent work, and its President, Mr. GEORGE SCHNEIDER, of whom a capital portrait is given as a frontispiece to the volume now under notice, is deserving of the warmest encouragement in his efforts to promote and extend good feeling among English and Continental gardeners and nurserymen. From a financial and numerical standpoint, the Society must be congratulated. Many of the leading horticulturists in England and abroad have lent their support to the work that is being accomplished, and the interchange of situations between young gardeners on both sides of the channel cannot fail to have a beneficial effect on those who have the courage to expatriate themselves for a while in order to enlarge their knowledge and experience. Briefly stated, the contents of the *Bulletin* comprise the annual report, rules, lists of officers and members; proceedings at the meetings, including the last annual dinner, which was presided over by Mr. GEO. NICHOLSON, of Kew, and was unquestionably one of the most successful ever held; the balance sheet, contents of the Society's library, and the best of the papers read by the members on various subjects of horticultural interest. All particulars concerning the Society can be obtained from the Secretary, at the head-quarters of the Society, 19, Old Compton Street, Soho, W.C.

OROBANCHE ON HUEA.—MESSRS. H. CANNELL & SONS send us a plant of *Huea elegans* killed by the growth on it of *Orobanche minor*. We never saw the *Huea* attacked before. Doubtless, the seed of the parasite was introduced with peat.

PHYLOXERA REGULATIONS AT THE CAPE.—We are pleased to see that the Cape Government has at last repealed the vexatious and useless restrictions on the importation of plants, other than Vines. We have protested against these absurd rules up till now in vain, so that it is pleasing at length to see some signs of the abatement of these mischievous enactments.

"ONE AND ALL GARDENING."—This is described as being a "popular annual for amateurs, allotment-holders, and working gardeners," and certainly for the price asked (2s.), is well worth the consideration of all these classes. It is edited by Mr. EDWARD GREENING, and published by the Agricultural and Horticultural Association, Agar Street, W.C.

"GARDENING FOR ALL."—This handbook, by JAMES UDALL, with an introduction by the Right Hon. Viscount CONHAM, is issued as a Worcestershire Technical Instruction Committee Manual. Its pages are devoted to the consideration of soils, crops, and small collections of flowers, fruit, and vegetables; and the reliability of the information given is quite to be depended upon. It is true that there are now-a-days many books upon gardens and gardening, but it is also true that the reading and gardening public is ever increasing. To meet their requirements, here

is yet one more book which, for clearness of style and plainness of the illustrations, may be commended to their notice.

POTATO EDUARD LEFORT.—The well-known firm of MM. H. VILMOIS, ANONIEUX & Co., are distributing a variety of Potato which deserves attention from the gardening world, not only for its high cultural value, but also as being the product of grafting the variety *Imperator* on the early *Ashleaf* (*Marjolijn* of the French). This is certainly the first instance of a hybrid having been obtained in this manner, which combines the peculiar good properties of the stock and the scion. The tubers are of middle size, round in shape, and keep in good condition for a considerable period. The flesh is yellow, firm, mealy when cooked, and of good flavour. It is an early ripening very prolific Potato, with but little haulm. The raiser is M. LEFORT, of Strawberry fame. *Wiener Garten Zeitung.*

THE APPLE-BLOSSOM WEEVIL.—Mr. F. V. TUEBOLD has placed fruit-growers under an obligation by printing, in a concise form, the account of the appearance and manners and customs of the destructive insect known as *Anthonomus pomorum*. The pamphlet may be had on application to Mr. TUEBOLD, at the Agricultural College, Wyo, Kent. The application of kerosene emulsion before the flower-buds open is recommended, and it certainly has an advantage over very poisonous substances, such as London-purple or Paris-green. Mr. TUEBOLD calls attention, nevertheless, to a new insecticide in the form of arsenate of lead, the mode of preparation of which is detailed in the pamphlet before us. The cost is not greater than 4s. per 100 gallons, and we are told that it is "most successful in regard to leaf and hatching larvae, and is well worth a trial by all fruit-growers."

ALTERNATIONS OF GENERATION.—We alluded to this subject in our last issue, and had we received it in time we should have mentioned a paper of M. HENRIK HESSELMAN on the "Formation of Floral Leaves from the Scales of Bulbils in *Lilium bulbiferum*;" in other words, transitional forms between the scales of the bulbils and the parts of the flowers. The paper is in Swedish, but there is a summary in German.

LORD ROSEBERY POTATO.—Several of our northern correspondents have kindly furnished us with information concerning the origin of Lord Rosebery Potato. It is stated to be a seedling from Graupian—a much-esteemed Scotch variety, and it is one of the finest round coloured Potatoes grown. Messrs. G. BRUCE & Co., Aberdeen, catalogue it.

COMING EXHIBITIONS.—Schedules have been received from the following Societies:—

ROYAL BOTANICAL AND HORTICULTURAL OF MANCHESTER, for exhibitions to be held on the following dates:—June 4 to 10, and July 10. The first of these is the usual Whitsuntide fixture, for which there are forty-one classes. Most of the flowering and foliage plants in season at that time are scheduled. The exhibition on July 10 will be one of Roses, and in conjunction with this a cottagers' competition will take place.

THE RATH FRUITS FETE AND BAND COMMITTEE have arranged for a Rose and Begonia show on Thursday, July 8, and a general exhibition of horticultural produce on September 1 and 2. Efforts have been made to make each of these a success.

LEEDS FLOWER SHOW AND GALA.—This event is to take place in the Healdingley Athletic Grounds on Wednesday, July 7, and two following days. The schedule includes seventy-two classes of varied and comprehensive character; Orchids and groups of miscellaneous plants are specially encouraged.

WEST OF ENGLAND CHRYSANTHEMUM.—The annual exhibition is to be held in the Guildhall, Plymouth, on Tuesday, November 2, and following day. The schedule includes classes for fruits and vegetables, and, in addition, many special prizes are offered for similar produce. The *Chrysanthemum*, however, will create three-fourths of the show.

THE FEATHER-WEIGHT BOUQUET.—We remark in a pictorial list of floral designs, issued by Messrs. E. S. WILLIAMS & SON of Holloway and Piccadilly, a novel kind of bouquet, consisting of long sprays of Asparagus, to which slender, pendent sprays of flowers are attached. Providing the flowers are of a suitable kind, a bouquet of this sort has an elegant appearance; and, being but a few ounces in weight, it imposes no arduous efforts on the part of the lady to keep it in her hand.

APPLES FROM THE ANTIPODES.—When in February last we noticed the arrangements for the supply of Tasmanian Apples to this market, the limit was in the vicinity of 100,000 boxes—that limit has been exceeded already, and to-day we have the following from the officials of the P. & O. S. Co.:—By the Orient Co.'s steamer *Ophir*, 16,000 boxes;—by the P. & O. Co.'s steamer *Ballarot*, due about June 2, 25,000 boxes; and by the Orient Co.'s steamer *Ontawa*, 5300 boxes.

ROYAL BOTANIC SOCIETY.—Owing to the late cold weather having kept back the flowers, the show of the National Tulip Society, which had been announced to take place in the Gardens on May 5 and 6, has been postponed to the 12th and 13th.

PUBLICATIONS RECEIVED.—*The Canadian Horticulturist* (published by the Ontario Fruit Growers' Association, Grimsby, Ontario), April.—*Favourite Flowers of Garden and Greenhouse*, vol. iii., No. 34.—U.S. Department of Agriculture, Division of Entomology, *Some Little-known Insects Affecting Stored Vegetable Products*, by F. H. CHITTENDEN. Among the contents of this useful *Bulletin* are articles on:—“The Dried Currant-moth (*Ephestia cahrirtella*),” “The Chocolate-moth (*E. elutella*),” “Notes on Grain-beetles of the Genus *Silvanus*,” “Granivorous and other Habits of Certain Dermestidae,” “Weevils that Affect the Seed of the Cow-pea,” “Development of the Common Bean-weevil,” “A Little-known Grain-weevil (*Caulophilus latinus*),” “On the Occurrence of the Grain-moth,” “Invasion of the Coffee-bean Weevil,” “Parasites on Flower and Meal-moths,” and “A Foreign Parasite of the Grain-weevil.”

CYPRIPEDIUM LAWRENCEANUM.

CYPRIPEDIUM Lawrenceanum is usually “stemless”—that is, the stem is very short, but occasionally the stem is developed, and the result is, that the leaves are closely packed in two rows, as shown in our illustration (fig. 99, p. 291), taken from a specimen sent us by Messrs. Hugh Low & Co. In this plant there were as many as four growths (A, B, C, D), the latter bearing the flower-stalk.

HOME CORRESPONDENCE.

STRAWBERRIES AS BIENNIALS.—I noticed recently at Droppore that Royal Sovereign, treated as above on a warm border, was, on April 15, throwing up strong trusses of bloom from plants put out early last autumn. They had not been specially layered, but were lifted from the bed and planted out as soon as the border could be prepared after early Peas had been removed. Not only were the bloom trusses strong, but the foliage was strong also. Nettle was good treated in the same way, but the other variety was stronger and more promising. The plants are put out 12 inches apart each way, and, of course, a rod of ground taking some 250 plants, carries not only a great quantity of fruit, but very fine fruit also. The entire border is yearly equally divided between early Peas and Strawberries, the cropping being alternated with the very best results. A. D.

APPLE, BRAMLEY'S SEEDLING, appears to vary considerably in its fruiting properties, and a tree occasionally becomes perpetual cropper. For many years a large tree at the place failed to fruit till I removed it to a somewhat shady corner, when it grew away rapidly, and now produces heavy crops regularly. The fruit does not keep after Christmas. Young trees on the Paradise stock fruited at four and five years' old. It appears to be a fine cooker, but very sour. The two best Apples at present are Royal George, a variety with very distinct growth. It is described as follows in Melnotus's *Practical Gardener*, fruit large, oval, yellow and green, flesh firm and sugary, beautiful fruit, keeps well, is in eating from January till June. Tree handsome and a great bearer. We are exhausted the supply of this variety to-day, and are now depending on the best Apple we grow here, which is Newton Wonder. This is a very fine Apple, and is useful for eating as for baking, though it grows to a size too large for dessert, its flavour and fine appearance are appreciated. *G. Dolas, Weynton Hall Gardens, Wicksworth, Dorsetshire*.

—This variety is not in high favour at Droppore, because in bush form it is not so fruitful as are many other equally good and useful varieties. No doubt the variety is best at home planted in orchards, where it can grow strong for several years, until its immense energy being somewhat exhausted, it commences to bear, and thus becomes a very profitable variety. For bush culture Lane's Prince Albert and Wellington seem to be of the best for producing late, long-keeping fruit, and after all it is doubtful whether there exists of late varieties any two others that excel these for home uses or for market sale. Whilst at Droppore, many of the best varieties show already great prospective productiveness, the few gross growers show that they would be better on free stocks in thin orchards. A. D.

—Both this Apple and Lane's Prince Albert have elicited much attention in East Anglia and other parts of England and Scotland, when exhibited at Technical Instruction Lectures. They are of good size, high colour, and good quality. Should Mr. Merryweather have one or two to spare, I should be

glad if he would send two or three of each to 12, Pettes Row, Edinburgh, when I would duly and truly report upon them. *Apogon* of Apples, I had a curious case of an almost entire absence of colour in a fine sample of a Bismarck at one of my recent Lectures on Technical Education. Whereas the last I had previously exhibited, a *fac simile* of which was painted by my wife at the time, was more fully coloured than a Blenheim Orange. And yet the almost colourless Bismarck hailed from Herefordshire. D. T. Fish.

TRANSPLANTING BRACKEN.—Some years ago I had a large quantity of this Fern sent up from Haats to mix with rock-work in decorating a bank. The hard sand in which Bracken and Ling had been growing, admitted of blocks being cut of about a foot square and 8 inches thick. These were loaded into carts and railway-trucks with facility, and were easy to haul in forming the bank. It was interesting to find that in time Brambles, Scotch Fir, Beech, Birch, and Oak, as well as the Ling and Bracken, appeared, and made themselves at home, and the rock-work bank was soon clothed with verdure of a varied and pleasing wildness. Your distinguished correspondent, Mr. D. T. Fish, pp. 277, 278, recommends masses of Bracken and soil a yard square, and by implication a foot or more thick. The weight of these would be about 5 cwt. each! On a large scale, the best implement for breaking up Bracken is a strong plough, as long pieces full of surface-rhizomes can thus be obtained. I agree with Mr. Ghring, (p. 280), that the best time to transplant Ferns is when they begin to grow in the spring. *W. Roupell, Strathain Hill*.

COMMEMORATION PROPOSAL FOR A ROSE-DAY.—I saw in some paper lately a list of all the proposals which had been made to commemorate the Queen's Diamond Jubilee. They ran up into the hundreds, and were full of fun, fancy and folly, though the fun was usually unconscious. Notwithstanding the portentous number of suggestions, I am going to make another. It is a simple and sentimental proposal for the decoration of our persons on June 22. I think the British floral emblem, the Rose, should be worn by everybody on the Celebration Day. The Rose-rop will be in all its glory at the end of June, and no one need be without one who has a penny to spend. I further suggest that here, from June 22, shall be always known as “Rose Day,” in honour of England and good Queen Victoria. (N.B. All pirates of this idea are hereby warned that it is the sole property of “Alter Ego.” Yes! I think “Rose Day” ought to come. As the Post Laureate says in his best prose work, *The Garden that I Love* (p. 92):—“The Rose is the typical flower of the world over, and the mind cannot get away from its representative personality. Withal, in most gardens, the Rose enjoys but a brief reign, much briefer than that of many another flower, but so long as it blooms in profusion, it throws into the shade all other pretenders.” Just so, “Rose Day” would throw all other celebration days into the shade. The Rose is a Royal flower, and should be used on such a truly royal and national occasion this year, and for all time. *Alter Ego*, in “*Church Family Newspaper*.”

VOLES AND MICE.—When you kindly opened your columns to us on this subject, our main object in writing was to ascertain if any other nurserymen or growers in quantity of young trees had had their stocks damaged by voles this season similar to ours, and gaining this point meant the matter to drop. But really Mr. Simpson, in your issue of April 24, has distorted our remarks on the subject to such an extent that we cannot refrain from replying. First, we never said voles and mice were not a distinct species, only that they were generally described as “field mice.” Also that voles could climb and get at Scots Fir buds. Second, the 4-foot Scots mentioned in our initial article were words from Mr. Dunn of Dalkeith's letter, as having occurred in his experience many years ago, and not our words. We simply stated in our second article, that stiff-growing two-year transplanted Scots Fir about 15 inches high growing in nursery rows, such as ours were, was no obstacle for the voles to get up, and this we still maintain whether Mr. Simpson doubts it or not. *Living and Mather*.

VIOLETS.—Noting your capital article in the *Gard. Chron.* of April 17, and the characteristic sketches of Viols, allow me to mention that Princess of Wales (Princesse des Galles of the Continent) is far and away the finest variety. The Viols do not succeed

in our town, owing to the smoke, and we therefore cultivate them in the country, where we find California to be of no value, being weakly in growth, and sparse in flower; while Princess of Wales is glorious in September, and flowers again freely in April; and possibly in warmer districts it would blossom all the winter. In autumn its flower-stalks approach 1 foot in length, and the foliage is like a *Col's-foot-leaf* for size. Unless the newer kinds improve under culture, they will not be of much service. With *Lee's Victoria Regina* and *Welliana* for winter blossom, *Lee's Odoratissima* for a fine bloom, and the Princess, we can make sure of a constant supply of blossoms, except during periods of frost and snow. *George Bangard, Maidstone.*

As a large grower of Violets for many years, and a lecturer in the Royal Botanic Gardens, Edinburgh, on April 9, on "Sweet Violet in Plum and Profit," I was specially interested in your very instructive article in the *Gardeners' Chronicle* on the 17th. Perhaps, under the circumstances, you will permit me to direct attention to a few of the, of course, wholly accidental coincidences and contrasts between the article and the lecture, as well as to express a practical opinion of the value of some of the best varieties, new and old. Leaving out the plant of the newest *Viola odorata sulfurea*, and the enlarged addition of Princess of Wales, seven varieties were illustrated on pp. 27 and 219 of the *Gardeners' Chronicle* for April 17; seven was also the number of the plants, and of bunchets of bloom, with which the kindness of a most successful East Anglian Violet-grower enabled me to illustrate my lecture with fragrant and beautiful object-lessons. But while your illustrations were all single, five out of the seven object-lessons at the lecture were double. Another contrast—your illustrations were mostly and necessarily new; those at the lecture were chiefly old. The double varieties at the latter were *Marie Louise*, *Comte de Brasza*, *De Parme*, *Double Victoria Regina*, and *Neapolitana*. The singles were *Welliana* and *Russian*. I also noted in Professor Balfour's private garden a fine mass of the all-too-rare single *Neapolitan Violet*, one of the sweetest and most chaste of them all. At the close of the lecture in the Botanic Gardens on the 9th, the first question asked was one concerning the character and conduct of cleistogamous Violets. The subject may be said to form the two first and more important paragraphs in the *Gardeners' Chronicle*. It came to the lecturer in quite a different form. Thus: "Pray, sir, can you tell me how it is that a bed of *Neapolitan Violets* in my garden has not bloomed for seven years, though it seeds plentifully every year?" The latter clause revealing the presence and potency of cleistogamous flowers, if a Violet with little colour and less fragrance, that hugs the ground under the leaves, instead of rising modestly into the air and saturating its environments with fragrance, deserves the name of flower. The answer as to cure of barrenness was, more light, less shade, moderate feeding, and annual division into single crowns or stubby single runners. Can it be possible that the theories you lay down, viz., that cross-fertilisation secures variation, and that close fertilisation ensures stability of character and absence of variation, explain the stability of the *Neapolitan Violet*. Possibly there are few Violet growers that have not been puzzled with these curious abortions, which are specially prevalent among *Neapolitan Violets*, which is probably the oldest of all existing varieties. Another curious point in relation to these unformed spoilt Violets is that they are seldom or never seen among the thousands and tens of thousands of Violets, grown afresh from crowns and rounded, pointed runners, every year, for blooming at distances of from 9 inches to a foot asunder, kept clear of runners and of weeds, and fully exposed to the light. Special care should be exercised in selecting runners of *Neapolitan Violets*, avoiding not only cleistogamous plants, but all with sharp, narrow-pointed runners; and by careful selection in broad, mechanical lines, strains may be vastly improved, and the produce and size of flowers doubled or more. No doubt the original form of the *Neapolitan* was single. In colour, this and the double have not been the same. The history of the so-called white *Neapolitan* is of doubtful authenticity. As to the best varieties, permit me to make a note or two on a few of the new ones, as well as the old sorts of Violets. As to the *odorata sulfurea*, its colour will almost certainly prevent its popularity. Just as surely as a Rose by any other name would not smell as sweet, so neither will a Violet of any other colour than blue or purple. Hence single and double red have made but scant progress, and even white has never

come up to purple in popularity or profit. Hence this dull sulphur-coloured Violet, unless very liberally filled with fragrance of which nothing is said, is not likely to win its way to fame or fortune. The Princess of Wales is almost too large, of good colour, sweet odour, but bad form for a sweet Violet. In fact, as the natural flowers and your illustration proves, the flowers are those of a "Violet," and not of a "Violet." And notwithstanding its substantial merit, and its name appealing to our loyalty in this Diamond Jubilee Year, the size and especially the form of this Violet will probably swamp or fetter its popularity. California may be described as a monster Czar, with giant-like leaves, leaf-stalks from 9 inches to a foot in length; flowers intense violet, from 1½ to 2 inches across. I have met with it in various places, and not once very profusely flowered. It seems almost too vigorous for a Violet, especially when we hear in advance that though it is unquestionably hardy, it is unquestionably better for protection. Of other singles *Welliana*, which has often been described correctly as an improvement on *Victoria Regina*, and *odoratissima*, *Devoniana*, *Victoria*, single *Russian*, and *London*, should find a home in every garden. For double

with the majority of the Floral Committee, and that plants which would be of the greatest interest to many of the amateur visitors to the Drill Hall are passed over in favour of those likely to have a large and ready sale. The late frosts have hurt flowers much; we had fine clumps of *Epigae repens* and *Shorita salicifolia* covered with bloom, but one night's frost browned almost all the flowers, and I fear many Plums and Pears have been touched. *George F. Wilson, Weybridge.*

A plant of this species blossomed here about three or four years ago. It had for a very long time been cumbering the ground, and I thought of throwing it away as being altogether useless to me. Instead, however, of adopting this rash expedient, I picked out for it what I considered was the worst place in this garden, and I planted it in some very rough soil under an old Fig-tree. There it is now, but it has never blossomed again. I thought the move was responsible for its better behaviour, but it may have been only a question of age, as Canon Ellacombe says. *H. Ewbank, St. John's, Ryde, Isle of Wight.*

DAPHNE MEZEUREUM.—The writer of the article, "Tree and Shrubs," in the *Gardeners' Chronicle* of April 3, in his comments on the habits of the two species of *Daphne*, *Mezeureum* and *laurena*, mentions that the former does not propagate itself in his district by seed, while the latter does. It might be interesting to him, as well as others, to know that the *Mezeureum* in the garden here multiplies readily by seed, so much so, that whenever a plant is wanted, one has nothing to do but to go into the shrubberies or woods around and choose one. Its seed is most likely disseminated by birds, probably blackbirds and thrushes in particular, which devour the berries and void the seeds, thus effecting the distribution of the plant. *J. Parkin, Blithwaite, Carlisle.*

CAMELLIAS.—On p. 249 "A. D." remarks that these beautiful shrubs might be grown in the open, south of London, if provided with suitable soil. For the last thirty or forty years a grand plant of *Camellia Sasanqua* has been growing in the open near here. Hard weather does not affect it, excepting the sharp frost of a few years back, which followed a mild weather, and while the plant was aglow with flowers; and even then, only those that were exposed got spoiled. The plant is about 12 feet high, and 6 feet in diameter. All through the period from the beginning of February to early in March, it has been a delightful feature this year. Its flowers appear from four to six weeks before the *Cydonia japonica*, according to the season. Other varieties of the *Camellia*, especially *Duchess of Northumberland*, have been grown in the open upon the same border, but none proved so entirely satisfactory as *C. Sasanqua*, *Laurels*, *Laurustinus*, *Bays*, and many reputedly hardy subjects have been much injured by frost, but the *Camellia* was unharmed. The plant faces the south, and yet the sun has no injurious effect upon it. No fresh soil or manure of any kind has been afforded it, so far as I can remember. *A. P.*

FROM THE EMERALD ISLE.—We have not had such a cold, wet, and sunless spring in Ireland for the last forty years, according to our best local meteorologists—and then a hot and fertile summer followed it. I hope the same may be the case this time—a warm and dry late summer and autumn being most desirable in this country. At Newry the spring flowers are very fine, and there is a great show of fruit-tree blossom everywhere. Smith has a very fine lot of early Dutch Tulips now in bloom, mostly home-grown. It is curious to notice that the home-grown Tulips (Dutch variety) are seven days earlier, and one-third taller than are those of some varieties as imported direct from Holland last autumn and grown side by side with those grown here for two or three years. *F. W. B.*

ABIES BRACTEATA.—The measurement of the tree here at 3 feet from the ground is 8 feet 2 inches; spread of lowest branches, 32 feet; but I can see no signs of any female cones, although I have examined the tree with a glass. It is now eight years since it bore female cones, and we quite expected it to show some this spring after the hot summer. *Frank Harris.*

TREES IN HEDGEROWS.—Your recent leader has struck a note that has been frequently sounded, and so far as I have observed, there has been no discussion on the subject that has had any material effect. I refer to the planting of trees in hedgerows. There is undoubtedly much to be said in favour of the practice, when the dreary highway, with its unbroken stretch of hedgerows, is being traversed under the influence of July sunshine, at which time the shade

FIG. 99.—*LYTHRUM LAURENCEANUM*. (SEE P. 290.)

Violets the following are pre-eminent, *Marie Louise*, *Comte Brasza*, almost the only white Violet really worth growing; *De Parme*, *Neapolitan*, *Victoria Regina*, *Mlle. Bertha*, *Barron's* *syn. Victoria*, fully scented, beautiful indigo blue; *King and Queen of Violets*, fine and striking for growing out of doors. Finally, will any practical Violet grower kindly define the difference in the following Violets, *De Parme* and *Lady Home Campbell*, *Marie Louise* and *New York*, and *Venice*? Also kindly name a better all-round Violet in the open or under glass than *Marie Louise*; also name with tolerable certainty the double-flowering or perpetual single Violet of certain parts of England and Ireland, and what relation these have to the Violets *De quatre Saisons* of the environs of Paris. *D. T. Fish.*

LILIUM THOMPSONIANUM, ETC.—After reading my friend Canon Ellacombe's note in the *Gardeners' Chronicle*, p. 277, I think that it may be of interest to state that a plant of *Lilium Thompsonianum* in good bloom, sent to me by Mr. Leitchlin, was shown before the Floral Committee many years ago. Mr. Leitchlin then told me the secret of flowering it was the taking off the numerous small bulbs which it forms, and which weaken the plant. Acting on this hint I bloomed this Lily well in an orchard-house, and once out-of-doors. I quite agree with Mr. Elwes at p. 256, that trade considerations weigh too much

of a tree would be most welcome, and when the artistic effect also is considered, another strong vote is recorded in its favour. The economic aspect has also been advanced to further the object in the planting of fruit trees of such varieties that would be likely to succeed in those positions. The latter part of our continental countries, benefiting the district to a considerable extent. Where the hedgerows are under the supervision of the County Council, such plantations would be of great advantage, as examples for their instructor to demonstrate upon, as the position they occupy would be such that even those who run, or rode either, could read. But he would be a bold landlord who would attempt the experiment on an average British hedge. When an occasional plant of Holly in a high way is to a skeleton some weeks before Christmas, it is very doubtful whether an Apple or Plum would be permitted by "travellers" to perfect its fruit for the benefit of its rightful owner. I do not mean to infer from this that the majority of roadsters take that which belongeth not to them, but those of us who have schoolboy recollections remember the Eden temptation there is in an Apple within reach of a stone's throw, whatever the variety may be. But I think the practical aspect of the case would be its strongest condemnation. Undoubtedly the chief object of a hedge is to fence off the property it encloses. Now, the more perfect the hedge, the better it fulfils that object. When trees are planted at intervals along the hedgerow, the growth underneath those trees is invariably weak and flimsy—the very opposite of what it should be. Holly is considered by authorities from the time of Evelyn until now to be the best subject to plant under the shade of trees—and undoubtedly it is; but I have never noticed it in such a condition that it could be termed a perfect fence. Cattle and horses quickly find out the weak places, and it is needless to dwell on the deprivations they make in a very short space of time, besides the many other inconveniences that ensue from a gap in the fence. Now is this the only drawback to the practice, for even the most casual observer must have noticed in passing how greatly the land is robbed of the nourishment which should be utilised by the crops for a considerable radius from the tree. Elms have a notorious reputation in this respect, a striking instance of which was observed in a field of Potatoes last season not far from here. The field throughout had been well manured and cultivated, producing outside the radius referred to a very good crop, but within this space the crop did not pay for the labour of lifting it, a result which had been fully predicted by many who saw the foliage growth made during the season. The writer knows well a good example of fruit-tree planting in hedgerows. The hedge divides two fields, and is a considerable distance from the highway, so that the trees have escaped the mutilage so noticeable in fruit-trees growing close to the road-side. In many places, underneath the trees the fence exists only in name, and wherever the umbrellas of branches is spread, there is no live hedge that could honestly be called a fence. The fruit they produce is, as might be expected from the position they occupy, very inferior, possessing no marketable value, and therefore could be made into cider. The commercial value of this commodity cannot be very great, as I have noticed in seasons when the Apple crop has been plentiful, that a considerable quantity of fruit is left to rot on the ground, or to be eaten up by the stock grazing around. A combination of fence and fruit is, in my opinion, a very doubtful arrangement, and I cannot agree with the idea of spoiling a good hedge for the satisfaction of producing inferior fruit. *J. MacDonall, Clanna.*

SOLANDRA GRANDIFLORA.—The figure of *Solandra grandiflora* in your last issue is very perfect, and shows a feature in the margin of the flower, part being filled and the other plain. It may be of interest to some of your readers to know how it has been grown and flowered here. We never allow late staking to result in high night temperatures. The fires are made up before all hands leave the garden at half-past five, and earlier on Saturdays and Sundays. I attribute our success in flowering this and other mountain plants partly to this practice. Our plants have been so treated for some 10 years. *Solandra grandiflora* is grown in an 8½-inch pot, 9 inches deep. It is a bush, 3 feet high, the longest branch being 4 feet long. It is potted in fibrous sandy loam, and stands over a shallow tank of water built over the fire. It is allowed to root through the bottom of the pot into the water when

making good or flowering. After flowering, short-jointed growth is made, and then it is gradually allowed to get dry till every leaf falls and the plant slightly shrivels. It is then shaken out and re-potted, and put into brisk heat. The buds soon form, growing slowly, but developing largely, till we are rewarded with a most delicate perfume as the flowers slowly expand. The new plant has a vigorous healthy appearance. I am hoping to flower it twice in the year, as we do *Clerodendron Balfourianum*. I have treated *Allamandas* also as bushes, using only one stick. I have seedling *Allamandas* that flower in this way, without any support, but they are of no value, being small, but very floriferous. *George Bales, Haydon Hall Gardens, Devonshire.*

SOCIETIES.

THE ROYAL HORTICULTURAL.

APRIL 27.—An ordinary fortnightly meeting of the various committees was held on Tuesday last in the Drill Hall, James Street, Westminster. In bulk, the exhibits were considerably less than on the previous occasion, and may be described as average in extent rather than extraordinary, like several of the exhibitions held during the present spring. The principal features in the display were Orchids and Roses, there being fine collections of each. Of the latter, there were plants in pots, and numerous and diverse. A few were again shown, and what we may expect to be the last flowers of Narcissus during the present season. As will be seen below, several collections of these were quite noteworthy. A few awards were made to plants of interest, but these were not numerous.

Floral Committee.

Present: W. Marshall, Esq. (Chairman), and Messrs. C. T. Druce, H. B. May, H. Heriot, R. Dean, Geo. Stevens, J. S. Loudon, J. van Jennings, J. F. McLeod, R. B. Lowe, H. N. Leonard, Chas. Jeffrey, J. W. Barr, Chas. E. Shei, J. D. Pawle, D. B. Crane, H. J. Jones, H. J. Gubbish, Chas. Dick, R. Turner, Geo. Paul, T. W. Sanders, Owen Thomas, and Thomas Peel.

A collection of hardy plants, from Mr. THOS. S. WAVE, 11, Victoria Terrace, Richmond, included several species of *Primula*, notably varieties of *P. Sieboldii*, also *P. pendulata*, &c.; *Gentiana scabra*, *Trillium erectum*, with dull crimson flowers; several species of *Saxifraga*, *Lilium Browni*, *Cypripedium pubescens*, *Anemone fulgens* (an exceptionally bright-coloured variety), *Narcissus Bulbosidius*, &c. (Silver Flora Medal).

A few blossoms of *Tulipa Greigi*, from Messrs. R. WALLACE & Co., Kilburn College, Colchester, were exceedingly bright.

A group of Ferns and ornamental Coleus was shown by Mr. H. B. MAY, Deyson's Lane Nurseries, Upper Edmonton. The varieties Golden Gem, Crimson Gem, Mrs. Evans (scarlet leaf, edged with gold), Mrs. Dickenson, Gloriosa, and others were very pretty, and each was represented by three well-grown plants of moderate size (Bronze Banksian Medal).

A bunch of excellent flowers of the Princess May variety of *Mahonia Canadensis* was shown by Mr. C. TURNER, Royal Nurseries, Slough (Bronze Flora Medal); also a plant of *Richardia Elliottiana*, with a richly-coloured double spathe. An Award of Merit was recommended to Nasturtium Mrs. Sanderson, shown by Mrs. SANDERSON, The Mount, Eding; about a dozen plants were exhibited, the habit being quite dwarf, and producing numerous erect flowers of rich intense crimson.

Messrs. Wm. Carrington & Sons, Highgate Nurseries, London, made an excellent exhibit of varieties of *Azalea mollis*, including *A. m. sinensis*. The plants were interspersed with a few decorative species, and a fine effect was produced (Bronze Flora Medal).

A group of miscellaneous plants from Messrs. JNO. PEECE & SONS, Ropell Park Nurseries, Norwood Road, S.E., (Silver Banksian Medal).

Another group of miscellaneous stove and greenhouse plants was one from Messrs. J. LAING & SONS, Forest Hill, London, S.E. It contained many excellent decorative species in fine condition. They also exhibited some plants of *Streptocarpus multiflorus* perfect, a strain producing showy white flowers with purple-velvet marks in throat. A pretty *Gloxinia* named Lady Elridge may be mentioned also (Silver Banksian Medal).

There were three large plants in flower of *Arctostaphylos* from Mr. DOWNING, Esq., Holmwood, Chesham. The plants were again shown in considerable quantity by Mr. GEO. MORSE, Canterbury, and the varieties Catherine Mart, General Jacquemont, and the Bride, were represented in particularly fine manner. Many other varieties in less numbers were capitally shown, including a few with long

stems possessing bright healthy foliage (Silver gilt Flora Medal).

Mr. W. DEWAX, Juyning's Nursery, Waltham Cross, London, N., made a good display of Rose blooms, and also of plants in pots. Of the latter, there were numerous varieties represented by small plants, and there were several large boxes filled with blooms of diverse varieties (Silver Banksian Medal).

Mr. FRANK EAST of the Braikwick Nurseries, Colchester, made a group of Roses in pots upon the floor near the entrance door. The plants were young and dwarf, in capital health, and possessed of good foliage. The varieties included were fairly numerous. The following were conspicuous amongst them: *Cadillac* Christy, Marie Baumann, Anelle Bernadine, Shirley Hubbard (a pretty little yellow Rose), Mrs. Harkness, Mrs. R. G. Sherman Crawford, Chas. Lefebvre. Varieties of the *Polyantha* type skirted the group (Silver Flora Medal).

Messrs. PAUL & SONS, Chesham, showed a group of Roses in pots, a few meritorious *Hippocrasiums*, and several species of hardy plants in flower. Also a plant of *Moronea pendula*, or a weeping variety of the White Mulberry. This latter was recommended an Award of Merit, and a Silver Flora Medal was awarded to the group.

The genus *Primula* was represented by a collection of *Alpine Auriculas* and varieties of *P. Sieboldii*, from Mr. CHAS. TURNER, Slough. Slough, among the former being some newer sorts raised at Slough. The gold centre is easy to get in the *Alpine Auricula*, and the nearer it approaches a deep bright gold, the greater is the contrast with the marginal colours. A few of the leading varieties were Fred Kington, of a wing group, which has a fine show of bloom; the ground colour maroon, shading to deep lilac-rose; the pip flat, and circular, and a fine exhibition variety, though a little late in blooming. A plant of this variety was submitted to the Floral Committee by Mr. R. DEAN, Eding, and an Award of Merit was recommended to the gold-centre section were—*Silvia*, local maroon ground, with slight shading of crimson; John Bewick, having a maroon ground, broadly shaded with bright crimson; Mr. Watts, in the same way, but the yellow-centre deeper—this is a fine variety, having a symmetrical, flat, smooth pip; Joseph Adams, the centre bright red, shading to each side of the corolla, shading to rosy-salmon—a variety of considerable refinement; Comet, bright gold, slight dark ground, with broad edging of rosy-salmon; W. L. Walker, pale gold, the maroon ground shading to rosy-lilac-like, flat pip of high quality; Albert, having a broad, dark ground, with broad edging of rosy-salmon; and Adventure, having a dark ground extending nearly to the edge, with a slight wavy shading of lilac.

The white centre is much more difficult of attainment, as so very few varieties open white, and then maintain it bright and clear. Some of the white varieties do not have a pretty appearance, while the marginal colours are bright and effective. Others open pale yellow in the centre, and bleach to white; but in the case of such a variety, the truss has a confused appearance, as pips have different tinted centres, according to their development. The purest and most lively white centres are generally associated with lilac, violet, mauve, or purple in the marginal colours, though the white centre is sometimes found in combination with a crimson shaded margin. Three of the best of the newer white-centred *Auriculas* are to be found in Wimpoff, Mrs. Harry Turner, and Countess, all having dark ground colours, and a pinkish or rosy-purple centre. Others are Dora, with dark blotches shading to pink, and deepening to rosy-lilac, fine pip; Countess of Stamford, black ground shading to deep rose-rose; Duchess, cream centre paling to white, dark ground shading to lilac; and Pantaloon, a charming variety, black ground, distinctly lined with lilac rose. Mr. R. DEAN had a white-centred flower named J. W. Wilkinson, the lilac shading on the margin being much reticulated.

Mr. TURNER had several plants of *P. Sieboldii* in variety, each pan being filled with small plants in pots. The darkest was Victor, bright yellow, each rather later in flower than Ruby Gem, Harry and Arthur, pale soft rose, Polly and Mrs. Crossland, of still softer tints; Mrs. Ryder and Fairy Queen, bluish; *Alba grandiflora* and Queen of Whites, the best whites. Beautiful and easily grown as are the varieties of *P. Sieboldii*, yet they do not appear to take the public fancy so much as their deserts (Silver Flora Medal).

Messrs. JAS. VERRIN & SONS, Royal Exotic Nrsry, Chelsea, were awarded a First-class Certificate for a new hybrid greenhouse *Rhododendron*, named R. x superlatissimum. It has large white blossoms, exceedingly fragrant, of the same type as Princess Alice or Lady Alice Fitzwilliam, and of the same parents as the *Rhododendron*. Pretty plants of *Capressus Lawsoniana* var. *versicolor* and *C. L.* var. *uliformis* were noticed, and a few excellently grown and finely-flowered plants of *Carnation Winter Cheer* and *Streptocarpus Polyantus*, with numerous rather small *R. mayne* flowers, produced by the Polyanthus Messrs. JAS. VERRIN & SONS, also exhibited plants in flower of *Cytisus precox* (standard), *Andromeda speciosa* *casuilloide*, *Eschola grandiflora*, and *Cydonia Muhl.*

A few well-grown plants of *Boronia serotina* and *Epimedium *Baueriana* variegata* were exhibited by Messrs. W. BLYTHE & SONS, Haresfield Nurseries, near Messrs. JAS. VERRIN & SONS. An extraordinary variety of Lily of the Valley, with large inflorescences, and is of uncommon size, was shown by Messrs. LANTON BROS., Bedford.

Messrs. BARR & SONS, King Street, Covent Garden, made a large display, with Tulip Buds of many diverse types.

Several species also were represented, including *T. elegans*, *hery-erioson*; *T. e. variegata*, *T. fulgens*, *T. acuminata*, a species with extraordinary attenuated petals; *T. retroflexa*, yellow; *T. viridiflora* *procox*, &c. (Silver Flora Medal).

Messrs. J. JAMES & SONS, Farnham Royal, exhibited a few crosses of the garden *Cineraria*, with *Senecio cruentus*, which were submitted afterwards to the inspection of the Scientific Committee. No. 1 was the result of a cross between *S. cruentus* and the pollen of an ordinary *Cineraria* Nos 2, 3, 4, and 5 were the result of crossing this hybrid (No. 1

erect stout stems, to the number eight or nine flowers upon each. A slight tinge of lilac could be observed upon the exterior of the umbel.

Mr. H. B. MAY, Dyson's Lane Nurseries, Upper Edmonton, showed five varieties of the Fern, *Lomaria ciliata*. A distinct variety, named Major, was recommended an Award of Merit; and another one of very pleasing appearance, named *Gracia* a First-class Certificate.

Mrs. POWYS, Cornwall, showed *Myosotidium nobile*, from the open ground. It is the only species, and belongs to

Probably, in consequence of the Hamburg Show, there was a smaller display of Orchids than usual, but the show made was bright and interesting. *Odontoglossums* formed the chief feature, and of these WELBORE S. ELLIS, Esq., of Hazelbourne, Dorking (gr., Mr. Darrell), and R. BROOMAN-WHITE, Esq., Ardistrach, Garschoed, two amateurs famed for the cultivation of *Odontoglossums*, had good groups of these favourite flowers, the former gentleman securing a Silver Flora, and the latter a Silver Banksian Medal.

Mr. WHITE's group contained the only plant which was

FIG. 100.—MYOSOTIDIUM NOBILE.

(Shown at the Drill Hall, on Tues.-day, April 27, 1897, from the open ground, in Cornwall. See Report of Royal Horticultural Society's meeting on this page)

with *S. Heritieri* No. 6 of *S. Heritieri* with pollen of *S. cruentus*. No. 3 had white flowers, with foliage similar to that of *S. Heritieri*. It is pretty, and would make a useful greenhouse plant.

Some samples of metallic labels were submitted by Mr. J. A. HORRILL, 295, Southampton Street, Camberwell, which appeared to possess considerable merit.

An Award of Merit was recommended to *Primula Trillii* shown by G. F. WILSON, Esq., Weybridge and Wisley. The plant is evidently closely related to *P. involucrent*. It has similar oblong lanceolate leaves. The flowers were pure white, with a yellow ring at the apex of tube, supported on

Boraginaceæ. It is semi-hardy, and difficult of cultivation, rarely seen in flower in the open. It produces large, fleshy caves, and white flowers with blue centres. (See fig. 100)

Orchid Committee.

Present: Harry J. Veitch, Esq., in the chair; and Messrs. Jas. O'Brien (Hon. Sec.); De B. Crawshaw, H. J. Chapman, R. Brooman-White, W. H. Protheroe, W. H. Young, F. J. Thorne, W. H. White, J. Jacques, Theo. Statter, W. Cobb, E. Hill, J. Douglas, S. Courant, H. Williams and H. M. Pollett.

awarded a First-class Certificate, viz., *Odontoglossum crispum* *heliotropium*, a variety with fine y formed, light rose-colored flowers, the petals bearing many, and the lower lobes of the sepals fewer bright reddish purple spots. The group contained several excellent forms of *O. crispum* and *O. x Andersonianum*; and two plants of the pretty Arddistrach cross-bred *Cattleya x Lawrenceana-Mossie*.

In Mr. ELLIS's group, the specially noteworthy plants were *Odontoglossum crispum* "Cecil Clay," a fine form of the *O. e.* *Trancei* class, with large blotches on the sepals; *O. e.* "Early Elix," another *Euespotei* form; *O. c. roseum*, *O. e.* "Geraldine Mitchell," *O. Pescatorei*, Hazelbourne variety, with petals

spotted with purple, and which had been previously certified. It is *Androsanum*, *Halimolobos* variety, a very handsome flower; *O. citrinum*, *Cattleya citrina*, with fine flowers on a single plant; *Epidendrum ciliare*, *Lycaste aromatica*, &c.

Messrs. F. SANDER & Co., St. Albans, were awarded a Silver Banksian Medal for a good group, in which a conspicuous figure was *Androsanum halimolobos*, a fine pure white variety, growing only 1 foot in height. At the rear of the group some fine spikes of *Oncidium Marshallianum*, *Odontoglossum luteo-purpureum*, and *O. crispum*; well-flowered plants of *Miltouia vexillaria*, *M. leucoglossa*, the pretty little *M. Phalenopsis*, *Mastoclella* \times *Munyania*, the singular salmon-coloured *Cattleya tomentosa*, *Phalenopsis Aphrodite*, a very singular and pretty *Lycaste Skinneri*, with pure white lip, and tips to the petals; *Miltouia Warszewiczii*, *Dendrobium Phalenopsis* *Schroderianum*, and *Vanda Beausson*, were noted.

Messrs. HUGH LOW & Co., Clapton, staged a group, in which were *Odontoglossum* \times *excellentia* *Lewisii*, a very fine form, with bright yellow flowers, spotted with chestnut-brown, the spike carrying fifteen flowers, and secured an Award of Merit. Plants were shown of *Bulbophyllum claptense*, resembling a very dark-coloured *B. Loblii*; *Cattleya Lawrenceana*, with flowers entirely of a lilac hue; *Odontoglossum Andersonianum flavescens*, an unspotted variety; a number of fine *Cattleya Mendochii*, *Odontoglossum crispum*, and other *Odontoglossums*, *Lobelia-Cattleya* *Schilleriana*, *Oncidium papilio*, *O. phymatocolum*, *O. carodes*, *Dendrobium Bensoni*, *D. lituitiforme*, *Cypripedium Curtisii*, \times *grande*, and its darker variety *stratum* (Silver Banksian Medal).

Messrs. B. S. WILLIAMS & SON, Victoria and Paradise Nurseries, Upper Holloway, N., received a Silver Banksian Medal for a very effective group, consisting of fine varieties of *Cattleya Mendochii*, \times *Lawrenceana*, a large number of showy *Odontoglossum*, *Calanthe variegatifolia*, *Dendrobium Devoniense*, *D. crystallinum*, and *D. thyrsiferum*, *Eulophia Elisabetha*, *Lycaste Schilleriana*, a singular and pretty variety of *Miltouia spectabilis*, with some purple marks on the petals, and several radiating dark rose lines on the lip; *Cypripedium* \times *grande*, *C. Boxallii*, *C. hartshornii* *Warneri*, *C. x vermiculatum*, *Oncidium concolor*, *O. Phalenopsis*, the very pretty *Trichocentrum tigrinum*, *Vanda suavis*, *Ad. aurantiaca*, &c.

Major JOCEY, Sunningdale Park, Sunningdale (gr. Mr. Fred J. Thorne), staged a splendid example of the bright orange-coloured *Cattleya*, with flowers entirely of a pendulous raceme of seventy-four flowers (Cultural Commendation), and a fine inflorescence of *Eriopsis trilobulifera* with greenish-gold and purple sepals and petals, and pure white lip spotted with purple.

Mr. the Marquis of CAMBER, Buxton Abbey, Kent (gr. Mr. A. Methuen), received a Cultural Commendation for a fine example of *Dendrobium thyrsiferum* with twenty-seven spikes, averaging over forty flowers each; and which was purchased at Messrs. Protheroe and Morris' Rooms as a single piece some two or three years ago.

W. MORTON, Esq., Lakeland, Rydell, Surrey (gr. Mr. P. Bradley), staged a fine single specimen of *Laelia purpurata* with two spikes, the one bearing seven, and the other five fine flowers.

W. M. WHITE PALMER, Esq., Rutland Lodge, Kent, showed a fine single specimen of *Dendrobium infundibulum*, with a large number of white flowers with yellow blotch on the lip (Cultural Commendation).

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr. Mr. Aldous), showed *Odontoglossum Hallii*, *Rosslyn Hill*, a very handsome form, with broad sepals and petals with very dark marking, and pure white lip blotched with brown.

MALCOLM S. COOPER, Esq., Kingston Hill, showed a group in the centre of which was a finely-flowered *Miltouia vexillaria*, and with it good *Odontoglossum crispum*, *O. Halii*, *Mastoclella* \times *Chelsonii*, and *Sophrantis grandiflora*. (Bronze Banksian Medal)

E. J. STEPHENSON, Esq., Bowdon, Cheshire, showed *Dendrobium noble* *Sanderianum*, with flowers tinted with a peculiar pale cherry-red hue.

Narcissus Committee.

President.—Messrs. C. R. SCARSDICKS, Jas. Walker, A. Kingsmill, W. Barr, J. D. Bennett Post, Miss Willmott, and others. The display of Narcissi was naturally less in quantity than on the 13th; but flowers from the North, and from Holland, where the season seems backward rather than early, were still shown in fair abundance, and excellent in quality.

Messrs. BARR staged an imposing bank of the various sections, the prominent feature being a large gathering of their fine new *Ajax*, *Victoria*, a flower of the form and stout substance which gained an Award of Merit. The large new *Trumpets*, *Shake-pears* and *Fred Moore*, also attracted attention (*Silver Flora Medal*).

Messrs. VEITCH included in their exhibit, which was very tastefully set up with foliage and Ferns, a considerable number of their well-known forms, of which, a bell-shaped flower, with brilliant red, or heightened crown. The committee desired to see again when more fully expanded. The white *Trumpet*—*Madame de Graaff*—was exceptionally good in this stand (*Silver Flora Medal*).

Mr. J. W. WILSON, Dreston Street, South Cave, Yorks, obtained a *Silver Flora Medal* for a considerable and varied collection, which had travelled well.

The Rev. G. H. ENGLEHART showed a small selection of new hybrids, noticeably a strain of *poeticus*, intermediate

between the early-blooming *ornatus* and the late *verrucosa* and *virida*, yielding circular, flat-petalled flowers, intermarrying in form and season. A late incomparably, with sulphur-white divisions, and very large, open yellow, took the prize for the best seedling of the meeting, and a very graceful hybrid between *poeticus* and *trianthus*, with several delicately tinted flowers on each stem, was awarded a First-class Certificate.

Mr. W. WILKS, Shirley Vicarage, Croydon, showed an extraordinarily large-flowered and robust form of *N. biflorus* (Award of Merit).

Fruit and Vegetable Committee.

Present: Philip Crowley, Esq. (chairman); and Messrs. Jos. Cheal, Jas. H. Veitch, A. F. Barron, A. H. Pearson, J. Wright, Alex. Dean, W. Farr, J. W. Bates, Geo. Woodward, John A. Laing, Geo. Wythes, F. Q. Lane, Jas. Smith, J. Willard, and Robt. Pye.

Mr. Wytles, jr. to EARL PERCY, Syon House, showed a select lot of vegetables in season. We remarked in varieties of Potatoes—*Sutton's A1*, *Early May*, like *Monia's Pride* in shape; *Sharpe's Victor*, *Flagship* *Blue Improved*, and *Myatt's Ashleaf*. Of Broccoli, there were *Sutton's Late Queen*—surely out of season(?), and *Veitch's Model*; *Cabbage Sutton's Early Favourite*, and apparently early hearting varieties; some very robust heads of *Seakale*; and ripe and green Tomatoes, as grown on the same bench. *Fig St. John*, a variety of a vivid green colour in the ripe state, is very fine. Royal Sovereign Strawberries, taken from plants averaging eight to ten fruits on each; and *Keen's Seedling*, of good size, from plants carrying the same number. Some new and old black and white Grapes came also from Syon. An Award of a Silver Banksian Medal.

Messrs. HENRY & SON, Houndshead, contributed some heads of a fine large Broccoli under the name of *Hurst's Early April*. It is somewhat cone-shaped, the curd creamy-white and firm.

Mr. RUSSELL, Parahomb, showed a new variety of Strawberry, named *Early Giant*, a large corrugated fruit, of poor flavour, said to have been raised from Sir J. Paxton and George Rivers. It is interesting that the flavour is not better, coming from such good sources.

Mr. O. THOMAS, gardener to the QUEEN, Eyremore, showed capital yellow-fruited Tomato *Royal Windsor*, a fruit of large size and fine flavour. It is oblate, and slightly corrugated. The information was accorded that it is the result of a cross between *Empress* *Prince* and *Eyremore* *Selected*. Judging from a piece of stem shown it is a prolific variety (Award of Merit). Fruits of the latter were also shown—smooth, crimson-coloured fruits; also, some of a new Strawberry, called *Sir Trevor*, out of *La Grosse Sucrée* and *Royal Sovereign*. The fruits throughout were of a Cook's shape, large, and of good flavour.

Dwarf French Beans *N. Plus Ultra* and *Early Favourite* were shown by Messrs. J. VEITCH; the former being likewise shown by Messrs. WATKINS & SIMONS; Dwarf French Bean *Empereur William* by Mr. ERNEST BENARY, Erfurt—a broad, flat pod, with prominent seeds; *Molokai Improved* French Bean, by Mr. W. WATMAN, and *Gulden Was Bein*, by Messrs. BAKER & SONS; *Oborn's Foreing*, by WATKINS & SIMONS; and by DAMMAN & Co.; received an Award of Merit.

In the competition for the highest flavour in Apples, which has now greatly fallen off in regard to the number of exhibits, the 1st prize fell to Mr. C. HERBIN, Dropmore, with *Stomax Pippin*; 2nd to Mr. T. LALOX, Bury St. Edmunds, with *Brandy Pippin*. A few other varieties of Apples were shown, including *Baxley's Pearmain*, *Claygate Pearmain*, and *Scarlet Nonpareil*.

Messrs. HILLIER, Winchester, showed handsome fruits of *Hilli's Easter Orange Apple*, said to have a tender flesh and pleasant flavour (an Award of Merit).

The Lecture.

In the afternoon Mr. ALEX. DEAN read a paper upon "Winter and Spring Bedding." The lecture was prepared by a few general remarks upon the whole subject of "bedding out," or the planting of beds with diverse plants to create a bright and showy appearance where such planting had been practically contrived with a view to good results, but admitted that extremists had sought "vulgar effects," and had made "garish combinations." Later, when speaking of spring gardening more particularly, a stronger view was taken, and the massing of Tulips and *Hyacinths* in squares, but beds severely depressed. Those who profess to admire such displays of bulbs as are to be seen annually in the London parks and elsewhere, were placed in the same category as persons who prefer the displayed posters upon the hoarding in the streets to the exhibits in the National Gallery.

Mr. DEAN referred in appreciative terms to the manner in which the beds at Chiseldon and Heckfield were furnished by *Fleming and Wildsmith* respectively, and added, that since their days, particularly *Fleming's*, there had been placed within reach of the gardener a large number of coniferous and other plants, particularly suitable for the purpose of furnishing beds during winter and spring. In referring to a paper upon the subject, read before the Royal Horticultural Society a few years since, by the Rev. W. Wilks, Mr. DEAN criticised the view then expressed, that the plants should be kept in pots, to be merely plunged in the beds during the winter months, and that, during the flowering shrubs, if moved twice during the year, would make comparatively little growth, but that they would develop a mass of fibrous roots, and by means of such escape injury.

A very long list of plants suitable for planting in beds was attached to the paper, but not read, Mr. DEAN remarking that, apart from *Conifers*, there were *Skimmias*, *Aucubas*, *Persea*, *Rhododendrons*, *Camellias*, *Freesias*, *Hyacinths*, *Prunellas*, *variegated Conifers*, *Ribbon-grass* (*Phalaxis arundinacea variegata*), *variegated Crosses*, *etc.* *Tulips*, *Hyacinths*, *Squills*, and other bulbs, though not desirable when massed, were nevertheless invaluable to plant with discretion among the other plants.

The Chairman, the Rev. G. H. Englehart, was not prepared to endorse Mr. DEAN's mode of massing spring-flowering plants and bulbs, and thought that if we were to give up "massing," our colours altogether we should be ignoring a lesson frequently taught us by Nature, instancing the sheet of colour produced by the wild *Hyacinths* in Hampshire. The Rev. Mr. Wilks said he remained perfectly unconvinced in the matter of transplanting his shrubs and plants twice each year in preference to keeping them in pots. He would defy Mr. DEAN by the system he recommended to successfully treat "tree" Ivies, and if he discarded those he would discard one of the most useful and suitable plants for furnishing beds in winter. The "tree" Ivy is the form that Ivy assumes after it has reached the top of a wall, and therefore ceased to climb. If these shoots are cut off and struck, they maintain the "tree" spike already assumed. All Ivies are impatient of transplantation or interference with roots and "tree" Ivies especially so.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

APRIL 23.—At an adjourned meeting held in the Memorial Hall, Albert Square, Manchester, on the above date, George Shorland Ball, Esq., of Ashford, in the chair, the following proposals were made and seconded by various gentlemen present.—That the society be called the Manchester and North of England Orchid Society, with an entrance fee of one guinea, and an annual subscription of one guinea; that the Right Hon. J. Chamberlain, M.P., be invited to become the first president; that A. Eschworth, Esq., Harefield Hall, Wilmslow, be appointed chairman of the Society and of the Orchid Committee, and W. Thomson, Esq., Walton Grange, Stono, vice-chairman; G. Shorland Ball, Esq., Ashford, Wilmslow, honorary treasurer; and W. A. Gent, Esq., 11, Faulkner Street, Manchester, honorary secretary. The following twelve gentlemen were elected members of the Committee, viz., Messrs. J. Anderson, W. Bolton, H. Greenwood, Capt. G. W. Law Schofield, Thos. Statter, E. J. Sidebotham, W. Stevens, A. Warburton and V. Weathers.

The Honorary Secretary intimated that twenty-nine gentlemen had declared their willingness to become members, and it is expected when the thing becomes public, that that number will be at least doubled. The object of the promoters is to get up a sufficient fund to provide, first and foremost, the necessary expenses, then to set apart so much for providing medals and prizes that may be awarded from time to time. It is also contemplated that at the great shows of the Royal Botanic, prizes shall be given from this Orchid Society to such exhibitors, more individual than collective, as are of sterling merit. It is not intended that the meetings held in Manchester should clash with the meetings of the Royal Horticultural Society, so that on each alternate Tuesday the meetings will be held. In this way it is just possible we may see some of the choicest Orchids at both London and Manchester. The new venture will, in fact, be an auxiliary, not subsidiary to the central body in London. The aim is to get only the choicest of Orchids, come from where they may, rather than indiscriminate lots for sale to the public. For all matters connected with the Royal Botanic Street, the Hon. Sec., and Mr. Geo. Shorland Ball, 1, Princess Street, the Hon. Treasurer, will supply the necessary information.

The following plants in pots, all beautifully flowered, were sent for the inspection of gentlemen present:—A new and beautiful hybrid *Odontoglossum*, elsewhere described as a natural cross between *O. crispum* and *O. citrinum*; a splendid plant of *O. Wilckeanum* with two spikes 20 inches long, and the flowers very large, and beautifully developed; an equally noteworthy *O. luteo-purpureum*; a magnificent *Halli xanthoglossum*, and a *Cattleya Lawrenceana* with about twenty-four flowers of such brilliancy as one does not often see with a large bill and a broad base. The segments of the petals, the whole lot in perfect health. These came from W. THOMPSON, Esq., of Walton Grange, Stono.

A very choice *Odontoglossum crispum*, with immense flowers, came from JOHN LEWANN, Esq., West Bank House, Heston Mersey; which each member would measure about 4 inches by 4 inches, of white ground colour, with great prominent deep chestnut blotches, looking as if the better beauty of the petals were broken down. The segments were a bit open, but for adorning a lady's person, the spike with ten flowers in it would be picked by a lady expert, before such close-segmented sorts as those that you have from time to time illustrated in the pages of the *Gardeners' Chronicle*: the committee, although partly formed, did not indicate upon their list all the things that they thought for future meetings will be recognised. In case of any difference of opinion, if a vote requires to be taken, it will be taken by ballot. J. A.

FORESTRY.

TYPES OF BRITISH WOODLAND.

(Continued from p. 276.)

MIXED PLANTATIONS.—The formation of mixed plantations on the British method is probably due to two principal ideas. One of these is that variety of species leads to a varied effect in the appearance of the plantation, and the other that amongst a number of different species one or more is sure to thrive, and lead to a promising plantation. In the majority of cases, however, neither of these ideas is justified by results. A certain amount of variety undoubtedly exists in mixed woods, but not in proportion to the number of species used, nor more than may be found in many a pure or nearly pure wood, composed of common forest trees. On the contrary, indiscriminate mixtures planted with mathematical precision have as little effect in making a varied landscape as the particular pattern of a wall-paper has in varying the general artistic effect in the decoration of a room. Harmony rather than variety should be the aim of the landscape planter, and although other than aesthetic considerations may have to be studied, there is no reason why sound principles should not be introduced in forming plantations of this kind, which combine economy and taste without a wide departure from existing customs. As a sylvicultural success, again, the ordinary mixed plantation forms rather the exception than the rule. Experience proves that tall, clean timber is most easily produced when the trees in a wood all belong to the same species, and are of about the same age at the start. On economical grounds, however, it is sometimes desirable to introduce other species, which have a subordinate office to fulfil, such as preserving the fertility of the soil or increasing the bulk of timber on the ground. The ordinary mixture neither furnishes useful timber in proportion to the planted area, nor is the ground utilised in an economical manner, although exceptions to this statement may be met with now and again. Trees which vary greatly in their rate of growth, their longevity, or their shade-bearing capabilities, sooner or later lose touch with their neighbours, and are killed out altogether, or assume an unrestricted height of growth which seriously decreases their value as timber-trees. No doubt careful thinning may do much to improve matters and remedy these defects, but the time and attention necessary for this are not always forthcoming, and the plantation, under the most favourable conditions of growth, usually becomes one of those arbor-sylvicultural combinations so dear to the heart of a certain class of forester. But while it may be easy enough to find fault with the existing state of things, it is more difficult to find an effectual remedy. Planters have to consider their reputations, and all are not in the doubtfully-happy position of a gardener to a certain noble duke, who, when instructed to thin a plantation by his employer, replied that his reputation might suffer by so doing. "Do as I wish you," said the Duke, "and I will take care of your reputation," which he did by erecting a notice-board at the edge of the plantation, stating that the latter had been thinned by himself, contrary to the advice and opinion of his gardener. The British forester who planted his woods without the orthodox mixing formula would be risking the loss of a good name if the species selected did not prove altogether a success on the soil and situation. With a comprehensive catalogue before him, it seems almost like tempting Providence to stake all upon one or two kinds of trees, although our predecessors of two or three generations back appear to have adopted this plan with tolerable success—but perhaps they knew no better. At any rate, they had no opportunity of making a selection from several hundred exotic trees, all of which, if we are to believe their introducers, are invaluable as timber producers. That they do not always fulfil the high expectations aroused in the minds of planters, however, is due to no fault of the trees themselves, nor to those who, meeting them in their native habitat, see them as they ought to be,

and not as they become when planted in unfavourable soils and situations in this country. If, by a happy combination of circumstances, fresh introductions happen to be placed in sites which suit them, their success is frequently regarded as indicating their suitability for extensive planting in this country. If, on the other hand, their growth is not satisfactory, they are prematurely condemned before a fair trial has been granted them. Hence arise those contradictory statements regarding the value of a particular species for our climate, and the uncertainty existing in the minds of planters which results in the planting of mixtures in which variety is more conspicuous than congruity, and which deprives British woods of a good deal of their British character. A. C. Forbes.

(To be continued.)

NURSERY NOTE.

DAFFODILS AT SPALDING.

I HAD recently an opportunity of inspecting the Daffodil Farm of Mr. J. W. White, of Spalding. He has 20 acres of Lent Lilies, divided into two portions, but practically contiguous. The dark soft loam, no doubt covered with water in times past, greatly resembles the soil of the bulb farms of Holland, but is rather heavier, and it may be said to suit Narcissus and Tulips admirably. There is a depth of 15 inches or so, resting upon a subsoil of silt, which may be described as a fluviatile sediment of mud hardened into mould, and when taken in the hand it readily crumbles to powder, being of a soft floury nature. In preparing the ground for planting, a kind of bastard treecching is done. The top spit is thrown over, and then the fork is plunged into the silt, simply loosening it, but not turning it over in any way, and so making it porous. Mr. White has had the land under cultivation for the space of twenty years; and as he brings to the work keen intelligence and foresight, it is not surprising that his success has been commensurate with his enterprise. Mr. White grows Daffodils to supply the trade, and the quality of his bulbs being high, they are in great demand. When one sees bed after bed, and plantation after plantation, of one variety, as at Spalding—300,000 of this, a quarter of a million of that, some idea of the popularity of the Daffodil is realised.

The varieties are in some cases in beds, seven bulbs in a row, following the practice of the old Tulip-growers; and these beds seem innumerable. Then there are huge plantations of varying lengths, some 10 yards in width, and some 12. Imagine a bed of *N. bicolor* Empress, or one of *N. poeticus ornatus*, 160 yards in length, by 12 in width; and, seeing that the strong bulbs—these which will be offered for sale in late summer—produce four and five, up to six and seven blossoms each, the impressiveness of the mass can be imagined. I was struck with the order and cleanliness everywhere, scarcely a weed visible with the Daffodils the rich plant-food in the soil.

Mr. White confines his collection to a few leading varieties, which are among the most popular, and in the greatest demand. Of the Ajax or Trumpet Daffodils, Empress, Empress, Grandis, and Hosierville lead the way; and the double Van Sion, which here is superbly double and symmetrical, thousands of blooms attract the eye and compel admiration. Of the medio-cornati section, Sir Watkin, of the double Incomparabilis type, *Albus plenus aurantius* (Orange Phebus), and of the Barri type, Consensus, and one or two others. I leave out of mention Glory of Leyden, Madame de Graf, and a few newer forms which find a place on the farm in necessarily small quantities at present. Mr. White is swift to see what are likely to be popular varieties; the commoner forms, whose commercial value rapidly declines, he leaves to others.

As a matter of course, beds are sown containing bulbs of differing development. There are those of young offsets planted last autumn, there are those of a year older, and those a year older still; it requires

from two to three years to produce a good fat round bulb of first quality for sale. At this period of the year thousands of cut-blossoms are sent to market; this being a most active industry, giving employment to many pairs of hands while it lasts. At the end of the summer comes the harvesting, the drying, selecting of the bulbs, and the execution of orders, the bulbs being despatched to their destinations in hampers, so as to admit of air circulating among them while in bulk.

It may be added that Mr. White does a large business with double Snowdrops, as they do remarkably well in the district, though apparently at times somewhat fastidious as to soil and position. He purchases from the small growers, and in this way is enabled to execute orders for large quantities. The culture of Snowdrops is thus also a notable industry in the locality. In one corner of the farm I saw a huge patch of Winter Aconites growing with amazing luxuriance, producing plump tuberosous roots.

In specially constructed houses of considerable dimensions, Mr. White grows Tomatoes on a large scale, the plants already approaching blooming. The houses are employed in winter and spring for forcing Narcissus into bloom. The roots are placed in boxes, and yield a supply of bloom when prices are best. R. D.

THE WEATHER.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

The districts indicated by number in the first column are the following:—

- 0, Scotland N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. Principal Grazing Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, S.; 10, Ireland, S.; *Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending April 24, is furnished from the Meteorological Office:—

"The Weather continued unsettled, with rain at times, during the earlier part of the period, but later on it became dry and fine—first in the north and west, and subsequently in the other parts of the kingdom.

"The temperature was rather below the mean in all districts excepting the 'Channel Islands.' The highest of the maxima, which were recorded during the earlier part of the week, ranged from 63° in 'Ireland, N.' (at Londonderry), and 61° in the 'Channel Islands,' to 71° in 'Scotland, W.,' and over 70° in east and west England, and to 54° in 'England, N.W.' The lowest of the minima were registered on the 23rd, and ranged from 29° in 'Scotland, E.,' and 27° in 'Scotland, N. and W.,' to 30° in the 'Midland counties,' 37° in 'England, S.,' and 39° in the 'Channel Islands.'

"The rainfall was rather more than the mean in 'England, N.W.' and 'Ireland, N.' and just equal to it in the 'Midland counties'..."

"The bright sunshine exceeded the mean in all districts except 'England, S.W.' and the 'Channel Islands'..."

MARKETS.

COVEY GARDEN, APRIL 29.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday...

Table with columns: s. d. s. d. and items like Anemones, Arums, Azaleas, Bouvardias, Carnations, Dahlias, etc.

CUT FLOWERS.—AVERAGE WHOLESALE PRICES.

Table with columns: s. d. s. d. and items like Geraniums, Heliotropes, Impatiens, Pinks, etc.

FRUIT.—AVERAGE WHOLESALE PRICES.

ENQUIRY.

Would some reader of the Gardeners' Chronicle kindly inform M. F. if dressings of Kainit would destroy the kind of eel-worm (Tylenchus devastatrix), which attacks several species of grasses...

NOTICES TO CORRESPONDENTS.

ACACIA DELEBRATA: B. S. Wood. The leaves might fall from the plants from a variety of causes. It may have got very dry at the root on the journey from Cannes...

AREMONE: T. Bibby. The foliage shows no fungus disease, nor do the roots. It is possible that in a more advanced stage, there might be evidence of the presence of a "rot-mould" similar to that of the Potato-disease.

CHERRIES DESTROYED WHILE QUITE SMALL: C. We found no insects in or on the fruits, but doubtless the injury was due to an attack of the small caterpillars of the winter-moth...

FUNGUS ON A LARCH POST: A. C. F. It is a large Myxomyetete, in an early and imperfect stage, called Reticularia lycoperdon. It becomes when ripe a powdery mass of amber-brown spores.

INSECTS ON PEAR: F. W. Thomas. The caterpillars sent are those of the winter-moth. Spray the trees with Emerald (Paris) Green at the rate of 1/2 lb. to 5/8 gallons of water...

Mark's Fly). See Gardeners' Chronicle, 1844, Nov. 16, for fig. &c. The best remedy against the larva is haul-picking, which is not attended with any difficulty...

MOSSY LAWN: Moss. With an iron rake scratch off all the moss you can, then dress the surface with loam three-quarters, and one-quarter sifted wood-ashes...

MUSHROOM-GILLS ATTACKED BY A MOULD: A. E. It is not uncommon for Mushroom-gills to be attacked by the mould on the gills. It has nothing to do with the spawn. This is the first stage of a kind of Hypomyces...

NAME OF FRUIT: W. H. G., Crocton, Apple Datch Mignoone.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—C. L. 1, Dendrobium chrysotoxum; 2, Obolobosium; 3, Orlanthea; 4, Obolobosium; 5, Obolobosium; 6, Obolobosium; 7, Obolobosium; 8, Obolobosium; 9, Obolobosium; 10, Obolobosium...

PEACHES: Arcatum. Milkew; remove the infected fruits, and burn them. Use sulphur on the hot-water pipes. See our issue for April 24, p. 250.

SUTTON'S FORCING FRENCH BEAN: A. C. The variety was not sent for trial.

VINES: Thistle Brothers. If the points of the shoots turn brown in colour, and become lathery, and the nuddy subsequently attacks the leaves, the Vines are suffering from the so called "browning," an obscure disease caused by a slime-fungus.

THE

Gardeners' Chronicle.

SATURDAY, MAY 8, 1897.

THE FORESTS OF WESTERN AUSTRALIA.

PROBABLY more persons in this country have heard of the Coolgardie railway and gold-field, its lack of water, and its barren surroundings, than of the vast forest belt and saw-mills of the south-western part of Western Australia. But even to those who knew of the existence of colossal Gum-trees, Mr. J. E. Brown's official report as to the extent and value of the forests of this colony,* is in the nature of a revelation. Mr. Brown has been successively Conservator of Forests for South Australia, and Director-General of Forests in New South Wales, so that he brings some experience to bear on his task; and certainly the report before us is a model of conciseness, whilst the illustrations, though somewhat cloudy, are extremely interesting and instructive.

Mr. Brown estimates that the Australian colonies combined possess an area of 47,000,000 acres upon which useful marketable timber is actually growing. He further puts the number of different species of Australian timber trees at 600, but this would include everything in the shape of a tree. There is, of course, a vast number of different kinds of trees that produce timber, or perhaps one should say wood, that is useful for home industries and local purposes, though not for export; indeed, Mr. Brown's list of the principal forest-trees of Western Australia is limited to thirty-five species, half of which belong to the genus *Eucalyptus*, seven belong to the genus *Banksia*, three to *Casuarina*, three to *Acacia*; and the others are—*Agonis flexuosa*, *Frenela verrucosa*, *Melaleuca Leucadendron*, and *Santalum cyngrorum*. With the exception of the *Santalum* (Sandal wood), which is exported to the value of upwards of £30,000 in some years, it is only a few of the species of *Eucalyptus* that are of any great commercial value. Foremost among these is the Jarrah, *Eucalyptus marginata*, a species restricted to the south-west, between King George's Sound and Cape Leeuwin, and northward to the Moore river. Although the most valuable of the timber-trees, its appearance is neither noble nor impressive. Our author says: "Taken as a whole, there is nothing particularly picturesque about the appearance of a Jarrah tree, or of a forest of them. Indeed, the general effect is dull, sombre, and uninteresting to the eye. Except in special spots and localities, the trees are rugged, and decidedly inclined to be straggling and branchy."

The Jarrah is surpassed in size by several other species of *Eucalyptus*; yet trees from

* Rep. on the Forests of Western Australia, their Description, Utilization, and Proposed Future Management, with plan and illustrations. (Perth, W. Australia, 1896.)

† I should mention that only a few of the species of *Eucalyptus* are called Gum-trees in the colonies.

90 to 120 feet high, with trunks from 3 to 5 feet in diameter, and 50 to 60 feet to the first branch, abound in some districts. Individual trees occur of much larger dimensions, up to 150 feet high, with a girth of 22 feet at 5 feet from the ground, and 80 feet up to the first branch. There are records of even larger trees.

The Karri, *E. diversicolor*, is the next in importance. This, Mr. Brown describes as the giant tree of Western Australia, if not of the whole Australian continent; an assertion, he adds, he makes without much fear of contradiction, though he gives no measurements in support of it. On the other hand, the late Sir F. von Mueller has put on record that he had observed many Karri trees which approached 400 feet in height, and he mentions one that was 300 feet up to the first branch; but he gives even larger dimensions for *E. amygdalina* of the eastern colonies.

The Karri is now extensively cultivated in the Mediterranean region, where it is, or was, generally known under the name of *E. collosa*. Mr. Brown says there is no doubt that the Karri is the finest and most graceful tree in the Australian forests, the mature trees being grand in the extreme. The tall, clean trunks are of a polished white. Painting No. 782 in the "North" Gallery at Kew will give some idea of the grandeur of this tree. Like many other species of *Eucalyptus*, it grows very rapidly; yet it has a very hard wood. Mr. Brown describes one exceptionally fine tree as containing 6000 cubic feet, or 40 tons of timber in the bole, from the ground up to the first branch. The range of this tree is much more restricted than that of the Jarrah, being limited to the country between King George's Sound to the east, and Cape Hamelin to the west, between 115° and 118° of longitude, and 34° to 35° of latitude.

The Toorati, *Eucalyptus gomphocephala*, is another species of commercial value, and is described as a handsome tree, having bright green leaves, like the Karri. Though of smaller dimensions, its timber is classified as the strongest, heaviest, and toughest in the colony. Among other ornamental species, *E. calophylla* and *E. ficifolia* deserve mention; the former for its beautiful foliage, and the latter for its showy crimson flowers.

Some of the universally dispersed *Acacias* are both useful and ornamental. Raspberry Jam is the vernacular name of *A. acuminata*, owing to the scent of the wood, which is said to be remarkably similar to that of Raspberries.

Mr. Brown estimates that the Jarrah, associated with the Blackbutt, *E. patens*, and the Red Gum, *E. calophylla*, covers an area of 8,000,000 acres, and the total of the principal forest area of Western Australia at 20,400,000 acres. He further estimates the total matured timber at 62,300,000 loads, though he considers much more exists. This matured timber, he urges, should be removed, to make way for succeeding crops. The present yearly output of the colony, on the same authority, is about 130,000 loads, from which he calculates that it would take something like 200 years to cut out the timber that is now ready, and thus a large portion would be lost through decay, if there were no increase in the output. If Mr. Brown had said "something like 100 years," he would have been nearer right, assuming his other figures to be correct; but there is a vein of wariness and enthusiasm pervading this report that betokens a little over-estimation. For instance, he has come to the conclusion that a "forest of marketable Karri can be produced in the short

term of from thirty to forty years." This is based upon counting the concentric rings of a tree felled under his supervision; a tree which he characterises as a sapling in comparison with the surrounding members of the forest. It was 153 feet high, about 2 feet in diameter, contained 175 cubic feet of timber, and showed thirty-five concentric rings.

Mr. Brown has enjoyed such opportunities for gaining knowledge in Australian forestry, that we are bound to accept his statements as substantially correct, marvellous as some of them may seem. Even supposing that his ideas are not fully realised, there should be a great future for Australia in her forests, provided they are properly managed. But with regard to rapid growth of Gum-trees, his data are substantiated by other observers, both in Australia and in other countries where Gum-trees have been introduced. Thus it is recorded that *E. amygdalina* grew to a height of 60 feet in nine years in the vicinity of Lago Maggiore; and a specimen of *E. Globulus*, in the same place, fully 120 feet high, was supposed to be only twenty-eight years old.

If we turn to the illustrations, thirty in number, in Mr. Brown's report, we find more convincing evidence, should more convincing evidence be required. There are views in the forests; there are views of individual big trees, both standing and felled; and views of the railways and trains of logs. In short, anyone interested in trees or timber may learn much from Mr. Brown's report. *W. Bolting Hensley.*

ORCHID NOTES AND GLEANINGS.

A CURIOUS ODONTOGLOSSUM.

A VERY singular flower of *Odontoglossum crispum* is sent by Mr. James McLean, Cooksbridge, Leves, Sussex, a clever grower of *Deudoriums* and *Odontoglossum* for market purposes. The upper sepal and the petals are normal, and beyond some laceration of the edges, show no change; the column also is perfect, but there are two labellums, each of them perfect. The lower sepals are joined together for half their length, and exhibit the mid-ribs of three instead of two, each of which carries its blade free for the remaining outer half of its length, the central one being arrow-shaped. The whole is flatly displayed, and the lower sepals assume the form of a trident.

VANDA CRISTATA.

This is a very remarkable species, and through the lesser alpine form, *V. alpina*, seems to connect *Luisia* and *Vanda*; and Lindley originally placed *V. alpina* in that genus. It is rather widely distributed in the Himalayas, and doubtless locally has much to do with its varying from small and merely curious forms to those which are striking and even showy. A very handsome variety is flowering in the Hon. Walter Rothschild's collection at Tring Park. The flowers are 2 inches across, the sepals and petals cream-coloured, tinged with green; the large fleshy labellum, which bears at the apex the usual diverging horn-like process, but much enlarged, is concolorate, and in colour deep blood-red, with the raised portions pure white. The flowers vary in the proportion of white and red in the lip, but all are very striking and attractive.

ZYGOPETALUM BURTH VAR. WALLISII.

This remarkable variety is so much larger and finer than the type in every respect, that Professor Reichenbach at first took it for a distinct species, and described it under the old sub-generic name as *Batemania Wallisii*. A superb form of it is now in flower in the Right Hon. Lord Rothschild's gardens, Tring Park. The large wax-like flowers are just 5 inches across; the broad sepals are white at the base, changing to pale yellow, and their warty

glossy surfaces are tinged with chestnut-brown, a yellow band enclosing the lower area. The petals are similarly coloured, but have at the base a patch of purple lines and blotches. The base of the lip is white, with a crest of purple spines, the apex being dull purple. Column white, with green and purple wings. It is a very rare plant, and at Trieg it thrives well.

ORCHIDS AT ASEFOLD, WILMSLOW, CHESHIRE.

The collection of O. Shorland Ball, Esq., has taken a leading position among the many collections of Orchids around Manchester, and it is likely to hold its own, for the Orchid-houses have been built of the best possible kind, fitted with modern appliances. The gardener, Mr. Alex. Hay, is a diligent, practical man, who evidently loves his calling and his charge. In the houses, whether cool or warm, a healthy atmosphere is noticeable, which a glance at the arrangements of the houses sufficiently accounts for.

which has been called *Cattleya labiata* Balliana, for it is difficult to decide definitely to which section of *C. labiata* it belongs. It is, however, a very pretty and distinct form with pure white sepals and petals, and light orange disc to the lip, the anterior portion of which has a slight tinge of pink. With the *Cattleyas* were arranged good forms of *Lycaste Skinneri*, *Cymbidium churruum*: fine specimens of *Dendrobium densiflorum*, *D. thyrsoiflorum*, *D. Phalaenopsis*, *D. Findlayanum*, and other *Dendrobiums*; *Miltonia vexillaria*, *M. Phalaenopsis*, &c.

In the large *Dendrobium*-house were in bloom the latest of the *Dendrobium nobile*, of which there is a very fine collection, two of the best and most distinct being the true *D. nobile nobiliss*, and the blush-white *D. n. Ballianum*. Also in flower were *D. × Schroederianum*, *D. × Aspasia*, *D. luteolum*, *D. Findlayanum*, *D. Devonianum*, and many fine specimens of *D. Phalaenopsis Schroederianum*. Near the glass end of the house and in a position where

Philippine Islands. After having at first collected some plants which bore no flowers, but which revealed a novelty by their habit, he was suddenly abandoned by the prisoners who had been given him as an escort. "I was then obliged," writes M. Roebelen, "to descend to the plain, and after a somewhat lengthy palaver with the chief of the tribe, he consented to supply me with any number of carriers, provided I handed over everything in my possession, and particularly my umbrellas, which he wanted for his wife.

"I set out the same day about 10 A.M., and at 6 P.M. reached the dwelling of a transported Spaniard, who cultivated a few Cocoa-trees around his miserable hut. I remained with him some days, in order to pick my plants, and it was he who accompanied me the first day in his little boat, having no servants at his disposal. On landing in the evening, I saw at the top of a tree some flowers, which appeared to me to be those of a *Vanda*, and some minutes afterwards,

FIG. 101.—CATALPA SYRINGIFOLIA AT HEYWOOD, WESTBURY, WILTSHIRE.

In the first place, the natural earth forms the floor, and over this are neat and durable wood-work trellises extending the whole width of the paths. This arrangement is the best possible for Orchid-house flooring, and if in houses where the baneful concrete-floors still exists were removed and the natural earth with trellis over substituted, immediate good results would be secured. Secondly, the houses are not painted, but the wood-work is simply coated with some preservative; and thirdly, the houses are fitted with the lath roller-blinds running well above the glass, and thus admitting a maximum of clear light without fear of scorching by the sun's rays. With these and many other sanitary arrangements, Mr. Ball has secured a model block of Orchid-houses, with the result that his plants are in splendid condition in every department.

In one house used for arranging together some of the larger species when in flower, we found a very fine display made up of well flowered examples of *Cattleya Schroderae*. *C. Schroderae alba*, and other *Cattleyas*, among which was a very handsome variety

they could feel the influence of the outer air, some fine specimens of *D. Falconeri* were flourishing. On several occasions we have seen this plant, which many growers utterly fail satisfactorily doing well in a similar position.

The *Cattleya*-house contained a good collection of *Cattleyas*, together with *Epidendrum Wallisii* and other species; the *Cypripedium* houses a rare and valuable selection, including *C. callosum* Sanderae, *C. Lawiæocanum* Hyesnum, and *C. insigne* Sanderae. In bloom were the handsome *C. × triumphans*, and other hybrids and species.

The cool-houses had a good show of *Odontoglossums*, *Maslovallias*, &c., all in the best possible condition. *J. O'B.*

VANDA SANDERIANA.

"M. Roebelen, to whom the honour of discovering this brilliant species (*Vanda Sanderiana*) belongs, has related, in the *Journal des Orchidés* for 1894, the conditions under which he procured it, towards the end of 1881, in the neighbourhood of Davao, in the

spite of the very palpable protestations of the ants which disputed my right to the plant, I held the beautiful *Vanda* in my hand. All my miseries and all my fatigues were at that moment forgotten. It is necessary to have travelled in order to realise the joy experienced at the discovery of a new plant, and that such an one as *Vanda Sanderiana*. The little plant had three stems and forty-two flowers." *Lindley, L. DLXVII.*

CATALPA SYRINGIFOLIA.

We are almost as familiar with the *Catalpa* as with the Horse-Chestnut, but, in both cases, familiarity does but enhance our estimation. The *Egnoquias*, to which group this tree belongs, are mostly climbers, but the members of this particular genus are trees—natives of the United States and Japan. The species first introduced was the one, an example of which is figured on this page. It made its appearance originally in 1726, and its noble foliage and showy flower-panicles soon brought it into favour;

moreover, it forms an excellent town tree, and may, or might recently have been, met with in the enclosures of the Temple and Lincoln's Inn. The specimen figured is in the garden of Lord Justice Lopes at Heywood, Westbury, Wilts.

A specimen 40 feet in height, and 170 feet in circumference of the head, is to be seen at Thorne Hill Park, Bitterne; and another large specimen was figured in our columns in January, 1876.

NOTE ON AMERICAN ERYTHRONIUMS.

Mr. R. WALLACE, of Colchester, has lately brought me fine living plants of an Erythronium I was very pleased to see. It has flowers as large and peduncles as tall as in *E. giganteum* (*Bot. Mag.*, t. 5714), but the flowers are bright mauve-purple instead of creamy-white. The leaves are conspicuously mottled, and the style distinctly tricuspidate, with three falcate stigmas. It agrees with *E. revolutum* of Smith, described in 1819 in the thirteenth volume of the *Cyclopaedia or Universal Dictionary of Arts, Sciences, and Literature*, edited by Dr. Abraham Rees, F.R.S., F.L.S. This plant was collected by Menzies in Vancouver's Island, and was the first Erythronium described from Western America. Hooker, in his *Flora Borali-Americae*, called it *E. grandiflorum*, Pursh, var. *Smithii*; but in point of fact *revolutum* is an earlier name than either *grandiflorum* or *giganteum*. There is in the Kew herbarium one of the original specimens gathered by Menzies, and with this Mr. Wallace's plant entirely agrees. When Smith described *E. revolutum* in 1819, only three species of the genus were known, *Doon-canis*, *americanum* (which, as it was not the only American species, he proposed to rename *flavum*), and *revolutum*. When I monographed the genus in 1873, in the fourteenth volume of the *Journal of the Linnean Society*, five species only were known. Since that date the American species have been studied very carefully by the botanists who lived amongst them, and one of the late papers written by the late lamented Dr. Sereno Watson was a new monograph of the genus, published in 1891, in the eighteenth series of his contributions to North American botany, in the twenty-sixth volume of the *Proceedings of the American Academy of Arts and Sciences*. He does not seem to have been acquainted with the genuine *E. revolutum*, but describes an *E. revolutum* var. *Bolanderi*, to which the plant now cultivated by Mr. Wallace and others, under the name of *E. Smithii*, seems to belong. The following is a classified list of the American species as they now stand:—

Group I.—Eastern species. Scapes short, always one-flowered. Inner petals not crested.

* Offshoots produced from the base of the stem.
1. *E. americanum*, Ker., *Bot. Mag.*, t. 1113. Flowers yellow, often tinged with purple, and finely dotted.

2. *E. albidum*, Nuttall.—Flowers white, with more or less of a bluish or purplish tinge.

3. *E. mesochlanum*, Kerr.—Very near the last.
** Offshoots produced from the sheathing portion of the base of the scape.

4. *E. propallans*, A. Gray.—Flowers small, rose-coloured, with a yellow base. Southern Minnesota and South Ontario.

Group II.—Western species, with usually tall scapes, and inner petals with prominent gibbosities at the base.
* Style distinctly tricuspidate.

5. *E. grandiflorum*, Pursh., Lindl., *Bot. Rey.*, t. 1786.—Leaves not mottled. Flowers bright yellow, 1½ to 2 inches long. Idaho, Washington, and British Columbia. *Gardeners' Chronicle*, June 27, 1874, p. 831.
Var. *E. Nuttallianum*, Regel, *Gartenflora*, t. 6951; now R. and S.—Scape shorter. Flowers rather smaller. Northern Utah to British Columbia, more common than the type.

6. *E. Hartwegii*, S. Wats.—Leaves mottled. Flowers one to three to a scape, 1 to 2 inches long, pale yellow, with an orange base. Sierra Nevada of

California. See *Gardeners' Chronicle*, 1896, xx., p. 361.

7. *E. revolutum*, Smith.—Leaves mottled. Flowers bright mauve purple, 1½ to 2 inches long. British Columbia.

8. *E. Johnsoni*, Bolander.—Flowers bright purple. Southern Oregon. *Gardeners' Chronicle*, 1896, xix., p. 549.

9. *E. Bolanderi*, S. Wats.—Flowers white, with a yellowish centre, 1½ to 2 inches long. California, in the Sequoia region.

10. *E. giganteum*, Lindl., *Bot. Mag.*, t. 5714.—Scape tall, one to six-flowered. Flowers white, with a bright yellow or orange base, 1 to 1½ inch long. Lower Columbia, southward to Sonora and Mendocino Counties, California. *Gardeners' Chronicle*, 1894, xv., p. 621.

11. *E. montanum*, S. Wats.—Near the last, but more or less abruptly contracted or rounded at the base. Flowers white, with an orange base, often drying pinkish. High Mountains of Washington Territory and Oregon.

** Style not tricuspidate at the apex.
12. *E. citrinum*, S. Wats.—Scape three-flowered. Flowers light yellow, with an orange base, their tips becoming pinkish. Southern Oregon.

13. *E. Hendersoni*, S. Wats., *Bot. Mag.*, t. 7017.—Flowers purple, with a dark purple and yellow base. Southern Oregon. *Gardeners' Chronicle*, 1888, liii., p. 193.

14. *E. purpurascens*, S. Wats.—Scape one to eight-flowered. Flowers, ¾ to 1 inch long, light yellow, with a purplish tinge, deep orange at the base. Sierra Nevada of California.

15. *E. Howellii*, S. Wats.—Scape one to three-flowered. Flowers pale yellow, with an orange base, becoming pinkish. Southern Oregon. *J. G. Baker*.

GARDENERS' FRIENDS.

The Song thrush.

By HARRISON WEIR. (COPYRIGHT.)

THE SONG THRUSH, throats, mavis, grey-bird (*Turdus muscivorus*), if not the finest, is one of the finest of English songsters, all things considered, not the least of which is the length of time that he is "in song." Perhaps no other song-bird is better known among our British birds, nor more universally admired. With few exceptions, one of which is the robin, no bird sings so continuously as the thrush. Early in the spring, late in the autumn, and even in winter, when the ground is covered with snow, ever and anon his voice may be heard, strong, loud, sweet, and musical. Though, of course, there is a great similitude, still there is much difference in the arrangement, and in the number and variations of the voice, the sweetness of tone, and the general harmony, which may be noted by the clese observer. To some the voice is very loud and shrill, while in others [many of the cadences are] supremely soft, rich, and enjoyable. To none possibly is this better known than to the professed "bird-fancier." As one of these very quaintly remarked to me many years ago—"Some birds, sir," he said, "are worth their weight in gold, some a pound, some a shilling, and some not worth a song." At the present time, there is a remarkably fine songster that sings in a tall tree standing in my garden, early and late it affords me very great delight to listen to the various changes and complications of voice in which he constantly indulges. The thrush is a very early riser; as soon as it is light, or, I may say, ere daylight begins, he is out and about, and it is quite necessary that he should be, for he is one of those birds that not only wants, but gets, the proverbial "early worm." When it has been almost too dark to see distinctly the actual form of things, I have noticed the thrush and the blackbird peering about, with curious eyes, on the grass plot. A few hops, and the head descends; a quick succession of smart tugs, and out from his muddy hole is drawn a worm. It is dashed down, the bird looks at it, puts his foot on it, a tug or two, then more observations;

again and again the worm is dashed down, "thrown up, dashed down," and then a jerk, and it is gone. Another or two is sought for, found, killed, and swallowed. Then, perhaps, a snail, and breakfast is done. The thrush looks about, flutters his wings to shake off the dew, takes a few hops among the wet grass to clean his feet, and after cleansing his bill by transverse action on the wet grass, he mounts into a tree, then higher and higher, until he nearly or quite reaches the topmost bough, when he bursts forth into glorious song, "bidding the sun good-morrow." After a while, he again descends, more food is searched for; but in about twenty minutes he is up again, and there is a feed of far-reaching harmony. By this time, many other insect-eating birds are awake, and the "early worms" have a sad fate of it. Put the thrush is mute, and he descends among the boughs, and he will, after taking a little more food, compose himself for a short nap, when he suddenly awakes, looks about sharply and quickly, shakes himself, then away to some water—the edge of a pond or sandy side of a stream—and soon he will commence his ablutions, and after getting thoroughly wet will recline on his side, with one wing raised, and bask in the sunlight, enjoying the warmth, and also the comforts of cleanliness, then off and away to other feeding-grounds, and for other kinds of insect-food. If it is the breeding season, and the hen is not sitting, she is generally close at hand, and sometimes the cock-bird will look for and put before her one of his best finds in the way of worms. The snails are taken to a particular stone, and then Master Greybird hammers off the shell, and with the look of a gourmet—"he feeds." The thrush seems to remain paired during the greater portion, if not the whole, of the year. I have certainly seen them so, late in autumn, and very early in spring, as well as in summer. The hen much resembles the cock, though less bright in colour; this varies so very much, that in some districts or localities a hen bird may be brighter in colour than cock birds in others. Having been one of the judges at the Crystal Palace bird shows for many years, I have had ample opportunities of comparing different birds of much excellence in every way, and it has been a matter of deep interest to me to observe the varied forms and tints of brown and orange there shown—some having the spots on the breast black on a white ground or ash colour, others deep chocolate on an orange ground, the other parts corresponding. Some are large, and thickly made, others slim, and finely formed, with colours of great richness. While on the subject of markings and colour, it will not be out of place to say that on one occasion I had a nest of young thrushes offered, the whole five of them were entirely white. I have also seen fawn coloured specimens; and for some time there was one in my garden that was much splashed and marked with white. The white birds show the spots and markings by the different formations of the web of the feathers in the same way that the spots are clearly visible on the tail of the white peacock.

A few years since, when with Mr. R. D. Blackburne, the author of *Lorna Doone*, who, besides being so talented a novelist, is also a great bird-lover, and a close observer of Nature, he informed me of a very curious thrush, of the ordinary colour on the back, head, and tail, but the breast was a light ash tint, without any spots thereon. It was not in confinement, but in common with others and some blackbirds. It was very tame, coming to be fed from the hands of Mr. Blackburne. This is the only specimen I ever heard of without spots on the breast, the other parts being of the usual colour. He also mentioned some curious blackbirds, to which I may refer subsequently.

The thrush breeds very early in the year. I was informed in March this year of a nest with five young ones, and have known of nests and young at the end of February. The nest is built of dried grass roots, and moss, lined with clay. The eggs are generally a bluish-linen green, spotted sometimes heavily at one end with black, at others lightly all over; and I have seen them quite blue, without a spot, in the same nest with others spotted or lightly marked.

COLONIAL NOTES.

NEW HEBRIDES.

I enclose herewith for your examination a specimen of *Agathis obtusa* (Dammara), with male catkins (fig. 103, p. 301), a species that is not likely to be common in collections. It was obtained on the island of Aniteum, New Hebrides, where a saw-mill has been in operation for some years, though, from all accounts, at a pecuniary loss, attributed by many to the company sending out imperfectly seasoned timber. The humid climate, however, may have some influence in retarding the seasoning. Unfortunately, I did not secure any female cones. There seems to be a good deal of difference of opinion among systematic writers as to the number of species of *Agathis*. The shape of the leaves does not appear of a reliable character, as those of a tree in the Sydney Botanic Garden are larger, less stiff, and less rounded at the apex than those of the specimen sent you, while the latter show among themselves a tendency to form a point. I enclose also a photograph of one of the largest of the trees (fig. 102), which measured 23 feet 9 inches in girth at 5 feet from the ground.

[Of this species, formerly known as *Dammara obtusa*, Mr. C. Moore writes: "The habit of this species, and of that found upon Vanikollo, is very similar to the *Kaurie* of New Zealand. In whatever situation I found them, they were invariably the monarchs of the forest; the stems of all three are robust and erect, throwing out branches from 30 to 40 feet from the ground, the branches spread out considerably, but all have a stiff, rigid appearance."]'

It was at the suggestion of the late Baron Von Mueller that I went last winter to the New Hebrides to collect botanical specimens. The Baron thought new species might be found on the summits of the hills on these islands. Specimens were obtained up to 2700 feet elevation above sea-level, but a preliminary examination, as far, at least, as the genera are concerned, made at the Melbourne Herbarium, with the help of Mr. Luchmann, who has succeeded the late Baron there, seems to point to the conclusion that the flora of the group is chiefly composed of plants derived, probably, from the other islands of Oceania and from Eastern Australia.

Fromanga and Efaté were examined, but the higher mountains on the more northern islands may possibly yield greater novelties. *Atca Morrison*.

MANCHINEEL (*Hippocane Mancinella*, L.).

The fruits or Apples of the deadly poisonous Manchineel are now (April) seen strewn along our seashores—Grenada—in great quantities, and also floating about on the surface of the sea to be drifted in the course of time by currents of the Caribbean Sea, and cast ashore on distant islands and countries. But long ere they reach their goal, the fleshy portion of the fruit will have either rotted away by the action of the salt-water or been nibbled by fish, leaving but a skeleton-like shell, wherein lie the few small seeds. Mr. Lunt, of the Trinidad Botanical Department, when recently engaged upon the successful rediscovery of *Saccoglottis amazonica* in Trinidad, gave it as a fact from observations made by himself last year, that bats were the agents that reduced the famous drift fruit to its skeleton condition by their feeding off the fleshy portion of the fruit. The Apple of the Manchineel is very much like the wild English Crab Apple of English coppes in shape, size, colour, and smell, and sailors in their wanderings have often suffered through this similarity, not knowing the danger of this deadly sea-fruit, and in some cases their eating of it has caused death. In cutting any portion of the tree, a virulent white milk flows out, and if by chance it settles on the skin blisters it, and sores will follow within a day or two after. Salt-water, which is always near by, is said to be an antidote. This is hardly my experience, for I found upon one occasion in particular, that, although I bathed in the sea shortly after getting a little of the milk on my body, the blisters and sores appeared two days subsequently. Some of our people before planting their Indian Corn seed (Maize), usually put it into a calabash, and gashing the bark of a large

Manchineel tree, allow the milk to drop over the corn so as to prevent rats eating the grain after it has been sown, for, as elsewhere, rats are among our many pests. The drift-seeds met with upon our shores are chiefly *Saccoglottis amazonica*, *Manciera saccifera* (the sea Gra-gra), *Terminalia catappa* (Almond), and the Manchineel. *W. E. Broadley, Grenada*.

LOCAL DESIGNATIONS.

"We are unhappily flooded with local designations, made up by anybody, anyhow, and applied in the loosest way, quite haphazard. Does a native Cape plant come into notice for good or for evil? The chances are that someone calls it by the name of some

In the next division, *Tarchonanthus*, a composite little tree, is "Wilde Salie," in virtue of its having a crinkly, rugose leaf. Elsewhere a similar sort of foliage earns the title for *Buddleia salviafolia*. And it becomes a little perplexing to have to correspond and explain on the basis of these names about the presumed medicinal virtues of, say, *Wilde Salie*, which may be any one out of the three. The writers argue each for the absolute correctness of their nomenclature, and resent being told what *Salie* is, and what a *Thistle* ought to be. They have heard the plant so called from their youth up, therefore it is correct, and all other names are wrong." *Report of the Government Botanist, Cape of Good Hope*.

FIG. 102.—*AGATHIS OBTUSA* IN THE FOREST OF ANITEUM.

(From a photograph by Mr. Morrison.)

perfectly different English plant. This is thought to be giving it an English name, and making it easily recognisable by English people. The resulting confusion is distracting. A Mexican Poppy (*Argemone mexicana*) springs up on the spoil-heaps at Kimberley from a chance seed, and increases so fast as to become a nuisance. It is feebly prickly, hence is dubbed by some careless person a "Thistle." The next man calls it a "Scotch Thistle," imagining that Scotland has a monopoly of these things, and that every Thistle must be Scotch. Next, the ridiculous misnomer gets upon the minutes of municipal boards and divisional councils concerned in a crusade against weeds. After that the chances of the Poppy holding its own are few and small—it becomes a Scotchman naturalised by force. With local names in the "taal" of the country the case is much the same. In one place, the appellation "Wilde Salie," is quite properly applied to *Salvia clandestina*, a true Sage.

THE ROSARY.

A FEW REALLY GOOD NEW ROSES.

ALTHOUGH somewhat late in the season for planting Roses, from the fact that almost all of our newer and scarce varieties are grown in pots, and can, consequently, be planted out at any time of the year, one may still add any or all of the following to their collections. There are a great number of new Roses, but I propose to confine myself to six from each of the three chief classes, viz., the Hybrid Perpetuale, Teas and Noisettes, and Hybrid Teas.

Hybrid Perpetuale.—Bladud, a magnificent bloom during a cool and dry season, the flowers of much the same form as in *Mdlle. Bonnaire*, but in every way twice the size. The colour is a silvery-white, with a delicate pale blush in the centre; particularly good in the autumn. Laurence Allen, a very promising

new Rose, somewhat resembling in habit and form *Brocree* Rothschild and Spenser, but having greater depth of colour and a better form. I know of no Rose with a more agreeable fragrance, which in itself is a great recommendation, especially among pink Roses, a class that is peculiarly deficient in this respect. Mrs. Ramsey is another fine addition to pink Rose, very free blooming, each flower borne upon strong shoots, the foliage of an intensely green tinge; it has the merit of being mildew proof. Helen Keller, a variety which gained the National Rose Society's Gold Medal, has blooms of ideal shape, fair size, and distinct colours, a bright rosy cerise: the plant grows with vigour. Elfen Draw is a sport from *Duchess de Morny*, possessing the good characters of that splendid Rose, differing only in being a light silvery pink, with peach shadings; all rose-growers will recognise its value.

larger, fuller, and brighter. *Beauté Lyonnaise* is white, upon a slightly yellow-tinted ground, very large and full. *Alcée Furon*, a large globular flower, yellowish-white, correctly described as an improved *Gloire Lyonnaise*; the beautiful dark green foliage keeps clear and handsome throughout the season. *Charlotte Gillemot* is a distinctly imbricated blossom, with large, thick petals; colour clear, French white, described by some as clear ivory-white—a really good new Rose.

Teas and Noisettes.—*Muriel Grahame* is a sport from *Catherine Mermet*, which has already given us several valuable additions, in *The Bride*, *Waban*, and others. The only distinction is, that it is a very pale cream, slightly flushed with rose; and we do not find it quite so full, as a rule, as the majority of *C. Mermet* blooms, but some grand examples occasionally appear. *Bridesmaid* is another sport from *C.*

more that are well worth growing, but I believe the above eighteen to be the pick of those sent out in 1895, 1896, and 1897. *Maman Cochet*, Mrs. W. J. Grant, Marchioness of Downshire, and others from their respective classes, were distributed one year previous to those named in my list. An exception is made in Mrs. R. G. Sharman-Crawford, on account of its extra sterling qualities in a class where really good new Roses have been scarce of late years. A. P.

MUMMY ROSES.

From the *Compte-rendu* of the Séance of Nov. 10, 1888, of the Société Royale de Botanique de Belgique, we abridge the following account of the remains of Roses found in the tombs of the necropolis of Arsinoë of Fayoum (Egypt). The writer, M. François Crépin, mentions that, in the previous June Dr. Schweinfurth sent him word from Cairo of the discovery of Roses in Egyptian tombs, and that these fragments had been sent to London. It was from Professor Oliver that some specimens were sent him from Kew for examination. These samples included nine flowers on their stems, the petals were fallen and mixed with the stamens and anthers. All nine flowers came from the same variety or species.

So far as could be judged from such imperfect specimens, their closest affinity was with a Rose cultivated in Abyssinia, in the Tigris province, around churches or other religious buildings. Specimens of this Rose, gathered by the French travellers Quartin-Dillot and Petit, had been described by Ach. Richard under the name of *Rosa sancta*. Richard stated that *R. sancta* resembled *R. centifolia* in appearance, but differed by its glaucous, glabrous, and glandless branches, furnished with a small number of slender and curved thorns, and by its much smaller flowers. The resemblance traced by Richard appears warratable by the fact that *R. sancta* seems to belong to the *Gallica* section. It is probably a variety of *R. gallica*, and not a native of Abyssinia, but a cultivated form introduced into the country many years ago. So far, among the many varieties of *R. gallica* now grown, no form is exactly like that of *R. sancta*.

To return to the Rose from the Egyptian tombs, which seems more nearly to resemble *R. sancta*. There is reason to suppose that it came from plants cultivated in Lower Egypt, and perhaps even from near the locality where it was discovered. The Egyptians cultivated Roses largely, and supplied them to Rome during the winter previous to the invention there of greenhouses. This mummy Rose is no more indigenous to Egypt than is *R. sancta* to Abyssinia. It might have been imported from Italy, Greece, or Asia Minor, where *R. gallica* is indigenous. Egypt has no indigenous Roses, the nearest place to find them being the Abyssinian mountains, where grows *R. abyssinica*, a variety of *R. moschata*.

Dr. Schweinfurth comments upon the interest of these comparisons. Mr. Flinders Petrie showed him some fragments of Roses which he had found in the necropolis of the town of Arsinoë, Fayoum, near the pyramid of the Labyrinth, and which were strung on a ring like a thin garland of the first and second centuries after Christ. These were the same tombs wherein were found certain interesting portraits in coloured wax. [Messrs. Paul & Son of Chestnut, have plants of *R. sancta* in their nurseries. Ed.]

FIG. 103.—MALE CATKINS AND SHOOT OF *AGATHIS OBTUSA*. (SEE P. 300.)

Mrs. R. G. Sharman-Crawford is another grand Rose. Once I described it as being likely to rival Mrs. John King very closely, and lately I have more than once written that some persons prefer it to that beautiful variety; it is quite rose, with a distinct form and colour, of good habit, very free blooming, a deep silvery pink, with flesh shadings outside. All of the above six were raised in this country.

Hybrid Teas.—*Majorie* is a free and compact grower, one of the best Roses for cultivating under glass, every flower coming perfect in form, but in size rather small, according to the present-day standard; the colour is a soft creamy-white, suffused with salmon-pink, and it is a very floriferous variety. *Antoine Rivoire*, one of the grandest hybrid Teas we have as yet received from Messrs. Pernet Ducher, a plant of a vigorous habit, free flowering, of large size, good form, rosy flesh shade, with yellow ground, and bordered with carmine; a particularly striking bloom, and one that is sure to please. *Clara Watson*, a good grower, deep salmon and pink shade, after the style of *Souvenir de Paul Neyron*, but much more reliable,

Mermet, of a deeper colour than the parent form. Occasionally a flower of the type comes equally bright, but *Bridesmaid* may now be considered a fixed sport. *Sylph* has a flower with a high centre, and large stiff petals, slightly tinted with violet and peach. The bush is a good grower and a free bloomer, especially when grown under glass. Mrs. Pierpont Morgan is a very bright, larger, and altogether improved form of *Madame Casin*. It has been good here; and we also have such high authority as that of Dean Hole respecting its great usefulness and beauty in the United States, from which it was distributed. *Souvenir de Catherine Guillot*, although not yet seen sufficiently large and heavy for the exhibition-box, is a beautiful and distinct Rose; a yellow ground, tinted with carmine and orange-red, quite a unique combination among Roses. *Fiametta Nabonnand* originated from crossing *Niphotes* and *Papa Gontier*, the result being a long petalled flower, white, tinted with carmine—a very pretty bloom, and owing to its free-blooming and excellent growth one that is sure to be much liked. It would be easy to name several

TREES AND SHRUBS.

CYTISUS PRÆCOX.

ALTHOUGH, curiously enough, mention of this Broom has been omitted from nearly all the popular works of reference, there is none among the early-flowering *Cytisus* which better deserves cultivation. It is a hybrid obtained by crossing *C. albus* and *C. purgans*, but by whom or at what date the cross was effected, I have not been able to ascertain. It has been in existence for more than twenty years, at any rate. It commences to flower in mid-April, about the same time as *C. purgans*,

but is considerably in advance of the other parent—*C. alius*. It is a shrub of graceful habit, producing a mass of slender, wiry shoots, sparsely furnished with simple linear leaves, half an inch or so long, and covered with a silky pubescence. The branches made last year are now covered with sulphur-coloured flowers in a profusion scarcely equalled by any other *Croom*. It is now a conspicuous feature at Kew, several large masses of it being in full flower. If it has one drawback—it is the powerful and none too pleasant odour of the blossom. It ripens seeds freely, but only a small proportion of them come true; some revert more or less to the golden-flowered *C. purgans*, the majority simply producing *C. alius*. It can best be propagated by putting in cuttings during August in very sandy soil, under a bell-glass, in some sheltered corner, or in an unheated frame. The plants should frequently be shortened back when young to get an abundance of branches near the ground, and thus delay as long as possible the lanky character it eventually assumes in common with all the taller *Cytisus* and *Genistas*.

CYTISUS ARBOREUM.

This is the earliest of the dwarf semi-prostrate species of *Cytisus* to burst into bloom, and it is now covered with its rich golden-yellow flowers. As a plant for the rock-garden, or for furnishing the ground beneath taller shrubs, it deserves especial notice. We use it in both these ways, and in the latter case it is planted in a bed beneath some *Caragana*, whose thin foliage admits sufficient sunlight to allow it to thrive. This is a point to be remembered, for it is by no means a shade-loving plant. It rarely grows more than from 6 inches to 12 inches high, its tiny trifoliate leaves being downy, and the leaflets ovate. Although McGrizgo was not the first to discover it, he was the first to bring it into notice by figuring it in his *Flora of Mentone* in 1871. It was found by him at the top of Mount Cima d'Ours near Mentone, to which, along with two other mount in summits near that town, he states that it is confined in a wild state. It is rarely found bearing seed in its native home, owing to the continual nibbling of the shoots by animals, which perhaps explains its rarity as a cultivated shrub. It can, nevertheless, be recommended as one of the most beautiful of its class, being perfectly hardy, and valuable as flowering so early as April.

BERBERIS STENOPHYLLA ×.

The work of the hybridiser amongst hardy shrubs has produced many beautiful things, but in none perhaps has his ideal—which is the production of a plant distinctly better than its parents—been so notably achieved as in this *Berberis*. It is a cross between *B. Darwinii* and *B. empetrifolia*, and was first sent out, I believe, from the well-known Hands-worth nursery of Fisher & Holmes. So distinct is it, that doubts have frequently been expressed as to its origin, but there is sufficient proof of this in the fact that it rarely comes true from seed, reverting generally to *B. Darwinii*, and occasionally to *B. empetrifolia*. At the present time it is one of the most beautiful shrubs in bloom. The long arching branches, thickly set with linear, mucronate leaves, half an inch long, and of the deepest green, are now transformed into wreaths of rich yellow blossom. Some of the shoots are 2 feet long; the nodes are half an inch apart; and as ten or a dozen flowers are produced at each node, some idea of its free-flowering nature may be conceived. Not only is it a much more graceful plant than *B. Darwinii*, but it is also harder. I have never seen it damaged in the slightest degree, even by the severest of frosts in the London district, which is more than can be said of *Darwinii* or *Berberis*.

PYRUS FLORIBUNDA.

This is the proper name for what is commonly known as *Malus floribunda* and *Pyrus malus floribunda*. Along with *P. spectabilis* it is the loveliest of the numerous *Pyrus* now in bloom. Of many glorious shrubs we owe to Japan, there are few that

can claim a greater share of our admiration and care than this. Just now, when half its myriad pendent blossoms are open, and the other half still in the bud-state, its beauty, perhaps is greatest; for the open ones are of a soft pale rose, whilst intermingled and contrasting with them are the jewel-like buds, whose unfolded petals are of a deeper, richer hue. There are now several varieties of this *Pyrus* in cultivation, the finest of which, probably, is *atro-sanguinea*, whose flowers, even when fully open, are of as rich a rosy red as the buds of the type. The double-flowered variety (*dors-pleno*) is generally called *P. Parkmanni* or *P. Halleana*; it may possibly be a hybrid between this species and *P. spectabilis*. The shrub set out from the Continent under the name of *P. Schiedeckeri* is also a form of this species. W. J. B.

NURSERY NOTE.

CINERARIAS AT FARNHAM ROYAL.

ANTHONY reference to these beautiful spring flowers becomes an all-the-story, yet it is impossible to see them in all their variety, numbers, and effectiveness as I saw them recently, without feeling that they merit all possible publicity. The collections of several dozens of plants sometimes seen at the Drill Hall, always make their mark, and attract full attention; but at Farnham Royal I saw but the other-day enough of plants, all of about the same dimensions, and all in 6 inch pots, to quite fill the Drill Hall, and if so exhibited they would constitute a splendid show. It is better to see the collection when all the diverse hues of colour are selected and grouped, for the big masses of hundreds of plants produce a fine effect. Altogether there were some 2,800 in all in full bloom, probably the largest, as also the best, collection of the garden *Cineraria* in the kingdom. There are blocks of pure white, and grand blooms too; cerise, magenta, red, deep red or crimson, purple, blue in shades—some light, and some very deep and rich. Then come batches of plants with edged flowers, the margins being generally broad and striking. This is a peculiarly effective section, the heavy hues being so pleasingly lit up by the white centres or rings. There are at this time of the year in greenhouses few floral sights which so well repay a visit as do the *Cinerarias* which Mr. W. James has this season. I noticed that he has a break from crossing *Cinerarias cruenta* and *lanata*, the plants about 18 inches in height, and some of these show a pyramidal branching form that is distinct and pleasing. A. D.

THE WEEK'S WORK.

THE KITCHEN GARDEN.

By W. POPE, Gardener, Highclere Castle, Newbury.

Brussels Sprouts.—This vegetable is in most gardens one of the most important autumn and winter crops, and the time has arrived when good breadths of those plants that were raised from seed sown inside may be got out. In most south country gardens the plants that were sown and forwarded under glass for a time will have been already planted, and will be making progress. Let the ground be stirred frequently with the hoe, and as the stems lengthen, afford them a slight earthing-up, which will steady them, and prevent wind-waving. In some much-exposed gardens it is advisable to place a stake to every plant, securing them with broad bast ties. The most suitable quarter in the kitchen garden for the main crop is that which is of good depth, has been heavily manured, and deeply trenched, and that has not carried a crop of the Cabbage tribe for two or three years. If the land be not firm, it must be made so by tramping it, a loose soil invariably meaning loose, soft sprouts. Let the plants stand from 2 to 2½ feet apart each way, according to the nature of the soil, or the size to which the varieties grow, on strong land the wider distance being advisable for all. For affording a late supply of plants, seeds of a good strain of imported or the Covent Garden variety may now be sown.

Savoy and Kale.—Seed may now be sown of Dwarf Curled and Drumhead Savoy, and any of the small early varieties that may be deemed desirable. For small gardens the Tom Thumb and Early Ulm Savoy are useful ones, as they can be planted thickly, and on the score of good quality they leave nothing to be desired. Sow thinly, and do not allow the plants to become crowded in the seed-bed before planting out. Of the varieties of Kale, none is more generally useful than the Curled Scotch, especially the dwarf form of it, with the Jerusalem or Asparagus Kale for late use. [Those who have ground to spare should sow the Braganza Cabbage, Couve Trubuda. It is not very hardy, but it is delicious eating, and can be had in perfection up to December. Ed.]

Tomatoes for Planting Out of Doors.—These should now be in a cool frame with plenty of air afforded by day, drawing off the lights entirely on bright days. Secure each plant to a stake, and avoid crowding. When planting, press the soil very firmly about the balls, and afford water carefully till the roots have taken possession of the new soil. Remove the lateral shoots as fast as they appear, keeping the plants to one stem.

Vegetable Marrows and Ridge Cucumbers.—Plants raised in heat, but grown lately under somewhat cooler conditions may now be put into their summer quarters. A mild hot-bed is requisite to give them a good start, and they should be covered for a time with hood-lights, or some form of glass protection, and night-coverings afforded for a few weeks. Seeds may now be sown under the same conditions if plants from early sowings are not available, a brisk bottom-heat and top protection being required.

Turnips.—Thin the out-door Turnip crop as soon as the plants are large enough to handle, leaving them a little closer than is desirable for a crop, and thinning finally a few weeks hence, or they may be dropped out into clumps, with the hoe, and thus left in bunches 8 or 10 inches asunder, the surplus plants being pulled out after. Dust the plants over with fresh soot, or soot and lime, or spent Hops, as a means of securing the Turnip-fly. When sowing after this date, apply a little superphosphate of lime in the drills with the seed, it will accelerate growth, and help to push on the plants at that stage when the fly is most troublesome.

THE FLOWER GARDEN.

By CHARLES HERRIN, Gardener, Drogheda, Maidenhead.

Dahlias.—Plants recently struck in small 60-sized pots should be given a shift if likely to become unduly root-bound, as another fortnight must pass before it is safe to plant these out in the borders. Remove the lights in warm weather from the frames in which they are standing. Old roots that are merely split up before planting, and have been kept almost dormant up to the present, may be put out about the middle of the month. These will furnish useful flowers in quantity, but the newly-propagated ones will give the best. A mulch of rotten manure is advisable for Dahlias after planting, and especially so if the soil is of a light nature. For garden decoration the free-flowering Pompon varieties are most telling, and several together of one variety producing masses of colour have a better effect than too many colours. The following are six good Pompons, White Aster, white; Isabel, bright orange scarlet; Fhebe, deep golden orange; Mars, bright scarlet; Nerissa, soft silvery-rose; and Douglas, deep maroon. For use as cut flowers no section is equal to the true Cactus type, these having the advantage over the single varieties of lasting longer in good condition. In the garden, perhaps, their worst feature is that they fail to throw the flowers well above the foliage, but by a system of disbudbing this may in some measure be avoided, and those most subject to this failing should be omitted. The following comprise some of the best for general purposes. Of new ones, Mrs. Wilson Noble, pinkish salmon, free; Mrs. Francis Fall, white; Harry Stradwick, dark crimson-maroon; Mrs. Barnes, pale primrose, tipped pink; Harmony, reddish-brown, yellow centre; Mrs. Montefiore, crimson scarlet; Fusilier, salmon pink. Good older varieties are, Bertha Mawley, cochineal colour, very free; Delicata, soft pink; Matchless, velvety maroon; Lady Penzance, sulphur yellow; Gloriosa, bright red, rather tall grower; Ernest Cannell, red; Mrs. A. Peart, creamy white; Mrs. Turner, deep yellow; Robert Cannell, magenta; Countess of Radnor, delicate salmon; and the old Juarezit, bright crimson.

Alpine Aucubias.—These pretty spring-flowering plants are useful for small beds or borders, and seeds

may be sown now for raising plants to flower next year. From a packet of good seed a great variety of colours may be obtained. As the seeds often germinate slowly and irregularly, they are best sown in boxes of rather light soil, just covering the seeds, afterwards standing in a cold frame where shade may be afforded until the seedlings appear. The soil should not be allowed to become dry. Old plants may be pulled in pieces as soon as flowering is over, and be sown in, in some shady spot, and these will make strong plants for another season, larger than those raised from seeds now.

Primrose and *Polyanthus* may also be raised from seed forthwith, to flower next spring. A shady border or frame on a slight hobble will be a suitable position for sowing the seeds, scattering them thinly in shallow drills, drawn up a few inches apart. Any special varieties now in bloom, of which it is desired to save seeds, should be marked, and if possible, isolated from others.

THE HARDY FRUIT GARDEN.

By H. W. WARD, Rayleigh, Essex.

Wall Trees.—The thinning, pinching, and training of young growths upon wall trees require almost daily attention at this season. Especially is this the case in regard to young trees in order to obtain symmetrical well-trained trees that will cover the space allotted to them on the walls, and yield profitable crops of fruit in as short a time as possible. Strict attention must be given to details of a routine character, retaining only as many young shoots of the current year's growth as are absolutely necessary for the formation of the principal trees, rubbing out in the bud state the surplus growths of Peach-trees, and pinching those of Apricots, Plums, Pears, and sweet Cherries not required for the building-up of the trees, back to one well-developed leaf, which will promote the formation of fruit-buds. The points should be pinched out of any growths which are likely to rob the weaker ones. The young growths that are to be retained should be trained at equal distances on the wall in the manner recommended in a previous Calendar. Young shoots of Peach-trees and the Marcella Cherry should be kept in between the several pairs of branches with twigs, taking care not to injure them in doing so. The object should be to encourage and maintain a free healthy growth in the trees. It will be necessary to keep the soil moist about the roots, and to prevent the shoots and leaves from attacks of aphids and mildew. Weakly growing trees and plants, like animals, are more subject to the attacks of disease or pests than those of an opposite description; consequently, the trees must be constantly observed during the whole of the summer months, and prompt action should be taken upon the first appearance of either aphids or mildew, by pinching the affected trees in the afternoon with the solenons recommended in the *Gardener's Chronicle* for April 17 last. In order to prevent attacks of red-spider, as well as to promote a free, healthy growth in the trees, Peach-trees should be well washed with clean water, applied from the hand garden-engine (every afternoon on bright warm days.

Frost Blinds.—The cloths with which the blossoms of Peaches, Green Gage Plums, and choice Pears have been protected, together with the poles, coping-boards, &c., should be removed forthwith.

THE ORCHID HOUSES.

By W. H. WURR, Orchid Grower, Harford, Dorset.

Succuladums.—In the case of plants of *Succulobium Blumei*, *S. giganteum*, *S. guttatum*, *S. celeste*, *S. retusum*, *S. pumosum*, *S. violaceum*, and the white *S. Harrisonianum* in a weak condition, it is advisable to remove the flower-spikes as soon as they appear, and to give the plants generous growing treatment. It is also a good plan to remove the sphagnum-moss from the plants, and to fill up the space with clean crocks. Suspend each plant near the roof glass in a moderately shady position, and each afternoon when the house is closed and the lamps down pour plenty of water through the crocks, and well moisten the roots that are clinging to the exterior of the Teak wood basket.

Evergreen Calanthes.—*C. veratrifolia*, *C. musca*, and *C. Donnelliana* must be constantly examined for insect pests. Brown scale is apt to be troublesome at this period, and if not checked will cause some injury to the foliage and flower-stems. If any green and yellow aphides are detected, place the plants in some house which is being fumigated. Specimens of these Calanthes that are in a weakly condition should

be believed of their flower-spikes as they appear. The proper time for reporting such Calanthes is immediately after the flower-spikes are cut. But the present is a good time to report unhealthy specimens from which the spikes have been removed. They require rather large pots, and these should be about one-third filled with crocks, over which a thin turf of loam with the grassy side downwards should be placed. The compost should consist of fibrous yellow loam, with the addition of a little leaf-soil, coarse silver-sand, and small pieces of charcoal or broken crocks. Pot the plants moderately firmly, allowing about half an inch of space below the rim of each pot, to permit of efficient watering. They should be grown in the intermediate-house, but they will also grow vigorously in the ordinary stove. Place them in a shady part of the house, and where they may obtain a moderate amount of fresh air daily. Plants of the hybrid *Palmis Cooksoni* and *P. Marthæ*, that have recently passed out of bloom, should be kept in the intermediate house until growth recommences. Allow the plants to rest as long as possible by keeping them moderately cool, and give only a sufficient amount of water to keep them plump; they will then start away strong and produce back breaks with greater freedom than when subjected to strong heat continually. *P. tuberosus* often suffers from small yellow thrips; these tiny insects frequently obtain a foothold low down in the young growths before the grower is aware of their presence in the house. Now that this pretty species is starting to grow, the new growths should be closely examined every day, and if any thrips make their appearance, the XI. All-supper should be employed for their destruction. Before the new growths commence to emit roots, the plant may be afforded fresh rooting material. Shallow pans or Teak wood baskets may be used, and should be two-thirds filled with drainage, over which a thick layer of sphagnum-moss may be placed; afterwards, a layer of peat and moss, upon which the pieces of the plant should be placed, filling up closely to the rhizome with fresh growing heads of sphagnum. Place the plants in a moist shady corner of the hottest house, and keep the compost moist at all times. A slight dewing overhead at closing-time will conduce to strong growth, and also check the attacks of insect pests.

FRUITS UNDER GLASS.

By F. HARRIS, Gardener, Easton Castle, Ledbury.

Cherries.—The very early trees in pots on which fruit is nearly or quite ripe, must be kept moist at the roots, but not to be subjected to overhead syringing, this being generally discontinued as soon as the fruits begin to colour, otherwise there is danger of the fruits splitting. In any case this is noticed before the trees are put in air and syringing water at the roots to keep the fruits plump, and to enable them to ripen properly. The s from which the fruit has been gathered should be removed to some sunny spot out of doors, and plunged to the rim in the soil, taking precautions against worms entering the pots. Such plunged trees must be afforded abundance of water at the roots, and a good syringing in the afternoon on sunny days, so as to keep the foliage from till it drops. Later successions of Cherry-trees under glass should be closely inspected once a week at the least for maggot and black aphids, the last the worst pests that affects Cherry-trees. The best remedy against these aphides is syringing with tobacco or quassa water, as it requires such a large quantity of tobacco-smoke to kill them that it injures the trees. [In the XI. All-Vaporic is excellent for the purpose. Ed.]

Plums.—The above remarks concerning Cherries apply also to the Plum, the only difference being that the fruit requires a longer period of time to ripen. Afford manure-water occasionally to trees in pots, and syringing the heads till the fruits exhibit traces of colour, when it must be discontinued. Let the lateral shoots be stopped at the second or third leaf from the joint, and also the points of any leading shoots which are growing too vigorously; or stop them back to a larger shoot that is well placed, and let this serve as the leading shoot.

Pines.—The early Queens are now ripening fast, and should be kept dryer at the roots as soon as colouring is noticed in the fruits, manure being no longer applied. If the ripening of the fruits is proceeding too fast, or there are too many buds together which have reached their full size, some of the forwardest may be placed in an early vinery where they will ripen properly if care be taken that they are not supplied with much moisture at the

root. Any plants carrying ripe fruits may be moved to a cool shed, or the Grape-room, where they will keep in good condition for a week or longer. Plants that have gone out of flower may be assisted by liberal supplies of liquid manure when they require water at the root. Be sure that the bottom heat is maintained at 85° to 90°, any check at this stage causing a loss of size in the fruit. Maintain a moist state of the atmosphere by damping walls and the surface of the bed, but not the plants, except on very bright days, when very fine dewing overhead may be afforded at closing time. Let all fruits inclined to topple over be properly supported before the crowns get awry; and all superfluous suckers not wanted for increase be twisted off.

Tomatoes.—The fruits should be removed as soon as they are completely coloured, so that the later ones may increase in size rapidly. Remove all the lateral shoots, nipping them back to one leaf from the stem if the plants are grown on single stem. A lateral shoot coming out near the bottom may be left to cover the bare stem. The plants are grown on a trellis, and allowed to spread; the shoots may be trained in thinly, and if the foliage is very dense, a portion of each leaf may be cut off. As the crop of fruit increases, afford frequent top-dressings and weak liquid-manure as often as water may be required. If the later plants have been prepared as directed in a previous Calendar, plant them without delay where they are to fruit. Such plants will begin to fruit shortly after planting. Plants intended for out-of-door fruiting should be removed into cooler quarters, and gradually hardened off in readiness for planting towards the end of the month. Seeds may be sown in order to raise plants to succeed the earliest fruiting-plants.

PLANTS UNDER GLASS.

By G. H. MAYCOCK, Gardener, Laton Hoop Park, Luton.

Chrysanthemums.—The plants intended for flowering in the late autumn should be potted for the last time as soon as possible after this date. For most varieties, pots of 9 inches in diameter are sufficiently large, and these must be new ones, or others made clean by washing, and be well crocked, although numerous crocks need not be used; and the best soil are those that are convex, which would be laid to concave side downwards, evenly, not thrown in at random—a depth of 2 inches will suffice, and over them should come a layer of bits of turf-leaf. The potting must be done firmly, a wedge-shaped rammer being made use of for making firm the soil between the ball and the pot towards the bottom; and but a small quantity of soil should be placed in the pot at a time. If the potting-soil was mixed up as advised it will now be in good condition for use. All the repotted plants the protection of a cold-frame for a week afterwards, and syringe the tops occasionally during the early part of the day. If, however, for want of space, the plants must be placed out of doors, a temporary shelter should be provided for them, and it is well to take the precaution to stake each plant before it is removed from the potting shed.

Green Work.—A sowing of Mignonette seed may be made in pots, so as to form a succession to the earlier sowing, and if these are 2 flower 2 inch pots, let the lateral growths be pegged down to the soil in a circle, and these will furnish good spikes of bloom. The flower spikes should be pinched off zonal Pelargoniums when small, if the plants are intended to flower during the winter months. Palms should be kept well watered, more air allowed, and plenty of water afforded the soil, pot-but not plants being supplied occasionally with liquid manure. Divided *Aspidistra lurida*, when re-established, should be removed to a cool-house or low pit, placing them where they will receive some amount of direct sunshine.

TO DRIVE AWAY ANTS.—Probably pharmacists are more often consulted on a means to drive away ants than on any other entomological subject, excepting the ever present "blackbeetle," which is with us always. We have found that a solution of naphthalin in carbon bisulphide is excellent for outdoor use, but is of course too dangerous to use indoors. For use in the house, a saturated solution of naphthalin in carbonic acid is almost equally efficacious. Bisulphide is also effectual for destroying moles on lawns, and for suffocating wasps. It should be poured down the entrance to the nest at night, and the orifice immediately closed with a clod of earth. *Journal of the Pharmaceutical Society*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER. Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on ONE SIDE ONLY OF THE PAPER, sent as early in the work as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY,	MAY 8	Royal Botanic Society, Meeting.
TUESDAY,	MAY 11	Royal Horticultural Society's Committees.
WEDNESDAY,	MAY 12	Exhibition of Tulips and Conference at the Royal Botanic Society's Garden (two days).
SALES.		
MONDAY,	MAY 10	Bedding Plants in variety, Greenhouse Plants and Ferns, Carnations, &c., at Protheroe & Morris' Rooms.
WEDNESDAY,	MAY 12	Japanese Lilies, Calceolarias, Tuberoses, Dahlias, Pinks, &c., at Protheroe & Morris' Rooms.
THURSDAY,	MAY 13	Established Orchids; also Importations of Orchids, Bulbs, Lilies, Plants, Palms, &c., at Stevens' Rooms.
FRIDAY,	MAY 14	Established and Imported Orchids, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—53°.

ACTUAL TEMPERATURES:—

LONDON.—May 5: Max., 59°; Min., 45°.

PROVINCES.—May 5 (6 P.M.): Max., 55°; E. Counties: Min., 42°; Sumburgh Head.

THE main interest in matters horticultural this week is centred in Germany. Both at Hamburg and at Berlin vast exhibitions are in progress. Of the two, the Berlin is the less important, as being relatively of a temporary character, but it says much for the energy of our German friends that two such large exhibitions should be held at the same time, more especially as the two cities are relatively not far apart, and are connected by a direct line of railway. It is no fault of the Hamburg authorities if their exhibition is not well known among horticulturists. For months past a flood of programmes and notices of various kinds have been poured on us, and we could not take up a horticultural journal, whether in this country or on the Continent, without seeing the device adopted by the authorities, viz., a little plant about to be lifted by the spade.

THE HAMBURG EXHIBITION has so far achieved complete success, owing to the enthusiasm of the Hamburg people, the excellence of its management, the funds at the disposal of the committee, the distinguished patronage, and last, but not least, its good general organisation. Among the principal members of the committee are Dr. RUDOLF HERTZ, Dr. KLEBAN, Dr. ZACHARIAS, and other indefatigable and zealous organisers. Upon Mr. J. AGENS has devolved the formation of the design and the carrying out of the entire work.

All sections of the exhibition—permanent, horticultural, and industrial competitions, the formation and laying out of the park, the arrangement of the plans of the buildings, the tent containing illustrations of various florae, the hall with representations of the public promenades in the chief European cities, the *salles de fêtes*, the electric lighting of gardens and buildings, the decorations and superintendence, in fact, the entire organisation of an enterprise which will for five months be the pleasure and pride of Hamburg, and make its mark in horticultural annals, is under the supervision of "Burgomaster Dr. J. G. Mosckenberg, Magistricus."

The spring show was opened with due ceremony by the Burgomaster on May 1 in the presence of many visitors. This temporary exhibition occupies the large hall of the principal building, which measures nearly 8,000 square metres (1½ acres), various rooms and galleries, all connected one with the other for a length of nearly 2,000 feet. All these rooms are lined with plants. The principal building, planned in the German style, with a large central nave, supported by massive columns, with galleries, corners with low and semicircular platforms, is turned into one large garden of great beauty. A lawn, with a pretty lake and cascade, whence the water passes under a viaduct supporting a group of statory; a passage leading to the park, large chandeliers of incandescent lamps, and various other decorative features form the background of a picture whose foreground is constituted by glorious groups of magnificent plants. At the end of the hall a sloping bed, occupying the entire width of the nave, is planted with Indian Azaleas, hardy Azaleas, and Rhododendrons, and edged with hundreds of Lilies of the Valley.

Behind these, at the base of tall Palms, is a wealth of flowering plants, principally Clivias; on each side is a pyramid of blooming *Horrensias*, whence spring splendid Tree Ferns with fine effect. On each side of the large hall, before the two flights of steps, is a magnificent arrangement of hundreds of ornamental and flowering plants, beautifully disposed. At the entrance another fine bed of Indian Azaleas is bordered with *Livistona rotundifolia*. In the four corners of the centre of the hall are groups of mixed plants, one group, composed principally of *Crotons* and *Pandanus*, attracting much attention from their excellent cultivation.

In the lawn round the lake and in other places, baskets of flowering and foliage plants, specimen Palms and *Araucarias* look well against the green turf.

The hall is well planned; the paths are very broad, though scarcely sufficiently so to permit, on the opening day, the number of visitors to move easily. All is, however, on a large scale, as is evident at a glance.

Among the innumerable exhibits which adorn the galleries and intersecting halls we must note, in this rapid general account, the interesting contribution of Orchids, among them those from Baron Schröder, which form one of the features of the present show; new and rare plants, splendid *Caladiums*, flowering *Bromeliads*, *Lilacs*, *Hortensias*, with splendid trusses; very fine *Amaryllis*, *Carnations*, *Hyacinths* and *Tulips*, *Primulas obconica* and *Sieboldi*, *Araucaria* and *Agave Bertolonii*, *Anthuriums*; these and many other treasures too numerous to mention.

The work outside is done in a bold and most effective manner, the grouping of the trees, shrubs, &c., being done separately, so as to display each family or distinct form of plant to the best possible advantage; thus, one part is a fine group of *Picea pungens* (the Blue Spruce), in others groups of different species, and again in others are groups of Golden Yews, &c.

Later on, the Roses, which are planted in large numbers, should prove to be a fine sight.

The President of the International Jury is M. AUG. SIEBERT, Gartenbau-Director, and Manager of the Palm-gardens at Frankfurt-on-the-Maine; M. WILHELM LAUCHE, Hofgarten-director to the Prince JOHANN VON UND ZU LICHTENSTEIN, is Secretary-general. Among the members gathered from nearly every country in Europe, we were pleased to notice many representatives of the horticultural Press, who may well feel gratification at their connection with so successful a horticultural exhibition. To give our readers some idea of the cost of the exhibition, it may be stated that the buildings and the groundwork, &c., involved an expenditure of no less a sum than 200,000 marks (£10,000). The enterprise exhibited by the executive is highly commendable.

The English section of the jury comprises Messrs. BALLANTINE, GORDON, HUDSON, and SANDER.

To Baron von SCHRODER (gr., Mr. BALLANTINE) is

awarded a Gold Medal, for his exhibit of Orchids; and to Messrs. SANDER & Co., St. Albans, a Gold Medal and special prize of 100 marks, for *Dracaena Godeffiana*, as the finest new plant and novelty in the exhibition. The plant in question is a remarkably fine example. Having been shown in England, any further description would be superfluous.

THE BERLIN EXHIBITION is held in commemoration of the seventy-fifth anniversary of the Society of a forbiddingly long name, which we may shorten to that of the Prussian Horticultural Society. It was opened a day or two before the Hamburg Exhibition, by the Empress of GERMANY, and is the most extensive show of the kind ever held in Berlin, the space enclosed being no less than 14,000 square metres, of which 10,000 are covered in.

The Roses occupy the greatest amount of space, but it is to be deplored that the dull cold weather in April proved so unfavourable to the forcing of Roses, so that numerous plants had only a few of their blossoms expanded.

Next to the Roses the Palms are the most numerous represented, and, most fortunately, some extensive collections containing many diverse and rare species, and a few large and beautiful examples.

Orchids are poorly represented, and are not so good as in 1890. Among foliage plants, the *Caladiums* in large collections are deserving of special mention; also the variegated *Crotons* (*Codiaeum*), which are now hardened-off in Germany in rather low temperatures, and in consequence they are available for employment in apartments without suffering.

The most remarkable display of flowering plants is made with a collection of the best varieties of *Rhododendrons*, arranged on a large rocky.

Of *Azalea indica*, the plants observed are small in point of size—1 foot in diameter in the case of the smallest; examples of from 2 to 3 feet in diameter being entirely missing. The collections of zonal *Pelargoniums* are very good; *Cyclamens* are shown in moderate numbers, but amongst them some specimens of the finest quality, carrying about 200 gigantic blooms (raiser, CARL EHRENT, at Zielenzig) were noted. The *Cyclamen* previously mentioned in these pages as being shown by H. TORBENTHAL are inferior to these plants.

The specimens of *Hydrangea hortensis*, with red and blue flowers, are numerous, likewise *Fuchsias*. Most remarkable are the Cape and New Holland plants, which are at length receiving attention. *Ericas* are shown in large collections; and *Boronias* are shown by Messrs. SPIELBERG & DE COENE, of Pankow, in excellent examples.

In accord with the taste of to-day, herbaceous plants are largely shown, inclusive of *Primulas* and *Auriculas*, and in particular those from H. BACKER, of Pankow, are excellent. A new feature at exhibitions are the "room plants," shown by persons who cultivate them without professional assistance; and especially numerous in such exhibits are species of aquatics and Cacti. Valuable and extensive collections of Cacti are displayed by various commercial cultivators.

Among hardly subjects Conifers are very fine, the best collection coming from H. LOBBERG, Berlin. Two small plans of gardens made and shown by students of the horticultural schools for girls at Friedenan are worthy of notice. These are intended to show the best manner in which an *Acre* (109 square metres) of land can be laid out and cultivated. The idea is to exhibit to the poorer class of Berlin in which way the many vacant building-plots in the vicinity of the metropolis awaiting the builder, but which can be rented provisionally, can be made to grow vegetables. And with the intention of showing at what cost, and with what profit this can be done, every expense, exclusive of rent, and the cost of labour, and all takings, are given.

In the technical section, a novelty is shown of a window-plant sill or board which prevents water dribbling on the pedestrian when the plants are afforded water. It was exhibited by H. HILDBRANDT, of Lankwitz, a place south of Berlin.

FIG. 104.—LOUVE CARPENTIER'S HORTICULTURAL SOCIETY'S STING-FLAYER SHOW, IN THE WATERBURY STREET, HINSDALE, APRIL 2, 3, AND 9, 1897.
(Showing the method of arrangement, which provides isolated groups and regular masses in the place of long lines of straight tables. See report in issue of 27 April 1897.)

ROYAL HORTICULTURAL SOCIETY.—The next fruit and floral meeting of the Royal Horticultural Society will be held on Tuesday, May 11, in the Drill Hall, James Street, Westminster, from 1 to 5 P.M. At 3 o'clock a lecture will be given by Mr. G. MASSEE, F.L.S., on "Diseases of Plants, especially of Orchids."

THE CRYSTAL PALACE FRUIT SHOW OF THE ROYAL HORTICULTURAL SOCIETY.—The subjoined letter explains itself:—"I feel inclined to head my letter 'Lost, Stolen, or Strayed, £100,' for though not 'lost,' or 'stolen,' the £100 required for the Autumn Show of British-grown Fruit certainly seems to have 'strayed' into the all-devouring capacity of the many-mouthed Diamond Jubilee projects. You will remember that when the Autumn Fruit Show, which had been held from time immemorial at the Crystal Palace, had fallen through, the Royal Horticultural Society offered to revive it as a Show of British-grown Fruit, with prizes to the value of £250, on condition that those interested in the encouragement of fruit-growing in this country would subscribe not less than £100 towards the unavoidable expenses. For the last few years this £100 has been forthcoming, and magnificent shows have resulted, teaching thousands and thousands of spectators what fine fruit can be grown in Great Britain, and instructing very many planters as to the best varieties with which to stock their orchards and gardens. Alas, sir! this year of special grace, the £100 has strayed—it is not—or, at least, is not as yet. Letter after letter reaches me to the effect, 'Very sorry, but am so bedeviled with Jubilee projects, that I cannot help this year.' In fact, Peter is to be robbed in order to pay Paul. May I be allowed to appeal to all interested in British fruit not to let our great annual show fall through for lack of £100. Immediate help is wanted, as the schedule is all ready for issue—all ready with this one all-important exception. W. Walks, Sec., R.H.S., Vicar of Shireby, Croydon.

HAMBURG GENERAL HORTICULTURAL EXHIBITION.—The following gentlemen have been selected by the French Minister of Foreign Affairs as delegates of France at this exhibition:—M. Viger, formerly Minister of Agriculture, and successor to the late M. Léon Say in the office of President of the Horticultural Society of France; M. Chateaux, general Secretary of the same society; M. Nanot, Director of the School of Horticulture, Versailles; and MM. Truffaut and Martinet.

FANCY PANSIES.—We have received from Mr. H. KEMPSHALL, Lampport Hall Gardens, Northampton, some very beautiful Pansy blossoms. The strain from which the seed has been procured is proved a good one by the size of the blooms, many of them being upwards of 3 inches across either way. The colours are fine also, and the plants have evidently been skilfully cultivated.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting, in usual course, will be held on Monday, May 10, 1897, when a discussion will take place on the paper read by Mr. J. H. REDMAN (Associate), at the last meeting, entitled, "Some Legal Incidents of Tenancies of Urban Property, as illustrated by Recent Decisions."

ANEMONES.—Mr. HARTLAND sends us from Cork a box of very fine Anemones of the S. Bridget strain. In spite of being tramped, worn, they revived in water, and presented a striking appearance.

FEVER IN PLANTS.—Mr. H. M. RICHARDS, who has previously studied the effect of wounds on plant-respiration, now describes (*Annals of Botany*, xi., 29) a course of experiments on the evolution of heat by wounded plants. He finds that accompanying the increased rate of respiration is an increase in the temperature of the parts affected. A kind of fever supervenes, and as in the case of respiration, the disturbance runs a definite course, and attains its maximum some twenty-four hours after injury. It is interesting to note that the attempt to rally from

so injury is accompanied by somewhat the same symptoms, increased rate of respiration and evolution of heat, in plants as in animals. Owing to the nature of the case the reaction is less obvious in the former than in the latter, and a delicate thermo-electric element was required to appreciate the rise in temperature; but compared with the ordinary temperature of plants in relation to the surrounding medium, the rise after injury is "as great, if not greater than in animals." The maximum in all the plants investigated was between two and three times the ordinary excess above the surrounding air. Potatoes proved the most satisfactory objects for experiment, and it was found that in massive tissues (such as Potatoes or Radishes) the effect of injury was local, whereas in the case of leaves (e.g., Onion-bulbs) a much greater extent of tissue was sympathetically affected. *Natural Science*.

ABIES BRACTEATA.—We are indebted to the Earl of Dufferin for the following measurements of this tree, which was planted at Tortworth probably between 1858 and 1862:—Height, 52 feet; circumference at 1 foot from the ground, 6 feet; spread of branches, 36 feet. The soil is old red sandstone, the aspect much exposed to S.W. winds, and about 260 feet above the sea. Male catkins of this tree and of *Picea sitchensis* were also obligingly forwarded by his lordship.

A JUBILEE WALL DECORATION.—The loyalty of the British public is this season to find expression even on such articles as wall decorations. Messrs. ALFRED CHAPMAN & Co., of Rathbone Place, W., have brought out a specially-designed frieze and filling to commemorate the present year of Jubilee. The wall-filling shows a design of Roses, Thistles, and Shamrocks, and part of the frieze is in accordance with this, but is intended to be a setting for one or more "picture" panels. These panels represent the QUEEN overlooking troops of dancing children bringing offerings typical of various British and Colonial arts and sciences. Wall-filling and friezes can be had in green or in terra-cotta shades, and seem especially well adapted for use in public rooms or other buildings in which Jubilee business may this year be transacted. The firm above mentioned have also ready some transparencies and window decorations useful to those who wish to illuminate.

"CULTURE DES CHRYSANTHEMES A LA GRANDE FLEUR ET A TAILLE BASSE." By G. CHABANNE and A. CHOLET (LYONS: JUVORE ET FILS).—We have just received a copy of this cultural manual, dealing with the production of dwarf large-flowered Chrysanthemums, or, as the authors call their method, "culture Lyonnaise." The work was first issued about a year ago, but it appears that a second edition has been called for, and although the contents are in many respects similar, the new issue is revised and enlarged, and contains several fresh illustrations. Besides the ordinary cultural directions in the body of the book, there is a calendar, and a list of varieties.

THE TOTLEY HALL DAFFODILS, owing to the kindness of their owner, Mr. MILNER, are becoming very well known to such Yorkshire folk who admire a floral display. The gardens have recently been again thrown open to the public, when about 500 persons visited them. Daffodils are treated as a *specialité* at this seat near Sheffield, and the collection includes such rare and valuable varieties as *Glory of Leiden* and *Weardale Perfection*. Mr. T. BIRKENSBAW has charge of the gardens.

"ENCYCLOPÆDIA OF HORTICULTURE."—The MACMILLAN COMPANY announces that the compilation of an *Encyclopedia of American Horticulture* has been begun under the editorial supervision of Prof. L. H. BAILEY, of the Cornell University. There has never been a really good and adequate presentation of American horticulture, and this book proposes to make good the want. It is to cover horticulture in its widest sense, pomology, floriculture, vegetable gardening, greenhouse matters, ornamental gardening, the botany of cultivated plants, and the like.

The work will consist of signed articles by specialists, profusely illustrated by engravings made expressly for it. The articles will be arranged alphabetically, and it is expected that the number of entries will be about 6000, comprised in three large volumes, dated 1900. The earnest co-operation of every student of horticultural pursuits, and every lover of rural life is solicited, in order that the work may be worthy of the opening of the twentieth century. *Botanical Gazette, March*.

PHORMIUM COLENSOL.—In regard to the comparative hardness of this plant, and its propagation by means of seed, we have received the following interesting note from Mr. A. PETERREW, the well-known gardener at Cardiff Castle:—"This fine ornamental plant stands well planted out in the open shrubberies here, and is seldom injured by frost in the severest winters. It has on several occasions, during the last sixteen years, flowered freely, and produced abundance of well-ripened seeds, which, when sown, germinate freely; but, strange to say, I have not succeeded in saving any of the plants. I have tried to raise them from seed for several years, but utterly failed to produce a plant which had chlorophyll in its leaves. The leaves are white, and the plants seem strong, but when they have grown to about an inch in height, they dwindle off and die."

WIREWORM AND PROTECTIVE PLANTS.—On reading a note in a contemporary on "Capture-plants" being cultivated in some German gardens to clear the land of eelworms, we are reminded of that which was not an uncommon practice many years ago here, in regard to quite as dreaded an insect foe, the true wireworm. So greatly infested was the soil in some gardens as to make it an impossibility to grow roots of Carrots fit to put on the table, or to raise sufficient Parsley to meet the demands of the kitchen, unless rows of Lettuce were sown alternately with the plant it is desired to protect. The wireworm is evidently a creature of very decided predilection as regards the food it imbibes, and although passionately partial to the juices of Carrots and Parsley, it deserts them both to feed on Lettuce. Another instance of the protection that one kind of plants affords another occurs in the case of the mole-cricket, *Gryllotalpa vulgaris*, a voracious feeder on the roots of plants; an *Lata* some savor on worms, larvæ, &c., which prefers a Potato-tuber to anything else, but abominates the roots of the Cucumber, although it will burrow in the loose, rich soil of Cucumber frames in search of food, committing plenty of havoc in doing so. Hence, in countries where the mole-cricket is more common than it is in Great Britain, it is a general practice of gardeners to set Potato-tubers just beneath the soil as food for them.

BEECH.—Dr. FRIDRICH KRASSER has recently published, in the *Annalen des K. K. Naturhistorischen Hof Museums*, Vienna, a monographic sketch of the genus *Fagus* and its allies. Four species of Beech proper are retained, viz.: 1, *sylvatica*; 2, *Sieboldii*; 3, *japonica*; 4, *ferruginea*, Aiton (= *F. Americana* Sweet). The other Beeches, sixteen in number, are included in the genus *Nothofagus*, characterized by short styles; male perianth cup-shaped, irregularly lobed; stamens thirty to forty; scales of the involucre free.

LONGEVITY OF THE LARCH.—The *Chronique Agricole du Canton de Vaud* contains various records concerning the age attained in Switzerland by the Larch. There are at Maysens-le-Sion two old Larches which measure from 29 to 22 feet round the base, and 65 feet in height. Both are referred to in a plan of the grounds dated 1546, where they are mentioned as "the two Larches before the house." They were then a good age; and now are 351 years older. These years do not seem to have weakened them, as they are in full vigour. Another Larch is found on the Alp de Torrent, near Albinen; it is called the boundary-tree, as every hundred years the people of Albinen and Louèche-Bains go out to it to re-mark the boundary. On its trunk a sort of niche has been cut in the bark, and on the exposed wood are engraven the dates

from 1400 to 1700. Larch wood has considerable durability; the above journal mentions a chilet at Loucheles-Bains where the piece of wood which supports the ceiling is of Larch, and bears the date 1536.

AN APPLE-PEAR TREE.—M. TH. BIELER commented an interesting fact at the meeting of the Société Vaudoise des Sciences Naturelles, at Lausanne, on Nov. 4 last. He brought forward a fruit intermediate between the Pear and the Apple, a sort of "Apple-Pear," gathered in 1893 in an orchard in Canton Vand, on an espalier Apple, Belfordshire Foundling, several branches of which intercrossed with those of a neighbouring Pear-tree, Maréchal de la Cour. The fruit bore traces of both species; it had the eye of the Apple, and the stem was inserted in the oblique manner of the Pear. M. BIELER thinks that it is a case of impregnation, not of simple hybridisation, an example of "xenia," according to M. FOCKE's terminology. Xenia is very exceptional. It consists of a sort of cross-breeding, evident in the seed and in the fruit, although, usually, the fecundation of a flower by pollen from a different species results in a seed having the characteristics of the seed of the mother-plant, while the plant growing from such seed has the characteristics of the male parent. M. BIELER observes that if there be already examples of a Pear-Apple, an Apple-Pear is not yet known. Further, he does not guarantee the certainty of the phenomenon in the present instance; since 1893 no Apple-Pear has been produced, but the thing is possible, and in 1893, the similarity of the blossoms of the two trees was noticed. This is rare, as the Pear usually blooms before the Apple.

MAIZE AND TEOSINTHE.—In the American Museum of Natural History, New York City, there is an ear of corn displayed in the room on the ground-floor at the left-hand side of the main entrance, which was collected by CARL LEMMOLZ, the explorer, among the Tarahumara Indians of Mexico. It is identical in all respects with the form which I described in *Garden and Forest* (vol. ix., p. 522), as produced by crossing, for three seasons successively, Teosinthe (*Echinochloa luxurians*) and Maize. It is interesting to note the occurrence of this form among a wild tribe which comes little in contact with white men. Dr. NICOLAS LEON, of Mexico, informs me that this hybrid is encountered among the Mixes and the Zapotecs inhabiting the State of Oaxaca, and that there it is called Maíz de los Gentiles. Another interesting fact concerning Maize and Teosinthe is one made known by Dr. WILLIAM TRELEASE, of the Missouri Botanical Garden. It is well known that corn-stalk, *Ustilago Zea-Mays*, fastidiously confines itself to the Maize-plant, being found on no other plant. Dr. TRELEASE discovered that it also grows parasitically on Teosinthe, a fact which also points to the close affinity of Maize and Teosinthe, if they are not identical. J. W. HARTSBERGER, in "*Garden and Forest*,"

INSECT POLICE.—We take the following extract from an article of Mr. R. C. PERKINS, published in a recent number of *Nature*, p. 499:—"The first importation of Coccinellidae to destroy hordes of scale-insect in the Hawaiian Islands was made in 1890, when *Vedalia cardinalis* Muls., a native of Australia, was sent over by Mr. ALBERT KOEBELE. At that time many trees were in a deplorable condition from the attacks of *Icerya*, Monkey-pod trees being particularly badly infested—so much so that they were being largely cut down as the only recourse. The *Vedalia* was a complete success; it became perfectly naturalised, increased prodigiously for a time, practically cleared the trees, and then, as the *Icerya* became comparatively scarce, decreased in numbers, while at the present time it is evident that the number of the scale and its destroyer has arrived at a fixed proportion. Previously to its introduction here the same lady-bird had done excellent service in the fruit orchards of Lower California. . . . In many parts of the islands the Bananas and Palm-trees have been severely attacked by the larva of a species of *Pyralidina*. There is little doubt that in course of time this plague will be entirely kept under by a fine *Chalcid* (Chalcid

obscurata, Walk.), introduced from China and Japan, which has already multiplied enormously at the expense of these caterpillars—so much so, indeed, that in many localities the trees have now entirely recovered. Again, within the last few years a *Lamellicora* beetle (*Adoretus nimbrosus*) has been introduced from Japan. This insect speedily multiplied prodigiously, and soon destroyed nearly every Rose-tree in Honolulu, and subsequently attacked the foliage of many other trees. The cultivation of Roses—once a feature of the city—became impossible, while a remedy seemed hopeless. One day, however, Mr. KOEBELE discovered a parasitic fungus, and by cultivation of this, and infecting healthy beetles, soon spread it far and wide. Whether the fungus will prove entirely effective is not at present certain, but in any case it will be a most useful aid. The writer has seen the ground under trees which were attacked literally strewn with dead beetles—all killed by the fungus—and beneath the surface of the soil the larvae had likewise perished. It is at least certain, therefore, that myriads of the beetles were destroyed very shortly after the fungus was spread around by the individuals that had been infected."

PUBLICATIONS RECEIVED.—*The Genealogical Magazine*, a Journal of Family History, Heraldry, and Pedigrees (ELLIOT STROCK, Paternoster Row). This is the first number of a well got-up magazine, which we commend to the notice of genealogists and antiquarians.—*English Illustrated Magazine*. The May number includes, among other interesting contents, an article upon the various homes in which Queen VICTORIA lived in her youth.—*European Mail*, a useful periodical for absent friends.—*Expanded Metal and its Uses in Fireproof Constructions*, published by the Expanded Metal Co., Ltd., 39, Upper Thames Street, London, E.C.

HOW TO DIS-ESTABLISH BRACKEN.

I ENVY your correspondents who cannot get the common Bracken to grow in their woods. Here,abouts, the difficulty is to prevent it getting the upper hand. Mr. Fish's rough and ready plan of "clothing the landscape and woods" with it is the best, where transplanting is adopted, but by seed is the easiest. Transplanted about this season, the wounded rhizomes bleed and die, or become so weakened that they do not soon recover, and that, probably, is one reason why transplanting sometimes fails; but dug up as soon as the fronds turn brown, it will grow like a weed. I, however, caution owners against introducing Bracken into their woods, because it is a fertile cause of fires, and very injurious to the underwood and young trees. Old workmen in the woods here have assured me that they remember the time when some of our most extensive woods were comparatively free from Bracken, and full of underwood that was readily sold with the timber that was felled; but in these woods at the present day the Bracken forms one unbroken mass from 4 to 6 feet high (I have found single fronds 12 feet long), and all the underwood (Hazel, &c.) is destroyed. Before the Bracken came, the underwood used to grow freely again from the stools; but wherever cut down after the Bracken had got dense, it never grew again, being smothered in the first and second years by the latter. In a wood of 60 acres, from which a good crop of underwood was sold in 1868, there is now not a stick, the Bracken having smothered it. It would be the same with young plantations were I not to employ squads of men and boys to beat down the Bracken at the stage when it bleeds freely when beaten; and this practice has to be continued till the trees get their tops above it, otherwise the tree-crop would be lost. This beating the Bracken down when the fronds are just unfolding and brittle certainly weakens, and finally kills it; but it is expensive work, and the cutting of Heather and other rough herbage is nothing to it. It is a veritable nightmare to anyone having the charge of woods where it

abounds. As to fires, we have one Oak wood of some 1400 acres on this estate, almost every acre of which has been swept severely by fires caused by railway locomotives during the past twelve years, and all owing to the dead Bracken, which, between January and June, gets as dry as tinder and fires as readily.

In every case sparks from the railway engines of fast trains have caused these fires, and a decision by the higher law courts on a claim for damage (by a nobleman whose name I forget) last year, has brought the frequency of, and responsibility for, such conflagrations into notice in some of your contemporaries. In the case of the wood here, the railway traverses the wood for about 4 miles, and on windy days the sparks from the engine are blown among the Bracken at the side of the line, and in a few minutes afterwards the wood is ablaze, a wall of fire rushing through it that nothing can resist, and it has to burn itself out. In one fire, a few years ago, the flames traversed a mile or more of wood in one direction in a broad belt, destroying, among other things, about 450 old and tall Hollies, which were burned to their topmost twigs. These were all valued separately. The damage to the Oak and other timber trees consisted in the scorching sustained by the trunks of the trees, killing many, and cankering all more or less, so that they had to be felled and sold. The history of the valuation of the damage caused by these fires would form a unique chapter in forestry. I am told by those who know, that we have quite beaten the record. The late Mr. Bruce Findlay, of the Manchester Botanic, acted for the railway people, and we always got on fairly. Until the railway company adopted my suggestion and beat down the Bracken within a certain distance of the railway these fires were all of almost annual occurrence, and many a wanderer in the Bracken I and Findlay had. I cannot forget his coming one hot day when the Bracken was waist-deep, and held you like a rope, his turning round and asking, "Is it all like this, Simpson?" and when I assured him cheerfully that the exceptions were worse, he sat down on the nearest stone, and his remarks on "Feras" need not be here repeated. I know I offered to supply him with any quantity of roots, "put on to rail" free of cost if he would dig them up, and when we got among the Blechnum, he took me at my word, and not a few of these used to or may now adorn the shady corners of his "Botanic."

If Bracken could be employed for any useful purpose, it would be different. There is a big paper-mill near one wood where Norway and German wood-pulp from Spruce is used in enormous quantities, but I cannot persuade them to take our Bracken. It will make paper, as they have proved, but it wants too much cleaning to get at the fibre. I have not, however, given up hope, as I find the stalks of the fronds, where the fibre is dead, can be almost shaken free of the leaf portion, and if these stalks could be collected at a reasonable rate, the above objection might have less force. Meanwhile, if you can tell me of any plan of getting rid of Bracken as easily as it can be transplanted, you will oblige.

Reverting to the subject of claims for damage to woods and farm crops caused by railway engines, I may say that in the law case referred to above, the claim was by a nobleman in the south of England for a large amount for damage to woods, and that he lost because the railway company pleaded successfully that all reasonable care had been taken, and the case is likely to afford a precedent for the future. The subject is important, because fires amongst crops are continually taking place near to railways. As these fires are almost all caused by fast trains (the speed of which has been increased) on windy days by the sparks being blown from the engine funnel, there is only one way of preventing the sparks reaching fields or woods, and that is by causing the sparks to fall on the track. This has been done, I am told, in America and also on the Highland railway, by a device for turning a spark-guard over the mouth of the funnel when required. I suggested this strongly to the head engineer of one well-known line, but his objection was that anything of that kind checked the draught and speed on gradients, and that on windy days, when

fires were most likely, the wind-pressure on the train caused the wheels to hit the rails more closely, and this, in its turn, had to be overcome by harder firing, which caused the sparks to fly. I leave it there, but I still think a wire guard above the funnel practicable.

If railway companies intend to plead non-liability it will be a hard case for some. I have naturally had a good deal of correspondence on the subject from parties whose crops have suffered. Woods, corn crops, Hay crops, and timber yards seem to be most liable to catch fire. I find the railway people are already acting on the recent judgment referred to

on dark nights, as I have special reason to know, the stream of sparks left behind the engine resemble the tail of a comet more than anything else, but fires never occur except when the wind is strong enough to blow the sparks off the rails where there is nothing to catch fire—a fact which suggests the means of prevention. On these windy days the railway company do take precautions by posting men along the line with branches in their hands to beat the fires out at the first ignition. If that is not done, the flames get beyond control in a few minutes, and all the fires mentioned have occurred in spite of these pre-

ANTHONY WATERER.

MANY of our readers will be pleased to see a likeness of this typical English nurseryman, whose loss we have recently had to deplore. The illustration here shows Mr. Waterer when in the prime of life, and it is not difficult to read in his countenance the straightforwardness and determination which characterised the man. For him a plant was good or bad for its purpose; if bad, its fate was elimination, sharp and sure. A sketch of Mr. Waterer's career was given in our columns at pp. 628, 757, vol. xx.

LOWTHER CASTLE.

LOWTHER CASTLE has an air of princely magnificence about it, and standing as it does in a well-wooded park of about 800 acres, with the River Lowther running through the grounds, the approach to the mansion is picturesque and beautiful. The Earl of Lonsdale is the present head of the ancient family of Lowther, which has figured in history for at least 500 years.

"Nature and art to adorn the scene combine,
And flowers exotic grace this northern clime."

I was reminded of these lines after walking past the mansion and peeping for a few minutes into the sculpture gallery. Passing through the conservatory at the west end of the mansion, we came upon a natural dell, the sloping sides of which have been turfed and planted with choice shrubs—a fit setting for the beautiful geometrical garden laid out in the centre. Here Mr. Clarke has shown for several seasons how well the tuberous Begonia is adapted for bedding purposes. There are handsome vases studded about the garden in suitable positions. The sloping sides of the dell and the surrounding woods help to break the force of the high winds prevalent in the district.

This lovely spot is termed the Countess's Garden, and during last summer we lingered here to admire the effect of well-placed flowers and shrubs. The visitor next passes through into the Yew Avenue, composed of trees of immense size and great age, the stems curiously fluted in a twisted manner. They are so closely planted, that the branches are all intertwined overhead, and form a delightful shade in summer. There are also, outside the avenue, splendid examples of the never species of Conifers.

Some eighteen or twenty years ago, the *Gardeners' Chronicle* gave an account of Lowther and the dimensions of some of these notable Coniferae. At that time *Abies Douglasii* was 75 feet in height and 6½ feet in circumference 3 feet from the ground. Mr. Clarke very kindly measured this and other trees, and found it to be now 100 feet in height, and at 4 feet from the ground it is now 9 feet in circumference. *Abies Menziesii* was 65 feet high, and the girth at 3 feet from the ground was 5 feet. It is now 90 feet high, and at 4 feet from the ground the girth is 5 feet 7 inches.

Abies cephalonica was 50 feet high, and at a yard from the surface of the ground its girth was 4 feet; now it is 70 feet high, and at 4 feet from the ground, its girth is 6 feet 10 inches. When the report above referred to was given, a fine *Abies Pinsapo* was 40 feet high, but it was unfortunately blown down by a gale of wind in December, 1895. *Tsuga canadensis* was 42 feet in height, and 3 feet in girth; it is now 50 feet high, and 5 feet 4 inches in girth. There are two immense Ash trees, designated Adam and Eve, but Adam is the larger of the two. It was 21 feet in girth, 5 feet from the ground; it is now 23 feet. We leave the shady avenue of Yew trees, taking a lingering look at the noble Conifers, and are soon in the midst of a delightful Rose-garden—and such a garden; it is 3½ acres in extent, and contains upwards of 500 beds of Roses. Most of the beds contain but one variety, and all the best varieties of Roses are here. The Crimson Rambler is trained to poles, and in this way is very effective. The old Rose *Vivida* is grown as a pyramid, and Madame Plantier was well to the front. Lord Penzance's Sweet Briars are also planted freely. When I add that the beds are cut out of beautifully verdant turf, esme

THE LATE ANTHONY WATERER.

above. Quite lately, the owner of a small wood told me that he had planted it up, and had it turned either two or three times. On the last occasion, the company did their best to keep the fire within bounds with their own men, but declined to pay for the trees killed. He has now planted it again, and warned the company that they will be held responsible in future for such frequently-repeated destruction. The question is where does the "due care" and preventive obligations of the railway companies end? Our wood here is traversed by the fastest trains in the world (between London and Liverpool), according to an article in the *Stroud Magazine*. The incline begins at the one end of the wood; there the stoker begins to poke his fire up, and

cautions. Those who only know the common "Brake" in its dwarfed habit, as found on poor soils or exposed situations—as, for example, on the bleak coast of the Isle of Man, where it is about 6 inches high—may wonder at its rakness here, where it takes a man over the head, forming, when the fronds fade, one of the most inflammable masses possible. About thirty years ago a fire, supposed to be caused by a spark from some one's pipe, consumed 40 acres of wood. This was all replanted, and a few years ago this young plantation, which contained thousands of fine Corsican and Austrian Firs, was swept out of existence by a railway fire, the Bracken setting the green trees in one sheet of flame in a few minutes. *J. Simpson, Wortley.*

idea may be formed of the charming effect it has, but beyond this it owes much to the surrounding trees and shrubs. Carnations—"the fairest flower of garden"—are well grown here. The Carnation seems to succeed better out-of-doors in the North of England than in the South. The cooler, moister atmosphere, and probably greater rainfall, is apparently enjoyed by the plants. I have noticed particularly the vigour of the Carnations in the Thames valley. The rainfall at Lowther is about 40 inches each year. Under glass, Mr. Clarke had fine plants of the Tree-Carnations *Mlle. Thérèse Franco*, *Miss Joliffe*, and *Winter Cheer*. Some of the more notable growers of winter-flowering Carnations inform me that they have discarded *Miss Joliffe* for *Mlle. Thérèse Franco*; the latter has much larger flowers of the same delicate pink tint. Some of the old fashioned New Holland plants still find a congenial home at Lowther. The *Swainsonias* are fine, especially *S. alba*; it is a handsome sub-climbing plant. The *Gardenias* are grown well, and as *Gardenias* always ought to be grown, namely, planted out in peat and loam. Besides the old, well-known *G. florida*, the varieties *G. intermedia* and *Fortunei* are cultivated.

Mr. Clarke grows very excellent fruit in the houses under his care, and Cucumbers also. The best Peaches are *Stirling Castle*, *Cromson Galande*, and *Royal George*; these are forced early. In the late-house are *Barrington*, *Noblesse*, and *Princess of Wales Peaches*, and the *Stanwick Elruge Nectarine*. There are many objects of interest at Lowther, and few places in the North are so well worth a visit. *J. Douglas.*

HOME CORRESPONDENCE.

RHODODENDRON CAMPYLOCARPUM IN ARGYLLSHIRE.—I send a truss of *Rhododendron campylocarpum*. It may be of interest to many of the *Gardeners' Chronicle* readers to know that the bush from which this truss is cut was planted out-of-doors twenty years ago at Pottaloch in the West of Argyllshire. The plant is healthy, and flowers regularly every year, although not profusely. *D. S. McNeill, Pottaloch.* [See fig in *Gardeners' Chronicle*, 1892, ii., p. 699. Ed.]

VIOLETS.—"I am much interested in all that concern the varieties of this family, and I naturally perused with pleasure the article from Mr. D. T. Fish in the last issue of the *Gardeners' Chronicle*. I observe he mentions a white Neapolitan, and that its history is somewhat obscure. I have never heard of one of this description, except occasionally, and then of the habit and growth of *Swanley White*, which is supposed to be a somewhat delicate variety, and by some thought to be a sport from the well-known mauve-coloured Neapolitan. Assuming that I am right respecting its origin, although its reference is rather ambiguous, and that its history is apparently obscure, allow me to say "No; it is nothing of the kind." I purchased the stock direct from Conte Brazza in Italy, consequently, I had a just right to give it what name I thought proper. I also obtained a dark-coloured variety, and named it Venice, but it proved to be of no value. The name *Swanley White* was suggested by Mr. E. Bland, of Fuchsia fame, who saw and admired the first few flowers produced in this country—from here it was sent out, and ultimately certificated; and from the fact of its being such an acquisition, and probably not liking its proper name, the name Conte Brazza was erroneously used, and the variety advertised as being much better in several respects than *Swanley White*, but which time has proved to be fallacies. Strange to say, although I protested, editors have to this day thought it correct to allow its false name to be used. It has also been publicly stated by gardeners, who have grown the supposed two distinct varieties side by side, that they were identical. As a further proof, I supplied it in large quantities to expert growers in America, where it is to this day highly appreciated, and, I am grateful to say, always honourably called by its correct name, *Swanley White*. I hope after this explanation its fictitious name will no longer be used. Mr. Fish asks what distinction is there between De Parme, Lady H. Campbell, Marie Louise, and New York? These are all of the same colour, or practically so, and to a casual observer would be thought to be one and the same; but if the four were planted out, and allowed to stand all the winter in the open, it would be seen that

they differ in growth and in hardiness. Duchess of Edinburgh and Marguerite de Savoie might also be classed as similar, but they can well be dispensed with. Marie Louise is decidedly the best, although Lady H. Campbell is late, and flowers splendidly when the others are almost over. *Henry Cannell, Swanley.*"

—I have been interested reading in your paper the opinions that have been expressed about Violets, and in particular I noted what was written about the variety *Princess of Wales*, some of which I am able to confirm. I may say that this variety has had my close attention for at least fifteen months, and compared with about a dozen other varieties I am of opinion it is by far the best. It is very hardy, of free growth, a profuse bloomer, the blossom rich in colour and large, the flower-stalk long, and very fragrant. I can also bear testimony that up to the present I have not seen a diseased plant in beds containing a few thousand plants. I have grown *Violet Wellisiana*, *V. odoratissima*, *V. The Czar*, *V. Victoria Regina*, the *Russian Violet*, and others (in singles), for a long time. Each of these has its good feature, but none anything like so favourable as the *Princess*. *Amiral Avellan* (new) I have tried to a certain extent, and like its colour and habit. *Violet California* does not appear to be at home at present in our soil, except in a frame. If its hardiness does not improve, I am afraid I cannot speak of it succeeding in this locality. *Fred. Perkins, Northampton.*

ALLOTMENT GARDENS AT HIGH WYCOMBE.—Notwithstanding the fact that Lord Carrington has disposed of Wycombe Abbey and a portion of the surrounding land, a considerable part of the estate remains in his lordship's possession, and also the numerous allotment gardens for which High Wycombe is famous. At the present time there are 1200 allotments averaging in size from 16 to 20 poles, and all these are in the parish of High Wycombe. The price paid by the tenants is an annual one of from 5d. to 4½d. a pole, according to the position of the allotment and the quality of the soil. A memorandum of agreement between Lord Carrington and the tenant is duly signed, the tenant agreeing to properly cultivate the ground, keep it clean, free from weeds, well manured, and in good heart and condition. If the tenant erects a pigsty or any other building, he is at liberty to remove it at the end of his tenancy, or he may sell it to the succeeding tenant; but Lord Carrington does not undertake to take over the same by valuation. His lordship claims under this agreement to take possession of any piece of ground let as allotments on giving three calendar months' notice; and in case of such determination of the tenancy, the landlord pays for the cultivation or crops on the ground such a sum as may be agreed on, or as the same shall be adjudged to be worth by any valuer the said landlord and tenant may appoint, all rent due and half the charges of the valuer being deducted from the valuation. Rents are paid annually at Michaelmas, and Lord Carrington makes a point of returning 1s. to every holder who pays promptly. His lordship maintains all the boundary fences enclosing a piece of ground set out in allotments, and he pays all rates upon the ground; if the holder of an allotment desires to fence in his plot from his neighbours, he must do so at his own expense. The allotments are occupied by labourers and artisans chiefly, and some by tradesmen. Occasionally rent is unpaid, but cases of such are few. No action is taken by Lord Carrington as to the way in which the allotment is tilled; some are much better kept than others, which is usually the case. It is, perhaps, to be regretted that in parts of the country all allotments are too frequently allowed to lie untouched during the late autumn and winter months, when they become covered with weeds. Lord Carrington allows tenant-right in the case of an allotment being yielded up to another tenant; but, as a matter of course, an agreement with his lordship has to be signed, as no tenant can underlet or part with the possession of the ground or any part thereof. Lord Carrington will have allotments on all his estates; and in the case of High Wycombe, if a piece of land used as allotments lying near the town is required for a building site, a corresponding piece is set apart for allotments elsewhere. It will interest many friends of Mr. G. T. Mills to know, that in addition to having had charge of the gardens at Wycombe Abbey for the space of forty years, he has also taken the superintendence of the allotments during that time, and has had the satisfaction of seeing them greatly grow in number, conferring substantial benefits upon the community. *R. D.*

THE RENAISSANCE OF THE HOLLYHOCK.—I am glad to note that "D. L. M." heartily welcomes the Hollyhock back to the mixed border, of which its colour and stature were so long the grandeur and glory. But would successful growers had need be careful in following his advice, lest instead of a renaissance of the Hollyhock, they have a revival of the Puccinia, and the last estate of the Hollyhock-disease prove worse than the first. There is no objection to begin with the best possible seeds of the finest strains. But why, if stocks are really clear of disease, and one, two, or more true to name can be had from the grower already named, the days of budding, striking from cuttings, and grafting Hollyhocks are past and gone, is by no means obvious. As a matter of fact, all these processes are in full operation to the production of thousands of named Hollyhocks. Such modes of propagation were only laid aside while the Puccinia *malvaecorum* ruled, and reigned, and wrecked our Hollyhocks. But now that colonies of clean and vigorous Hollyhocks are raising their heads in various directions, the best strains are being perpetuated and multiplied on the only absolutely sure and possible lines. It is also found that the finest strains of Hollyhocks under cool treatment and careful quarantine resist the fungoid pests as well or better than seedlings. "D. L. M." may or may not be right in writing the best time to sow Hollyhock seeds is in the second week of March, but he is emphatically wrong in adding the seed-pot being put into heat; and the pottings first set into 60's, and then into 18's, and successive hardening off in time to plant in the open in May are all superfluous, and consequently worse than useless. The time is short, the processes are many, and the plants are necessarily hurried through by their vital and constitutional confinement. More likely processes for the conversion of the entire structure of the Hollyhock to a nucleus, for the nurture of the Puccinia pest can hardly be imagined. The raising in heat, the shift, the hardening off, the forcing, and the checks can do no possible good, and may do the plants irremediable mischief. Supposing "D. L. M." sowed his seeds in the open air in March or April, and left them severely alone, and kept them clear of weeds throughout the summer and autumn, the plants would assuredly be strong enough to place out to their blooming quarters in September or October. Or seeds may be sown in their forcing quarters at once. The Hollyhock is hardy if we do not coddle or cover it into tenderness. Cool open-air treatment from the first will relieve growers from the litter and labour of screens of Spruce Fir stuck round about and over their plants. Strong, sturdy, rather than rank growth is the secret of the perfect hardiness of Hollyhocks. I flowered about two thousand Hollyhocks a year before the wreck and ruin wrought suddenly by the Puccinia. And through all these years our weather losses were never heavy nor serious, and could be made good from our surplus stock of divided stools that were laid in by the heels, or planted out in the late autumn. I am glad to be able to agree with "D. L. M." as to the desirability of a frequent change of soil for Hollyhocks as often as practicable, and that the stations for the plants should be trenched and manured, and the plants receive good attention throughout the summer, affording water and manure when necessary. Also that seed should be sown annually to maintain a vigorous stock of plants, enough and to spare, to fully furnish the Hollyhock-quarters with the charms of novelty, as well as with the more stable and reliable, well-proved named varieties. *D. T. F.*

MODERN TREATMENT OF SPRING-FLOWERING BULBS.—Hosts of growers are at a loss at this season of the year, when their spring-flowering bulbs are past blooming, to know what to do with them. How to dispose of them, in fact, in the readiest manner—economically, and with regard to their safety and identification later on of kinds and varieties. Beds in which they have bloomed have to be dug up and planted with summer flowers, and this has to be done in a brief period of time, owing to the many calls on the gardener's time at this season. What seems to be the readiest way to overcome the difficulty is to chop out trenches upon vacant ground, place the different kinds of bulbs therein in their varieties, and stick to the end of each row a label with the name plainly written thereon. There is, however, danger when this plan is followed of the labels becoming displaced when the leaves have "died down," of their being mixed when dug up, to say nothing of decay during wet seasons—especially the latter when the soil in out-of-the-way corners is heavy. Now that varieties of Narcissi are

so numerous, and the bulbs ar, in many cases, valuable, the above make-shift plan does not seem very commendable. Mr. Jordan, the Superintendent of Regent's Park, has perfected a method, which for simplicity as regards nomenclature, &c., deserves to be known. The bulbs, when dug up, which is done early in the public parks, have their leaves cut off at about 1 inch from the top of the bulbs, they are then placed thickly in a layer in shallow boxes, and are covered over with light manure, or similar material, wherein they ripen off well and perfectly. Owing to the immense numbers grown, special arrangements have been made for the wioter storing, a shed capable of taking all the boxes having been specially erected, having numerous lightly-constructed eages to receive them. It is imagined bulbs in the parks are all purchased for planting each year; the real fact is, that great care is taken of those that have flowered. That Mr. Jordan's plan is a good one, needs no evidence of mine, when the fine quality of the floral display in this park in the spring is taken into consideration. *William Earley.*

CINERARIAS.—The efforts now being made with a view to determine the exact parentage of the garden Cineraria, and to develop new forms, will doubtless render the following extracts from the *Florist and Garden Miscellany* for 1849 both interesting and useful. Writing as a florist on "the properties of a good Cineraria," A. Kendall of Stoke Newington, a well-known and successful raiser of new varieties, says:—"The petals should be slightly cup; a perfectly flat flower will not pass, but if the petals refer to it is a fatal point, and cannot be overlooked." In an earlier part of the same article, the writer states that he "hopes yet to see every pip as large as a half crown, and as round as a full moon." In another part of the same volume appears a beautifully executed coloured-plate of the following varieties, Kendall's Princess Seeding, Sanspareil, Richard Cobden, and Henderson's Carlotta Grisi. Assuming that the natural size of the flowers is here shown, the best of them (Richard Cobden, a blue), barely attains the standard size. In each case the flowers lack substance, breadth of petal, and fulness of form. The illustration represents in every particular, except colour, a flower taken from one of the plants exhibited by James in 1896, the diameter being $\frac{3}{4}$ inches. It will thus be seen that Kendall's hopes have been more than realised; and, judging by the improvements effected during the past ten years, we may reasonably expect very shortly to see even better things. In the matter of colour, Kendall's dreams are to a certain extent unfulfilled, for while some beautiful shades of crimson and white are in existence, the scarlet and yellow that he considered possible have not yet appeared. Judged by the standard of points laid down in the foregoing extract, many of the largest flowers in our best collections would have to be condemned, as they are mostly reflexed. Happily the florist's code of points is no longer like the laws of the Medes and Persians, and one may fairly ask the question whether, in face of recent developments, it is not desirable to frame a new code? The Cineraria appears to be rising in popularity every year, both in Europe and America, and if our horticultural societies will do what is in their power to encourage and reward the men who have done their best to make the plant popular, our judges will soon need some such code to guide them in the discharge of their important duties. While the French and German growers have been working hard at the improvement of the Cineraria, it cannot honestly be charged to insular prejudice that the results of their efforts are not as highly appreciated in England as they doubtless are in their own countries. The flowers of the French strain, although very much larger than of our own, and in many respects embodying Kendall's ideal of form, are nevertheless much too loose, and also lack substance. On the other hand, the colours are generally very bright, and the appearance of the plant is very effective. If the German strain is fairly represented in the coloured plate recently issued by Mr. Benary, it may fairly be described as "large and singular." Only two flowers in the group at all approach the English standard, the others have two, and in some cases three rows of petals, each perfectly flat, and not in any way resembling the double varieties which are shown on other parts of the same plate. The range of colours is large and varied; but one very glaring defect is, that the colours of the centres are as varied as those of the petals, while our best English growers hold a dark centre to be a *sine qua non*. Judging by a display recently made at the Drill Hall, the double Cineraria is as susceptible of improvement as the

single form. At the same time they cannot be fairly described as a success from the commercial standpoint. Some of these days a startling development in colour will reward the patient and persistent grower, and then it is quite possible they may "catch on." *N. S. D.*

LIME-RUBBISH AND CANKER.—Very recently, when looking through a small orchard near Farnham, Surrey, and on rather stiff soil, I noticed some Cox's Orange Pippin trees, about ten years planted, that were in perfect health, making clean growth and carrying ample bloom. Yet on the main stems of the trees were evidence of canker having existed, in the form of big gaping wounds or eruptions. The owner of the orchard, an intelligent amateur, stated that when he saw the trees were becoming diseased, he had a dressing of well-broken mortar-rubbish lightly forked into the ground about the trees, and since then has given other occasional dressings, and to these he attributed the present fine healthy appearance of the trees. This matter is well worth knowing, because so many whose trees suffer from the canker-epidemic can try a similar experiment at trifling cost. Where mortar-rubbish is not at disposal, then fresh slacked lime strewn over the ground and forked in, may suffice, but there can be no doubt but that the silica found in mortar-rubbish is a useful element in the case, and particularly so in stiff soils. Such a fact as is here shown tells forcibly that canker is more the product of omission in the soil of a useful constituent than of any mere fungoid attack. *J. D.*

FRUIT TREES IN HEDGE-ROWS.—Mr. McDonald has pretty well summed up the merits and demerits of this matter, and his decision is certainly autogonistic. Practically, the country has nothing to gain by the growing of inferior fruit, such as would inevitably result from planting trees in hedge-rows. What with inferior fruit, and thin broken hedges that are really intended to become fences both against human beings and cattle, there would be loss in each case. The only form of fruit culture needed in this country is the very best. We have had too much bad culture, if the term "culture" can be rightly used, of inferior varieties in the past, with the result that we have nothing to be proud of. Were we so hard driven for ground to produce fruit that it was absolutely needful to plant trees in hedge-rows, we should have to make the best of the case; but it would be, indeed, a bad one. As it is, we have millions of acres of fine land delightfully situated and adapted for the purpose that may be most profitably utilised for fruit production provided it be on the best modern lines, and with the best varieties. To produce the fruit we so much need for the benefit of our home industry, as well as for our national reputation, we need the best of culture, fruit of as high quality as our fruit nurseries and best private gardens produce; but obtained not in bushels merely but by thousands of tons. Hedge-row culture will never give us that. Unfortunately, the needs of the case seem to be too imperfectly recognised. What immense results might be obtained ultimately would the Government but be as willing to sink a million of money in starting fruit culture as now in building ironclads or arming big battalions! *A. D.*

SCOTLAND.

APRICOTS UNDER GLASS.

The Apricot crop so often suffers from frost and cold weather that many owners of gardens have given up its cultivation where at one time good crops were common. The present has been one of the most untoward seasons for the setting of the bloom of the Apricot in Scotland of which we have any record. March was damp and cold, and at the end of the month there was severe frost almost every night, and April was not much better, the month being moist with northerly and easterly winds. When the bloom opened, it suffered severely, for no sort of protection seemed capable of warding off frost. In the midland and more northerly parts of Scotland they were generally much earlier than others many miles southward. In some parts of Perthshire the best Apricots are grown in Scotland. As, for instance, at Dupplin, where Mr. Browning has given them special attention for many years, and been well rewarded for his pains; at Kinlindsay Castle fine crops

have been gathered in common with other places in the district. Frost is generally severe in the places referred to, but the position of the gardens is elevated, and they are well sheltered from the north and east winds. The success attained at Dunkeld with wall fruits generally has often been chronicled, and we should like to learn what Mr. Fairgrievs' prospects are this season at that fine Highland seat. It is a matter for remark how little headway Apricot culture under glass makes in Scotland, very few gardeners attempting it under glass in Scotland compared with what one may meet with in many parts of England. It may be that the late spring frosts in the south, accompanied with the forcing power of the sun, renders the aid of orchard-houses more needful in the south. Still, where orchard-houses are well managed in Scotland (take Drumlanrig Castle as one of the best examples), they are very valuable adjuncts—in gardens; as quantity and quality far exceeds that of any culture in the open.

In England Apricots are often well done, the pots and tubs being taken outside and plunged in ashes after the crop is gathered where the wood is ripened; at which time the orchard-house is at liberty for other purposes. Some cultivate Apricots, with the roots planted in firm soil very successfully where the lights can be removed in the autumn, and the system of ventilation is in accordance with the requirements of the plants. This last is perhaps the chief point in the successful fruiting of the Apricot; and the quality of the soil has much influence in the production of fine fruits. I have before me a letter from Mr. McTaggart, the gardener at Arniston, Midlothian, in which he gives some details of his management of the Apricot. He referred to the splendid results obtained under glass last autumn which I saw in a simple lean-to house erected for other purposes, about 12 feet wide and over 12 feet high, with ventilation at the front 3 feet above the wall. Holes are formed for the emission of roots, and no doubt this is a good plan for fruit trees, as they will be induced to make plenty of fibre before they reach the open border. Mr. McTaggart writes that no special preparation was made for the Apricots beyond trenching the soil and mixing plenty of lime rubbish in it—this abundance of lime in the soil has much to do with the fine fruits and trees to be seen in Oxfordshire and Wiltshire on walls and buildings. The Apricots at Arniston carried a great crop, and the trees crop more or less heavily each year. The trees make short spur like growth, possess healthy foliage, and they are kept to a certain height (about half-way, or less), up the front near to the glass, which permits abundance of sunshine to reach the Plum and Peach trees trained on the back walls, which also bear fruit capably. Air is admitted abundantly, but never as cutting draughts. The garden at Arniston lies rather low on land that slopes towards the north. I think that the good natural soil, abundance of lime-rubbish, holes to allow of the egress of roots, and abundance of ventilation, have much to do with success in fruiting the Apricot at that place. *M. Temple, Carron, N.B.*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

APRIL 27.—Present Dr. M. T. Masters in the chair; Rev. W. Wilks, Rev. G. Henslow, Hon. Sec.

Tulips Discoloured.—With reference to the Tulips "Golden Crown" sent to the last meeting by Mr. Thomas Polegato, the following is the report received from Rev. J. C. The leaves are attacked by a fungus called Botrytis sulcicaria, a destructive parasite to various bulbous plants. The mycelium of the fungus travels down the tissues of the host plant, and forms minute sclerotia or lumps in the bulb and also in the soil in which the plant is growing. These sclerotia remain dormant during the winter, and commence to grow the following spring when the young leaves appear. Your correspondent is right in supposing that he will get no blooms. The wisest thing to do would be to remove all the diseased plants. It would not be wise to plant bulbs in the soil where the diseased plants have grown for the next two years. If this cannot conveniently be avoided, then let him plant "trap-

plants' that is, comparatively worthless bulbs—to take up the spores and sclerotia present in the soil, and then remove them early in the summer before more sclerotia or spores are formed."

Potissolan tuberosa.—Mr. E. POLLARD of Colwell, Great Malvern, sent a specimen of Swin having the yellow jelly-like outgrowth from the stem of this fungus. It is dimorphic, the second stage being *Potissolan costata cancellata*, and is found growing on decaying trees.

Pinus Torreyana.—Dr. Masters exchanged specimens of the large cones of this tree. It is found exclusively in a very small area on the southern coast of California, extending over about 3 to 4 miles only. It has since been discovered by Dr. Francischi on a hillside of Santa Rosa off the same coast. It is now in cultivation.

Lilacs.—Dorcas. Mr. Hoy of Brentford sent some Lilacs. Some grown on land newly manured with sewage matter and ashes, others on land which had not been manured for several years, having a very light soil. They were attacked with a species of *Peronospora*, allied to the Potato disease; so possibly a treatment similar to that for Potatoes might be advantageous.

Tulip with Anemone Flower.—Mr. TOMSELL, of Heaton, Newcastle-on-Tyne, sent a specimen of the Tulip *Prospere* in which an additional small flower sprang from the axil of a leaf on the scape. It is not a common production, but similar growths occur nearly all over.

Cucurbit Crosses.—MESSRS. JAMES & SON, of Farnham Royal, sent several nice growth plants, which they had raised (1) from seven *Cucurbita* garden forms, (2) from four plants (2, 3, 4, 5) resulting from the cross of (1) again crossed with *C. Heritiana* (6); also this last true species crossed with the first named (6). It had white flowers, with pink tips to the petals. Of the four plants, numbered 2, 3, 4, 5, No. 2 had foliage more resembling that of *C. Cucurbita*, but 3, 4, and 5 that of *C. Heritiana*, while three had a white ray and pink disk; 5 had both ray and disk of a crimson colour.

ROYAL GARDENERS' ORPHAN FUND.

APRIL 29.—The annual dinner took place at the Hotel Cecil, Thames Embankment, on Friday, Sir WHITTAKER ELLIS, Bt. in the chair, supported by numerous friends of, and subscribers to the Charity. Among the guests were N. N. Sherwood, Harry J. Veitch, Rev. W. Gould, Sheriff Rogers, Geo. Bunyard, Leonard Sutton, J. Wilks Vetch, J. H. Veitch, Arnold Moss, Geo. A. Dickson, P. Crowley, W. Sherwood McKenzie, R. G. R. Salmon, A. Tite, W. H. White, W. E. Carr, John Laing, J. Douglas, W. Marshall, A. Marshall, A. Taylor, E. Featherly, A. J. Moore, W. Bonpart, E. Taylor, Enoch White, W. J. Brewer, R. B. Gibson, A. P. Barrett-Todman, H. Harbst, G. Nicholson, K. Drost, Councilleur Turpin, Geo. May, H. B. May, E. Rochford, W. Leeton, D. B. Crane, H. J. Jones, H. J. Cutbush, Wheatley, A. Outram, B. Wrayne, T. W. Saunders, H. F. Woodson, P. Sterromann, G. Borne, Harry Williams, T. C. Ward, J. A. Lamb, J. H. Laing, W. Deering, G. Wythes, J. Ellis, Geo. A. Dickson, J. F. McLeod, R. Greenfield, E. Dean, G. Dean, W. H. Holmes, and A. F. Penny.

The toasts to the Queen and the Royal Family having been given, the Chairman gave the toast of the evening, that of The Royal Gardeners' Orphan Fund, which was received with several rounds of applause. He pointed out the great misfortune that awaits the widow of a gardener burdened with the care and maintenance of a family of small children, and showed that the best means of assisting the latter was by helping the mother, or some near relative of the family who would undertake the charge of the child. It was to the benefit of the children that the home be broken up, and that they continue to live together. It was the most natural arrangement, and the object of the Royal Gardeners' Orphan Fund was to enable the mother or the relatives to do this, or to place the children in suitable homes. And the question for the friends and supporters of the Fund was how to provide the means of doing this. Let every gardener do what lay in his power, let him lay the claims of the charity before his employer, and collect contributions from his friends. Nothing, said the chairman, delighted him better than to help the gardener. He could look back fifty-four years, although he was a great deal older, and could speak in favourable terms of his servants, and especially his gardener. The only difficulty he ever had with him was that he thought the gardener was his own, not Sir Whittaker's!

The chairman complied with the toast the name of Mr. Sherwood, who, in the course of his remarks, gave a brief recapitulation of the origin and history of the Fund from its commencement in the year 1825. He must, he said, congratulate the management on the success that had hitherto attended their efforts, for they had spent £9000, and had funded £10,400. This year the whole of the orphans whose case had been brought to their notice would be put on the Fund; and he alluded in this connection to the remarks of Mr. Owen Thomas, their present chairman, given at the *Gardeners' Chronicle*, February 27, p. 140. In spite of the good progress made, he was anxious to obtain new subscribers, and he appealed to the gardeners and their employers to assist.

Mr. G. A. Dickson, Chester, in moving the toast "Gard-

eners and Gardening," especially remarked on the extension of gardening in and about London from the artisans. In many parts of the country the best results were secured only by the unmitigated efforts of the gardener, who overcame the baleful influences of smoke and fog, the mineral character of climate and of soil.

The Rev. W. Willis responded to this toast in a humorous speech, of coarse character, but not without merit in the course of it. He did not believe that the gardener could contend for an eight hours' day, as his day began at 5 A.M. and ended perhaps at 10 P.M. He would like to point out to gardeners, and employers of gardeners, that the money that has been promised to various Jubilee undertakings was calculated to make the Fund a sufferer in the years to come, giving as an example the diversion of funds of which Dr. Barnardo has to complain, viz., £9000 a year. He hoped that the expenditure on entertainments, seats, &c. should not be allowed to interfere with benevolent efforts, and that whatever else it might not be the Royal Gardeners' Orphan Fund. Mr. Farrant proposed the toast of the chairman in the unavoidable absence of Sir James Whitehead, and Mr. J. Moss, that of the visitors.

We append the list of subscriptions:—Sir J. Whitehead £194 15s (including £100 Leonard Sutton, £52 12s, Sir J. W. Ellis, £10 10s, Sir James Whitehead £4, G. Reynolds, £25 10s, including Leopold de Rothschild £10 and Arthur Waterer £2); Ovent Garden Friends, per J. Aschew, £45 10s; Rothschilds, £26 7s, N. Sherwood, £28 2s; Baron Schroder, £24; A. W. G. Weeks, £20 8s; Alfred de Rothschild, £10; W. Low Eston, £10 4s; Dicksons, £10 10s; Harry J. Veitch, £10 10s; J. Veitch & Sons, £10 10s; Barr & Son, £10 10s; C. P. Crowley, £7 10s; W. Pompadour, £7 10s; W. G. Baker, £8 8s; W. J. Nutting, £7 15s; G. F. McKenney, £5 3s; K. Drost, £7 7s; J. F. McLeod, £7 5s; E. Gilbert, £5 10s; Geo. Bunyard, £5 5s; A. H. Snee, £5; A. W. Sutton, £5; W. Walker, £5; T. Williams, £5; £25 6s; P. Crowley, £5 3s; G. A. Dickson, £5 3s; B. Wrayne, £5 2s; C. P. Crowley, £5; H. Harbst, £5; S. M. Sagar, £5; W. H. Holmes, £5 2s; Geo. May, £4 15s; H. Eckford, £4 8s; W. Strutt, £4 3s; H. Balderson, £4 3s; J. Smith, £4 2s; P. Weinmann, £4 3s; Laing & Sons, £4 3s; W. L. Cory, £4 3s; H. J. Jones, £4 3s; B. Dean, £4 3s. Total, £2077.

THE HAMBURG HORTICULTURAL EXHIBITION.

MAY 1 to 30.—The first of the series of special horticultural exhibitions arranged to be held at Hamburg during this season opened on Saturday, May 1. Of these shows there are to be six, extending from the above date at intervals until September 30. The present exhibition is to be taken as a criterion of those that are to come, the executive may be congratulated on the success that will be attained. The present display is on a most imposing and extensive scale, nearly all of the planned available space being filled by the exhibits. These are distributed through several large, well-built structures. They are of considerable dimensions, and in the case of most of them, the arrangements are such as to provide the utmost protection for those plants which are of a tender character. These erections are sufficiently light for the plants to be seen to good advantage. The largest building, an immense one in every sense, is at that point of the grounds furthest from the chief entrance. To make a guess of the dimensions of this building would be hazardous. It stands on nearly two acres of ground, not counting the space gained by the many undulations. Viewed from the balcony at one end of the interior, the effect is magnificent.

GROERS.

In the distance the colour effect is decidedly fine and imposing, whilst, immediately beneath is a superb group of Indian *Azaleas*, which could not possibly be better arranged than they are on the opposite side. *Azaleas* have many varieties and the forms of *A. mollis*, till with great effect, as do the many examples of *Rhododendron* by which they are flanked. The *Azaleas* in this case are grouped as regards their colours, the central portion consisting of white varieties in the shape of a V reversed, the triangular space being occupied with small plants of a salmon-coloured variety; whilst, on either side of the white, purples and crimson tints with fine effect.

Further in the distance is an immense group of flowering and foliage plants; these, too, being arranged so as to give the best effect in the distance; in the centre of this group are to be seen numbers of *Civielis* with fine heads of bloom, and on either side groups of *Hydrangeas*, these all being arranged in a pyramidal form, each one being surmounted by immense specimens of Tree-Ferns and Palms, these being again backed up by the distance by smaller and smaller ones of the same kind. The effect of all this grouping on such an immense scale is grand in the extreme, such as we in England could scarcely hope to equi, and certainly not surpass. On either side are the largest groups of foliage and flowering plants; these, too, left most effectively in combination with groups of *Palms*, *Magnolias*, &c., of which there is an immense quantity.

Under the balcony are placed the largest examples of Sweet Bays, grand plants, some 10 to 12 feet in height, and clothed to the base. Through the centre the designs and arrangements are worked out on grass. These consist of

groups of *Cinerarias*, Oranges in fruit and flower, small *Azaleas*, *Tillandsias*, and kindred plants; *Anthuriums*, *Lilacs* of the Valley, small specimens of *Rhododendrons*, *Civielis*, &c., all of which tell most effectively. The presence of artificial rock-work upon a bold scale, with a strong force of water enacting in a stream in the centre, add to the effect. Upon some of the rock-work are arranged groups of *Adiantum mollis* and *Asplenium*.

Here and there are groups of *Pandanus Vetchii*, *Draena Lindenii*, *Crotus* in variety, and other telling plants of colour are associated, so as to enhance the effect as a whole. The green grass and broad walks give each in its own way an excellent finish to the whole.

The collection groups are carried out in other parts of the show, in most cases as designs on grass. One notable instance is the large erection with contains the greater portion of the forced or pot plants, as *Lilacs*, *Roses*, *Frunes*, &c., as well as *Anaryllus*, *Caradons*, and a fine mass of *Anthurium Scherzerianum* with extra large spathe. Through the entire exhibition there is no lack of Palms. In some instances these preponderate above everything else, yet the effect is excellent.

The permanent portion of the exhibition is not yet complete, and its completion will date from May 15, 1897. The exhibitors may be said to have succeeded in doing in fine effect anything that has been seen elsewhere. Here are to be seen by thousands plants of *Azalea mollis*, *Rhododendrons*, *Roses*, and other flowering plants well furnished with flower-buds, as well as an immense quantity of *Conifers*, *Palms*, and *Magnolias*, all arranged with care. *Abies*, *Piceas*, *Pinus*, *Arbor-vitae* (chiefly the American) are in most instances grouped for effect. *Hollies* and *Arctostaphylos* are however deficient in numbers, as are *Banabos*. The undulating nature of the ground favours the disposal of this, the outside or permanent part of the exhibition, but it has only been brought up to its present admirable condition by a considerable degree of skill and labour.

GROERS OF PLANTS FOR EFFECT.

In the largest class, that for a space capable of receiving 150 to 300 plants, an exceedingly choice group made by Mr. F. L. STUBBS; in this group there is a singular display of small plants, but the whole is all that could be wished. Immense specimen Palms form the background, these being finished off with finely-flowered *Azaleas*, *Rhododendrons*, and *Magnolias*, &c., with further colour effect by such plants as *Marantas*, *Calceolarias*, *Draena Lindenii*, &c. in all of which are finely done. This exhibit gained the Large Gold Medal, a prize of 300 marks, together with a special prize.

In another large class, the 2nd in point of size, Mr. G. SCHROEDER, of Hamburg, has a most excellent group, consisting of large Palms, and many other choice foliage plants, notably *Anthuriums*, *Alcistads*, *Pandanus*, *Caladiums*, &c., with choice *Orchids*, *Anaryllus*, &c., of flowering subjects, the whole forming a remarkably fine display, the reward being the premier prize in its class, with a special addition.

Another premier group in its class has for its colour effect chiefly *Pinus triloba*, and *Roses*, *Lilacs*, *Magnolias*, and *Azaleas*, all being well disposed, but striking the beholder as being a trifle too strong. This was from Mr. SEYDERTZ, of Hamburg.

Another group of fine-foliage plants alone, Mr. A. HAAGERMAN, of Hamburg, was easily 1st, the plants very clean and bright, and of a useful decorative size, and the effect was excellent.

FLOWERING PLANTS.

Orchids.—The finest collection beyond any question is that of Baron SCHROEDER. It embraces many of his choicest rarities; the *Odontoglossum* are very fine, as are likewise the *Cypripediums* and *Dendrobiums* (notably a plant of *D. infundibulatum*); an extra fine *Loddemansia* is also staged, as well as *Nandas*, the latter having suffered somewhat from frost. This is truly an h-oratory exhibit, but a Gold Medal was awarded to it.

Messrs. F. SANDER & Co. win the special prize of 100 marks, offered by Baron Schroder for a group of *Cattleya* Schroderae, this group including the very finest and best coloured examples.

Mr. G. O. ORCHID, of Lüneburg, Hamburg, is 1st, showing small plants in good condition, for the most part consisting of *Cattleyas*, with a few good *Odontoglossos*.

A rather smaller non-competing group, from Mr. C. SMUTZ, Wausbeck, contains some well-grown and freshly-developed examples of the best varieties of *Orchids*, and several particularly good rarities of *Lycaste Skinneri* and *Cattleya*.

For five specimen *Orchids* (small ones) there are only two exhibits, the best consisting of good plants of *Cypripedium villosum*, and *Cymbidium Chrysanthum*; these are shown by Mr. TREVOR, Wausbeck. In addition, there are some few exhibits in other parts of the show, but the *Orchids* do not compare favourably with English-grown examples.

Antias and *Rhododendrons*.—These are all important features in the show, the plants being loaded with bloom in all cases.

The large class for 100 plants brings forth a grand exhibit from Mr. C. PETERS, Ghent; these throughout bear blooms of large size, the varieties being of the best, the colours brilliant, various, and well-balanced; the predominant shape is that of the umbrells. With fifty smaller plants, Mr. PETERS is also 1st, the same fine quality being exhibited in this lot as in the bigger one, the form being that of a standard.

LIVERPOOL: *May*.—Average of the prices current at the undermentioned markets.—St. John's: Potatoes, 8d. to 10d. per peck; do., new, 5d. to 6d. per lb.; Asparagus, 3s. per cwt.; Cucumbers, 4d. to 6d. each; Carrots, 5s. to 6s. per cwt.; Mushrooms, 1s. 3d. per lb. *Birkhead*:—Potatoes, 8d. to 10d. per peck; do., new, 4d. to 6d. per lb.; Peas, 8d. per lb.; Asparagus, 2s. 6d. to 3s. 6d. per cwt.; Carrots, 5s. to 6d. each; Apples, 1s. per dozen; Gooseberries, 5d. per lb.; Grapes, foreign, 1s. do.; Cherries, 3d. to 4d.; Strawberries, 5s. per lb.; Mushrooms, 1s. 6d. do.; North Hay:—Potatoes, per cwt., Imperator, 2s. to 2s. 4d.; Giants, do.; Main Crop, 2s. 6d. to 3s.; Champions, 2s. to 2s. 4d.; Broccos, 2s. 4d. to 2s. 6d.; Swedes, 1s. 4d. to 1s. 6d. per cwt.; Carrots, 5s. to 6d.; Onions, foreign, 6s. 6d. to 7s. 4s.; Cucumbers, 2s. to 3s. per dozen; Cauliflowers, 1s. 6d. to 2s. 6d.; Cabbages, 10d. to 1s. 3d. do.

CORN.

AVERAGE PRICES OF BRITISH CORN (per imperial qr.), for the week ending May 1, and for the corresponding period of 1896, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

Description.	1896.		1897.		Difference.
	s. d.	s. d.	s. d.	s. d.	
Wheat	25	8	27	9	+ 2 1
Barley	23	6	20	5	- 3 1
Oats	14	3	17	3	+ 3 0

THE WEATHER.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1 continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

Directions.	TEMPERATURE.				RAINFALL.	BRIGHT SUN.

The districts indicated by number in the first column are the following:—
0, Scotland, N. Principal Wheat-producing Districts.—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. Principal Grazing, &c., Districts.—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; "Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending May 1, is furnished from the Meteorological Office:—

"The weather during this period was of two distinct types. During the earlier half of the week it was fine and dry in the north, and somewhat unsettled, with occasional rain over the southern districts, and with thunderstorms on Tuesday and Wednesday. Later on, the conditions improved very considerably in the south, but became unsettled and showery in the north.

"The temperature continued below the mean in Ireland and Scotland, but was rather above the normal in nearly all the English districts. Its range was considerable. The highest of the maxima, which were recorded on April 27 over England and Ireland, and on May 1 in Scotland, ranged from 70° in England, S.W., and 69° in England, S., and the Midland counties, to 60° in Scotland, W., and Ireland, S., and to 59° in Scotland, N. The lowest of the

minima were registered, as a rule, during the earlier part of the period. They ranged from 20° in Scotland, E., 28° in Scotland, N., and 30° in England, E., to 26° in England, S. and S.W., and to 44° in the Channel Islands. Frost occurred on the grass on some occasions in most parts of the kingdom.

"The rainfall did not differ very materially from the mean, being rather deficient in some districts, and a little in excess in others—more particularly in England, E.; while in Scotland, N., and England, S.E. and N.W., the fall just equalled the normal.

"The bright sunshine exceeded the mean in almost all the English districts, and also in Scotland, W.; in England, S.W., and the other parts of the kingdom the aggregate values were less than or just equal to the mean. The percentage of the possible duration ranged from 47 in England, N., and 44 in Scotland, W., to 25 in Scotland, N., and Ireland, S."

Obituary.

ELLACOMBE.—On the 30th April, at Bitten-Vicarage, Gloucestershire, EMILY ARBILLA, wife of Revd. Canon Ellacombe, Vicar of Bitten. R.I.P.

NOTICES TO CORRESPONDENTS.

A FOREIGN SEED: *B. A.* The seed sent is that of a species of *Mucuna*, apparently *M. urens*, a native of the West Indies and South America. It is known by the several names of Ass's-eye, Horse-eye, or Ox-eye Bean. *J. R. J.*

ANTS IN HOUSES: *C. N. M.* The *Baliicruciatu* Ant Destroyer. See paragraph in our present issue, p. 303. Also treacle in saucers, and carbolic acid.

APPLE BLOSSOMS WITHOUT PETALS: *Ecklinville*. Suppression of the petals in flowers of some varieties of Apple is not uncommon. It is a curious phenomena in your case, but will probably not hinder the blossoms from setting properly.

ACQUA BERRIES: *J. R. B.* When ripe, layer them in a small pit or large flower-pot with damp sand, say, two layers of berries and then a layer of sand, and so on. When the pulp is decayed, rub it off the seeds, and sow the latter in drills in the open, or in boxes 4 inches deep, filled with a sandy, loamy mixture, and keep in a cold pit till germination takes place.

A YELLOW ROSE FOR A HIGH GREENHOUSE: *L. E.* William Allan Richardson, Jaune Desprez, or Cloth of Gold. The first two are highly so noted.

BOOK-KEEPING: *W. S. G.* We are not aware of any book that teaches a method particularly suitable for the nursery trade. For learning Pitman's system of shorthand, you should obtain *Pitman's Shorthand*, of any bookseller.

BOOKS: *E. M.* Enquire of Mr. J. Douglas, Barking-ode, Hford.

CHRYSANTHEMUMS: *W. G.* We regret that it would be too great a demand upon our space to give you a list of all varieties of Chrysanthemums that should figure in one collection. Consult a cheap book upon the subject, such as that by Ed. Molyneux, or that by W. Wells. In the latter is given a selection of seventy-two varieties in dozens, according to their merit as exhibition varieties. The price of this book is 1s. from W. Wells, Earlswood Nurseries, Redhill, Surrey. In regard to your second question, consult Messrs. H. Cannell & Sons, Swanley.

CORRECTION.—Our valued correspondent, Herr Weddland, tells us that the *Wallichia* figured on p. 283 is *Wallichia disticha*, and not *W. densiflora*.

CUCUMBERS: *F. E. P.* The Cucumber is attacked by no fungoid disease, nor do the roots show the least trace of cell-worms. We suspect the injury is due to syringing during sunny weather with insufficient ventilation, hence scalding; or, possibly, to defective glass, which is a frequent means of plant-burping.

ELECTRO CULTURE: *X. Y. Z.* Experiments have been carried out, and the results embodied in their bulletins by the Massachusetts Agricultural College, Amherst, Mass.; and the College of Agriculture of the Cornell University, Ithaca, New York County, U.S.A.; and you could doubtless be supplied with the various bulletins on application to the College authorities. No such experiments, fully carried out, have been made in this country. Notices have appeared in this Journal, p. 790, vol. ix., 1894; pp. 816, 704, vol. 10, 1891; p. 42, vol. xi.,

1892; pp. 214, 311, 466, vol. xii., 1892; pp. 273, 394, vol. xiv., 1893; p. 143, vol. xv., 1894; pp. 221, 756, vol. xvi., 1894; pp. 14, 397, vol. xvii., 1895.

GARDENING ADVERTISING MEDIA: *X. Y. Z.* *Le Semaine Horticole*, 101, Rue Biliard, Brussels; *Revue Horticole*, Librairie Agricole de la Maison Rustique, Rue Jacob, Paris; *Revue de Horticulture*, *Belle*, M. Eward Pynaert, 132, Rue de Bruxelles, Ghent.

LATE PRUNING OF FRUIT TREES: *W. N. G.* The results of hard pruning on the fruit trees would be very late growth, and the consequent insufficient ripening of the shoots thus made, the lower parts of these being probably matured, but the upper parts would be immature, and likely to suffer from frost; but the entire length of shoot would ripen the next year, and probably set some fruit-buds on the more thoroughly ripened parts of shoots. The predisposing cause of ordinary canker is to be looked for in the soil, although there is a species of canker (gumming) brought about by frost rupturing the bark, and thus admitting fungus, *Nectria ditissima*.

LILIUM THOMSONIANUM OF LINDLEY: *W. T.* You are quite correct in your orthography. If you will consult the *Index Kewensis*, you will find there—*Frillaria Thomsoniana*, *L. Don* (1830), referred to *Lilium Thomsonianum*, *Lindl.* (1845), and *macrophylla*, *Don* (1825), to *Lilium roseum*, *Wall.* (1832); and *L. Thomsonianum* to *L. roseum*, *Wall.* Cat., whence we take it that if you think it is a *Frillaria*, you should call it *F. macrophylla*, *D. Don* (1825), but if you prefer to call it a *Lily*, then the name must be *L. roseum*, *Wallich* (1832). You will see by the dates given that the plant was named many years prior to Dr. Thomas Thomson's travels with Sir J. D. Hooker; but we have not at hand the books necessary for ascertaining who the Thomson was that is thus celebrated.

MUSHROOMS ATTACKED BY A MOULD: *H. T.* See answer to "A. E." in last week's issue of the *Gardener's Chronicle*.

NAME OF FRUIT: *Sir Chas. S.* We cannot say with any degree of certainty at this late season; skin much bruised.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.—H. M. E.* *Sempervivum arborescens*.—*J. R.*, *Villenois*. *Brassia Kelliana*, a species variety much in colour, that form set being sometimes called *B. cinnamomea*.—*C. H.* 1, *Epidendrum Stamfordianum*; 2, *Epidendrum alatum*.—*X. L. C.* *R. Phalaris arundinacea variegata*. Some seedsmen may supply seed, but the usual method of propagation is by means of the underground stolons, as in Couch-grass.—*J. G.* 1, *Bifrenaria maritima*; 2, *Dendrobium thrysiifolium*; 3, *Anthurium Scherzerianum*; 4, *Dendrobium primum*; 5, *Nepenthes molle*; 6, *Pteris serrulata cristata*; 7, *Euphorbia splendens*; 8, *Acalypha tricolor* or *Macleodiana*; specimen poor. We cannot name *Pelargonium* from leaves.—*T. Thompson*. 1, *Dendrobium undulatum*; 2, *Dendrobium Johannis*; 3, next week; 4, *Celsia celtica*; 5, *Epidendrum alpinum*.—*R. A.* Yes, *Tulipa sylvestris*. If the specimen was found wild, we should be pleased to learn the place in what locality it was found.—*X. Y. Z.* Probably, *Begonia chelonoides*.

RHOENODENDRON: *H. S. P.* If you can obtain good fibrous-plant leaf-mould, and some sort of sand free from sea-salt and iron, it would be wise to remove the plants and trench the beds, mixing with the staple a large proportion of the fresh materials, and replant at wider distances apart. Is the drainage of the land what it should be? Rhododendrons like a moist soil, but not one in which the water stagnates. Is lime found in large quantities in your soil?

XANTHOCHERAS SORBIFOLIA AND CARYOPTERIS MASTICANTHUS: *S. H.* *Neopora*. The first comes from Manchuria and Northern China, and was introduced by Pere David in 1895. The second was introduced by Fortune from China in 1844, and again later by Messrs. J. Veitch & Sons and others. It was figured in the *Gardener's Chronicle* for February 2, 1884, p. 149.

COMMUNICATIONS RECEIVED.—*Ludwig Müller*, Erfurt.—*S. G. E. T.*—*H. & M.*—*W. W.*—*W. & N.*—*Earl of Dufferin*.—*L. G.*—*H. W.*—*W. H.*—*De R.*—*H. H.*—*National Rose Society*.—*C. N.*—*J. G.*—*B. & S.*—*T. N.*—*X. Y. Z.*—*T. M.*—*D. W.*—*E. S.*—*T. S. B.*—*A. C. F.*—*D. T. F.*—*H. L. H.*—*J. H. C.*—*Barmer*.—*N. C.*—*L. G.*—*R. D.*—*J. J.*—*W. F.*—*R.*—*P. G.*—*F.*—*J. G.*

THE Gardeners' Chronicle.

SATURDAY, MAY 15, 1897.

RETROGRADE SELECTION.

I SHOULD be grateful if any of your correspondents would kindly give advice on the details of an experiment I have in prospect. Suggestions are more especially desired as to the most suitable plants for the purpose.

The experiment is intended to be carried on by a process of "backward selection," or in the opposite direction to that followed by breeders, whether of plants or animals, when they attempt to create a new variety. They select for the parents of each coming generation those individuals of their experimental stock, whose characteristics approach most nearly to the ideal type pictured in their imagination. My aim is the very reverse of this: it is to begin with a variety that has become established, and to breed back to the original form. The primary object is to learn the number of generations that must elapse before the original form is reached, under specified conditions of culture and selection. By this process it is hoped that a practical means of measuring the stability of strains, varieties and races, may ultimately become systematised, that more light will be thrown on the steps through which changes of type take place, and that many matters of high theoretical importance may be cleared up, relating to the distribution of variations and to the varying degrees of continuity or discontinuity in regression, which are too technical to be discussed here.

Whatever may be ultimately done in this direction, it seems clear that the earlier attempts should be conducted under the easiest conditions, and especially by employing the plant that seems best adapted to the purpose. The principal desiderata are: that it should be a hardy annual, in extensive cultivation, consisting of an original race, and of a distinct and well-established variety that has been recognised for a considerable time. Also that the plants, both of the original race and of the variety, should admit of being grown in a healthy state, in small flower-pots. It would further greatly facilitate the experiment if the main difference between the race and the variety lay simply in their sizes, the one being a dwarf form of the other. Anyhow for the first trial, a plant ought to be employed in which the differences are, in some way, strictly measurable. Units of length are serviceable for height of plant and for length and breadth of leaves, &c.; units of number, for number of leaves, spots, serrations, &c.; units of time, for period of sprouting, budding, &c.

The first enquiry that I make is, What plants best fulfil the above requirements?

Next, as to the soil in which to grow them, for the tendency of a variety to relapse into its original form greatly depends on the character of the soil. There are two desiderata to be fulfilled. The first is, that whatever soil be

employed, its quality should admit of clear definition, so that the experiment could be simultaneously carried on by different persons, and be hereafter repeated under precisely similar conditions, so far as that important element is concerned. The second desideratum is not immediately felt, as it relates to the possibility of future experiments of the same general character being hereafter made on numerous different plants, in which case it would be well to employ a limited number of different and well-specified soils, or perhaps only two of them, a light and a heavy, with possibly the occasional mixture of some definite dose of a chemical ingredient. A reasonable method of meeting the difficulty would be to obtain the soil annually from localities well known for their horticultural and chemical peculiarities. Therefore, the second enquiry that I make is, What well-defined soils would be suitable for these experiments?

There are many other details of procedure that require to be determined, referring to mode of planting, exposure, watering, avoidance of cross-fertilisation, &c., which could no doubt be clearly systematised on a carefully-considered plan, so as to ensure uniformity of treatment by different experimenters, but I will not at present ask particularly about these.

Assuming that we have fixed on a plant of the original stock *r*, and on its variety *v*, severally planted in suitable and specified soils, and that the experimental series *x*, planted in the same soil as *r*, is intended to change *v* back into *r*, the proposed experiment would be something of the following form:—There would be a few, say a dozen, specimens of both *r* and *v*, and fully 100 of *x*, each planted in a separate flower-pot, requiring the use of some 124 pots altogether. *r* and *v* would be annually raised from seeds procured from the same seedsman, to serve as references, for they and the experimental set would be equally affected by the varying peculiarities of the climate, &c., in different years, as well as by the permanent environments of the locality.

For simplicity of explanation, let us suppose the noticeable difference between *r* and *v* to consist in their height at the time when they begin to bud, *v* being a dwarf variety. Also that the change backwards occurs gradually, and not by sudden jumps on the part of individual plants. Some days before the expected period of budding, a provisional attempt would be made to so arrange the pots that the plants shall stand in orderly sequence, beginning with the shortest, and ending with the tallest. The pots of *r* and of *v* would be arranged on the same principle. When the buds begin to show, the orderly arrangement of the three sets would be carefully and finally revised, and the class-place of each plant in its respective series would be chalked on its pot, No. 1 signifying the lowest place. Consequently the two middlemost of the *r* series would be 5 and 6, the two middlemost of the *v* series would also be 5 and 6, while those of the *x* series would be 50 and 51. A single class-place makes little difference except towards the extreme ends. The next step is to see by direct comparison whether *r* 5 or *r* 6 coincides in height with any one of the *v* series, placing them on either side of it. In the first year, probably, the middlemost of the *r* would be taller than the tallest of the *v* set. In that case, set aside the, say, five tallest of *v*, viz., Nos. 96 to 100 for seeding, and pinch off every bud from every other plant of all the sets, so that no risk of cross-fertilisation may subsequently

arise, while a sufficient number of seed-plants are preserved to avoid the injurious effects on their offspring of close interbreeding. Or it may happen, if not in the first year, then in some subsequent year of the experiment, that a match to *r* 5 or *r* 6 may be found at some particular class-place in the *x* series, say at the 80th class-place. Then keep Nos. 78, 79, 80, 81, 82 for seed, and destroy all other buds as before. In all cases, make an exactly similar comparison between *v* 5 and *v* 6 and the *x* series. Lastly, obtain a photographic record of all the three series of plants, *x*, *r*, *v*, by putting the pots in orderly arrangement, with their chalked sides foremost, upon five shelves fixed to a vertical wall, twenty-five on each shelf; then setting the camera squarely in front of them, the whole can be photographed on one plate, without distortion. Tapes of inches, or the like, should be fixed to the shelves to give the scale of the photograph. By these means every desirable measurement of the plants admits of being leisurely made by the statistician, who will treat his measurements according to modern methods, and deduce the required information from them.

Proceeding year after year in this way, the mean height of *x* will increase, but it would be inadvisable to wait until the middlemost plant of *x* closely coincided with the middlemost of *r*. The increase in height of *x* may be very rapid during the earlier years, but will become gradually slower, and at length so slow that close coincidence will not occur for a long time; and, again, when it does so, the precise epoch could not be determined with confidence. It would be much better to complete the experiment at an earlier stage. That which I would propose is the first year on which the *x*-plant, which occupies the 75th class-place, in a series of 100, fairly coincides in height with the middlemost of *r*. Technically, this would be termed the "upper quartile" *x*-plant, because it stands one-quarter of the way down from the top-end of the class. The height of the upper quartile plant (as of that occupying any other specified class-place), is independent of the number of plants in the series, so long as they are sufficiently numerous for statistical purposes. The upper quartile is very easily ascertained, whatever the number of the plants in the series may be; it is an easily-remembered class-place, and it is one that plays an important part in the higher methods of statistics. Had *v* been a large variety, and not a dwarf variety of *r*, the lower quartile, or the twenty-fifth plant in a series of 100, would have been employed.

It is hardly necessary here to speak at length on such changes of the process as would be needed in the very probable event of some few of the *x*-plants making a sudden change to *r*, because the reader can easily foresee them.

The process just described, except the photographic part of it, is not restricted to single and measurable characteristics, but is generally applicable, so long as the individuals admit of being classed in orderly sequence, whether by measurements, by intercomparison, or by marks awarded according to the judgment of an examiner. Thus, when plants, or animals, are submitted to prize competitions, the judges have to take simultaneous note of numerous "points," and to give their marks and classify accordingly, and they do so with fair precision, as shown by the accordance between the judgments of different experts. Therefore, although the measurement of a single character and the

opportunity of direct intercomparison by moving the flower-pots into different positions, may reasonably be insisted on in the earlier experiments, a much wider field of work lies open to the future, after the practicability of the simplest and most direct method shall have been assured.

I am painfully conscious of the shortcomings of this too brief sketch of the details and of the full purport of the experiment in view; but I send it all the same, because it adequately explains what I am particularly desirous to learn, and because a complete explanation would take up too much space, and be necessarily very technical. Should further information of the latter kind be desired, I would refer to a paper and calculations just published by myself in *Nature*, April 29, p. 605, which I worked out with reference to one phase of this very topic. Francis Galton, 42, Rutland Gate, London.

AQUILEGIAS.

THERE are not many flowers that possess higher qualifications than these for garden cultivation. I am greatly surprised that their culture should be comparatively limited in Scotland, where they can always be grown successfully. They are for the most part hardy, vigorous in growth (especially the hybrids from *A. cœrulea* and *A. chrysantha*), and highly decorative in general effect. Many of them are contemporaneous in their period of bloom—such, for example, are the "Canadian" and the "Golden" Columbies, which are, in my opinion, the most reliable, hardiest in character, and longest lived of all. They are not less valuable than the fragrant *Viola* and the many-coloured Spanish *Iris* for artistic value; but, unlike those somewhat effervescent flowers, they survive for many years even in situations where other more tender plants would soon die.

Aquilegas, like many other alpine and herbaceous plants, have a wide distribution. They are chiefly discoverable among the loftier mountain ranges of Europe, Asia, and America. We need not, therefore, be surprised at their capability of enduring the great severity of frost, when we remember the regions whence they have come. Indeed, it may be said that so far as regards such truly alpine forms as *A. glandulosa*, which finds itself at home in the Highlands of Scotland, a comparatively cold climate is requisite for their success. It has been asserted by several writers on *Aquilegas* that many of the finest varieties of the plants require to be treated as biennials, and grown periodically from seed to ensure perpetuation; but I find that this is not necessary, in my part of the country at least, for the continued existence of *A. cœrulea hybrida*, *A. canadensis*, or *A. chrysantha*, which, so far from perishing prematurely, like their unreliable associate, *A. glandulosa*, after one short season of limited bloom, seem to grow stronger and more massive every year. It is possible that they might be found more transitory if grown further south; yet I cannot but remember that some of the grandest hybrids from *cœrulea*, *chrysantha*, and other notable varieties have been cultivated as perennials by the Messrs. Veitch of Chelsea, Mr. Thomas Francis Rivers of Sawbridgeworth in Hertfordshire, and Mr. Harry Turner of the Royal Nurseries at Slough, all of whom are enthusiastic admirers, like myself, of this Orchid-rooted flower.

It is somewhat remarkable that the Scottish cultivator, who has given us the most vigorous and the most enduring, also, perhaps, the loveliest and most fragrant of *Violas*—the miniature, rayless variety, entitled *Violetta*—should also have originated the most exensively beautiful of all *Aquilegas*, viz., *A. Stuarti*, a highly interesting hybrid (as I am informed by the raiser), between *A. glandulosa* and *A. Witmanniana*, which requires to be treated invariably as a biennial, and cultivated very carefully in deep, fertile soil. It was, I understand, named by the late Professor Balfour at Edinburgh, and introduced into cultivation by Messrs. Cocker of Aberdeen.

I am free to confess that, notwithstanding all my

efforts, I have not hitherto been very successful with *Aquilegia Stuarti*, probably because the best situations in my garden having been previously occupied by *Roses*, *Tigridias*, *Iris*es, *Narcissi*, and *Eastern Lilies*, I was unable to give it a sufficiently rich soil; and though I have had it occasionally in flower, I have found that its blooms, however imposing in dimensions and artistic in aspect, are comparatively rare. Nevertheless I affirm, that notwithstanding the limitations indicated, it is well worth growing for its attractiveness. It is a distinct advance on *Aquilegia glandulosa*.

One of the finest and earliest in flowering of the Californian varieties is *A. cœrulea hybrida*, manifestly a cross between *A. cœrulea* and *chrysantha*; for the former, which precedes this fine hybrid by nearly a fortnight, is entirely destitute of any primrose hue, which consequently was the result of cross-fertilisation. This, possibly, may have been the work of insects. Here this variety, not less than its parent, is a true perennial, demanding little attention in summer, no protection in winter, and showing no diminution in vitality at the end of ten years. *Aquilegia Skiunerii*, a native of the northern regions of South America, I have not found so vigorous as *A. californica* or *A. canadensis*, of which the former, with its brilliant scarlet hues, is unquestionably one of the showiest of all the American Columbies. It is even finer than *A. canadensis*, which, I am informed, originally came to this country from Virginia. Its grows abundantly in the North American forests, and generally in extremely rocky situations. It is, I may incidentally observe, a variation from this interesting flower, of considerably stronger constitution than the original, which is generally cultivated in European gardens. I have not found it under any circumstances or climatic conditions arduous of cultivation, having experienced much more difficulty with other varieties, such as *A. alpina superba*, *A. glandulosa*, and—as I have indicated—*A. Stuarti*. Among the most beautiful of recent hybrids are those which have been raised and introduced by the Messrs. Veitch; many of these have a very distinguished appearance, quite unlike that of their predecessors, for which reason they are worthy of general cultivation.

A celebrated writer on Rose-culture has somewhere said, that if he were strictly limited by any unkind fate to one variety of the Rose, he would choose that most vigorous and most prolific of all climbing varieties, *Gloire de Dijon*. If I were similarly restricted with reference to *Aquilegas*, I would, without hesitation, and for similar reasons, select the beautiful *Aquilegia chrysantha*. A plant stronger in constitution, more exuberant in growth, more luxuriant in flowering, and more singularly artistic in floral formation, and in aspect, for garden ornamentation does not exist. *David R. Williamson*.

AMERICAN NOTES.

NEW VARIETIES OF FRUITS.

The report of the Pomologist of the United States Department of Agriculture for 1895 has just been distributed, and though as tardy as any Government document, it is worth notice. As usual, the matter of greatest importance is the report on "Promising New Fruits," under which head are described the various Apples, Pears, Plums, &c., which have been recently introduced and brought to the notice of the Division of Pomology. The list includes 100 varieties of Apples, mostly quite new, 13 varieties of Pears, 3 of Apricots, 11 of Cherries, 25 of Peaches, 17 of Plums, 2 of Grapes, 4 of Oranges, and 1 of Pomelo. This record for a single year indicates that the American fruit list is increasing with all desirable rapidity. Of course, these records represent a very large country, with many very diverse conditions, wherein a considerable number of these varieties achieve only a local importance. But it is easy to see that our fruit list will soon become so tremendous as to frighten the conscientious student of pomology; and a complete revision of Mr. Downing's book has

already become an impossibility. It may also be seriously doubted whether the further wholesale introduction of new varieties, especially to the Apple list, is worth while.

Of the introductions in question, two of the varieties of Apple, one of Apricot, and four of Cherry, are of Russian or Polish origin. A great deal has been said in recent years about the additions to the American fruit list from the Russian importations; but it is probable that the figures here given represent with fair accuracy the relative importance of those introductions. The Russian fruits are making proportionally much the greatest headway in the Cherry list. The Russian Apples are gaining some attention in very cold sections of the States and the Dominion, while the Russian Plums remain practically unknown. The American fruit list is growing to be more and more—almost exclusively—American, which means only that American seedlings are proving to be better adapted to local conditions than their parent varieties imported from Europe. And that is only what might have been expected.

FOREST RESERVATIONS.

A strong fight is being made at Washington against the large forest reservations made by President Cleveland during the last days of his administration. Cattle-men, miners, railroad men, and many other private interests with which the reservations interfere, are bringing every political influence to bear on President McKinley and on Congress to have the order rescinded. It seems probable at the present time that some concessional modifications may be made in the executive proclamation of reservation, but it is hoped and believed that no general abrogation of the order will be attempted. *F. A. Waugh, Burlington, Vermont, April 23.*

METHODS OF PROPAGATION.

(Continued from p. 285.)

CONIFERS FROM SEED.—If only a few trees or shrubs of any kind are required, and it is desired to raise them from seed, sow the seed in boxes or seed-pans, and place them in a cold pit, where they should be watered as often as necessary. Transplant the seedlings into the quarters as soon as they are large enough, and thus prevent the roots becoming matted together. Conifers are always best when raised from seed; they can then develop naturally to the acute pyramidal form, that makes these trees so useful to the landscape gardener. When planted for ornamental purposes, they should never be crowded, but if grown for timber only, it is necessary to plant them closely, as they draw one another up, as it is called, and may be thinned out when they reach the desired height by simply cutting down, as they do not, like many other trees, "stool," or throw up young growth from their roots. The cones generally do not attain maturity till the second year after forming. The structure of the wood, as viewed in section under the microscope, is unique, the pitted cells, which are always present, determining at once that the tree from which the section has been cut was a Conifer. The most important northern timber tree belong to this order, but a few only are grown largely in this country as forest trees, the great bulk of the Fir timber being imported from Norway and Sweden, from Canada, and other parts of the New World. But this need not be a permanent condition, as thousands of acres of land which are now almost idle might be profitably employed to grow this class of timber. The seeds of all the genus are securely imbedded in the cones, and in some cases are very difficult to free.

The cones should be collected in late autumn, and stored in a dry warm place, in boxes, such as that over the hot-water boiler, where the temperature is regular and dry. Thus treated the scales of the cone will split open, and the seeds will generally be freed, if the cone be taken in the hand and struck sharply at its point on some hard substance. Having fanned away the scales and abortive seeds, the rest may be sown in light peaty soil, in an outside pit, protected in bad weather by reed or straw movable lights, or if there is much quantity the seed may be sown at

once into beds in the open air. In the case of the Larch, Scotch Fir, and other hardy kinds, this is preferable, but the exotic species need some kind of protection.

The small seeds of the Larch separate freely from the cones, if these be kiln dried; but for a small

without so tedious that it is often imperative to saw them through in the direction of their axis, to get out the seed; while in contrast to this, the seeds of the Araucarias are as large as Brazil-nuts, and come freely from the immense cones, by simply drying them gradually. These seeds are edible when cooked like

will descend into the soil; but the first young about will often not appear till the following year, or it may even take eighteen months to show itself above the level of the soil. As soon as these attain to 4 inches in length they may be lifted, and either potted at once into single 3-inch pots, or into stores, viz., 5 or 6 inch pots, placing four to six round in nursery beds at once. If potted singly, take care they do not get corkscrew-rooted, and are shifted into a larger-sized pot as soon as the roots touch the pot.

It may be here noted that the seeds of Conifers do not do well as a rule if covered heavily with soil; half an inch deep will be ample for most kinds, but for the small light seeds of the Thujas and Cypresses, half this depth will suffice. The surface of the soil should be covered with moss or Cocoa-nut fibre, to keep the soil uniformly moist and warm. It is better not to use artificial heat, though the gentle warmth of a spout hot-bed will do no harm, especially when the seed has been three weeks or a month in the soil.

The Lebanon and Deodar Cedars are both raised from seed in nurseries, but it is rare, at any rate, except in the south, for good, ripe seed to be produced, though I have seen some fully-matured cones in Sussex and Kent. Cephalotaxus, Juniperus, Podocarpus, and Taxus, are usually treated alike when raised from seed. The berries are gathered when quite soft and ripe, and either rubbed in sand to get rid of the sticky pulp that envelops the seeds, or dried, and then sown thinly in boxes and pans, the first method being the quicker of the two, and certainly preferable for the Yews, the berries of which are very full of a sticky, sweet juice, that makes them attractive to birds, especially the thrush tribe.

Varieties of Conifers do not reproduce themselves true from seed, so that if it is desired to perpetuate any one form, the only sure way is to graft, or to raise it from cuttings or layers. *Experience.*

(To be continued.)

LATHYRUS SPLENDENS.

This handsome creeper has been in flower for some time past in the Cape House at Kew, where its brilliant scarlet flowers attract much attention. It has been likened to a Sweet Pea, but to our thinking is more like the perennial Pea. It is a native of California, and is known as the "Pride of California." For the specimen whence our illustration (fig. 106) was taken, we are indebted to the authorities at Kew.

CASTLEROY, BROUGHTY FERRY.

A SHORT climb, a week or two since, brought me to the summit of Castleroy, the residence of Mrs. Gilroy, where the scent of the sea and the odour of the Austrian Pine and spring flowers saluted me. The sea is about a quarter of a mile distant. Castleroy, a handsome modern mansion, is about 150 feet above sea-level, and commands distant views. It is unsheltered from either the north or the south; and the chief portions of the gardens are on the crest of the brae or hill, and these are fully exposed to the wind on either side of the incline. When it is known that this exposed garden stands on an impenetrable stratum of rock, the wonder increases that so many crops and plants are found in such fine condition.

The whole of the soil has been carried up by the present gardener, and for twenty years or more the garden has been in course of construction, and much of it, previous to planting, has had to be made again and again, because trees and shrubs, after being established, have had their leading and other shoots snapped by the wind, or have been torn out by the roots. Disasters such as these have, however, neither daunted the courage, nor exhausted the resources, of Mr. Dickson, the gardener, who has won many striking victories over the elements on this bleak hill-top during the last twenty or more years.

FIG. 106.—LATHYRUS SPLENDENS: FLOWERS SCARLET (KEW).

quantity one may use a large earthen pan, into which put the mature cones in a thin layer, and then place the pan on the hot-water pipes in a forcing-house, when the scales will split asunder, and the seeds will fall into the pan; but be careful to avoid overheating, or the germ may be killed.

The cones of some of the Alices, notably *Webbiana* and *grandis*, are not only very hard and compact, but

Chestnuts over a slow fire, and, according to Humboldt, form the staple vegetable food of some Indian tribes. The best way to put these into the soil is to hold them by the thick rounded end between the finger and thumb, and to push the pointed end into the soil as thickly as the cook puts raisins into a pudding, at an angle of about 45°. The radicle in three weeks or a month, according to the freshness of the seed,

For example, most cultivators prune their shrubs and trees to improve the beauty or convenience of their sky-lines, enhance their fertility, or support or subside the effect of surrounding objects. But Mr. Dickson's first necessity was to prune his plants, so as to reduce their size, and render them less liable to injury from the storms. Conifers and other plants, lifted and planted intact, are often swept clean out of the soil; hence, branches and stems are reduced, and soil is heaped over the roots of the trees to more than average depth, this additional mechanical weight affording increased anchorage to the roots.

I noticed an excellent method to secure a maximum of shelter at a minimum of labour. In all gardens there is waste, and its final destination is the fire heap. At Castlerey, every form and variety of waste was and is converted into shelter. Prunings, up-rooted, diseased trees or shrubs, and rubbish of all sorts, are built up into banks or rough boundary lines, and made thus to furnish the ever-desired shelter at exposed points, earth being freely mixed with this debris, and trailing plants set out, as well as annuals sown or planted, so that some of these shelters are objects of beauty of a very original character. Much skill and forethought are also displayed in the selection of the best sites for fruit-trees and bushes, vegetables, and flowers; and the space being limited in extent, the utmost is made of it by means of walks, shrubberies, lawns, flower-beds, and borders; and so well have these features been planned and carried out, that, exposed as the site is, there are few days in the year that some sheltered spot cannot be found for exercise or repose in the open air.

Within a few yards of each other in these gardens, the most perfect shelter and the most desolate exposure may be found. The views are wide and pleasing, and take in the mouth of the Tay and the open sea. Far away on the land side is a narrow fertile plain, backed by mountains in the distance. On the highest point of the ground towards the centre, what is known as the Dalkeith curved group of beds is placed; and mainly furnished with hardy *Chrysanthemums*. Near here, too, is a Rose arbour, in which the hardier Teas and other Roses, including Turner's Crimson Rambler, thrive. Roses also grow well in other parts of the grounds, while just over the hill the Broughty Ferry Rosary of the Messrs. Crolls may be said to join the picturesque and beautiful gardens of Castlerey.

The growth of trees is somewhat slow, especially after they reach a height of 20 feet. Most of them hesitate to go higher, because of the wind, and the result is peculiar; other leaders rushing up to the front, where the first have been arrested, being stopped in turn. Hence the tendency of most of the trees to spread, instead of growing upwards. Mr. Dickson put the matter yet more pithily, by remarking that of those at Castlerey, "the Weeping Birch went straight up the best."

The Austrian Pine is by far the best Conifer, but it is very difficult to keep erect when it gets to a large size. Several other Pines do fairly well, but none approaches the Austrian as a wind-resister, and it seems to thrive on the salt spray, and only suffers check or wreckage from the strength of the wind above and the lightness of the soil below, as already described.

Spruces and Silver Firs will only grow when they are young, and surrounded by other trees, and are of no use alone, the exposure killing them, the common Spruce being as bad as the rest. Of deciduous trees, the two best are the Oriental Plane and the Weeping Birch; the Beech, purple Beech, Roman or Mountain Ash, Service-tree, Norway Maples, Geans, Prunus Pissardi, and others, also thrive fairly well. Horse-Chestnuts and Limes also grow pretty freely, but the Chestnuts especially look weather-beaten after a few severe tosses with the wind and the brine.

The Sweet Bay, and varieties of Cherry Laurel, such as *rotundifolia* and *calceica*, Mr. Dickson considers his most valuable evergreens. He propagates and plants these by the thousand on banks, edges of shrubberies, and as undergrowth or shelter to other trees or shrubs. Their shining green leaves seem wholly indifferent to the fiercest winds and the

sea spray, and I have never seen a finer, healthier stock of these two Laurels than in this wind-swept garden.

The Holly is perfectly hardy, but grows slowly. Rhododendrons are not a great success, owing chiefly to the dryness and thinness of the soil, 18 inches to the solid rock being a fair average.

All Weigelas grow freely, and make a brilliant show in season. The Mock Oranges grow freely, and bloom profusely. Spiræas, all the shrubby species do well, *S. arifolia* and *S. Lindleyana* especially so, and they are grown extensively. The beautiful New Zealand shrub, *Olearia Haastii*, is quite at home, and reaches its highest beauty in August; it may safely be added to sea-side plants anywhere, and will make a splendid companion to the Sea Buckthorn. The *Ailanthus glandulosa* grows rapidly, and looks well, headed down to the ground every year. *Laurostium* lives and grows, but never blooms—altitude too high for it. Cupressus of sorts are fairly hardy, but need the shelter of other trees.

Of American *Arbor-vitæ*, there are several of the varieties which do well, and furnish valuable plants for clothing the ground in winter. Several *Leucosporas* thrive well in a young small state. *Dimorphanthus manchesteriensis* has fine foliage, and thrives in these gardens. *Diplopappus chrysophyllus* thrives and blooms beautifully here every year, as does also the all-too-seldom-seen *Colutea cruenta*. It should be stated in connection with these and other shrubs in these gardens, that Mr. Gilroy, the son of the present owner, travels a good deal abroad, and makes large collections of plants, trees, and shrubs for Castlerey Gardens.

Fruit, flowers, and vegetables, inside and out, are well grown in these elevated gardens. There are also a large conservatory and greenhouse, and two lofty rosy vineeries, span-roofed, 80 feet long, 15 feet high, and 21 wide. One is furnished with Hamburghs; the late house, with Lady Downe's, Alicante, Trebbiano, Gros Maroc, and Gros Colmar. The Vines have seen many fine crops, and are still vigorous and healthy. If there are to be any Diamond Jubilee Medals this year, and they are given to those who have vanquished the greatest difficulties in commanding horticultural success, surely Mr. Dickson has earned high honours for making this wind-raked, sea-washed crown of Castlerey rejoice and blossom as the Rose. *D. T. F.*

LILIUM HARRISII AND THE ELECTRIC LIGHT.

At a recent meeting of the Horticulturists' Club of Cornell University, Mr. G. Kains presented notes of experiments with the Easter Lily. As to the effects of the electric light in its cultivation, he said that the bulbs were potted in the middle of October, plunged in a solid bed late in December, and the electric light turned on January 1. A globeless arc lamp was used. It burned from 5 P.M. until 6 A.M. daily for the following four months. The bed was divided into three sections. The first was exposed to the full glare of the naked light; in the second, the light passed through a large pane of glass, which cut out some of the ultra violet rays, but did not impede the passage of the light; in the third section was separated from the light by a black canvas curtain, which was drawn across the bed each night before the lamp was lighted. When the light was first turned on, the plants were of uniform development, but in six weeks changes appeared in the foliage, which gradually became more pronounced. The plants in the lighted sections grew very tall and spindling, had long peduncles, narrow and saw-toothed, very much curved leaves, far apart on the stems. These effects were most apparent under the naked light. The plants in the unlighted section were more robust, had deep, glossy-green leaves, were more stocky, less subject to disease, and, on the whole, more evenly developed. After the buds were formed these differences did not become more pronounced, but the buds under the naked light soon began to show a dark brown streak on the surface most exposed to the direct rays from the lamp, and this burn increased

as the buds grew and expanded into blossoms. The seared petals were much more curled than is ordinarily the case with healthy blossoms, and the stripes of brown were in some cases a quarter of an inch wide on each of three petals. No such trouble was experienced with the plants in the light which had passed through the pane of glass. The earliest flowers appeared on plants in the naked light, and in this section they lasted on the average nine days. Four days later the plants in section two flowered, and lasted here nine and a half days. The plants in the unlighted section were nine days later than those in section two in coming into blossom; but the flowers, though slightly smaller, lasted eleven days, and were more robust. The flowers in the lighted sections, like the plants which bore them, were spindling, but not unsightly, excepting those which were burned.

A plant with two remarkably evenly developed stems was taken from the unlighted section, and so placed that the curtain could be drawn between them, the one stem being in the unlighted section, the other among the plants behind the pane of glass in section two. A second twin-stemmed plant was also taken from the unlighted plot and placed in the naked light, but the larger of the two stems was covered each night with a tube of manilla-paper to exclude the light entirely. In each case the stem in the light blossomed a day before the other stem. Some other plants of uniform development were marked, and a part of them removed to the lighted sections, the others being left in section three. The former blossomed seven days before the latter, the last blossom in the former group being three days earlier than the first blossom in the latter group. The blossoms were perfectly healthy, and lasted as long as those in the unlighted section. From these experiments it is concluded that it will probably pay commercially to use electric light in cultivating *Lilium Harrisii* when the buds are an inch long, in order to hasten their expansion, and that the light must pass through glass to avoid burning the petals. *S., in Garden and Forest.*

PROGRESS OF THE CYCLAMEN.*

On the occasion of the discussion on "Variation in Plants and Animals," which took place on February 25, 1895, it occurred to me that it might be useful to give an illustration of the amount of change which had been effected in a plant by continuous selection under cultivation in a comparatively short time. I, therefore, placed upon the table an example of the wild and of the cultivated form of the garden "*Cineraria*" (*C. cruenta*).

The choice of this species was purely accidental. It was, however, violently impugned. It was contended that the garden *Cineraria* was not the result of the development of a single species, but that it was of multiple origin, and the result of the intercrossing of several species. It was further contended that its change from the wild form had not been gradual, but by discontinuous steps or "sports." Neither contention seemed to me well founded. But I admit that, owing to the lapse of time since the so-called "improvement" of the *Cineraria* commenced, it is impossible to give formal proof that the process has been what I described. Mr. Darwin met with the same difficulty. He remarks: "We know hardly anything about the origin or history of any of our domestic breeds."† As is, however, well known, he regarded them as the result of accumulation by selection of successive slight variations. But he also tells us that "the chance will be infinitely small of any record having been preserved of such slow, very long, and insensible changes."

It seemed to me important, therefore, to obtain the history of some cultivated plant which would not be open to the objections urged in the case of the *Cineraria*.

After some consideration, I selected the plant known in gardens as *Cyclamen persicum*. Owing to

* "The cultural evolution of *Cyclamen latifolium*, *Sibthorp.*" By W. T. Hisseton Dyer, C.M.G., C.I.E., F.R.S. Read March 18, 1897, before the Royal Society.

† *Origin*, 6th ed., p. 22.

the kindness of the skilful horticulturists who have worked upon it, I am able to place on record a nearly complete history of the changes it has undergone.

The genus *Cyclamen* belongs to the order Primulaceæ, which in its affinities is somewhat isolated. *Cyclamen* itself is distinguished from the rest of the tribe Lysimachiæ, to which it belongs, by the reflexed segments of the corolla.

Cyclamen persicum, Miller, is a name given by gardeners to a form slightly modified by cultivation of *C. latifolium*, Sibthorp, a species confined to Greece

and Syria. The vated forms in existence are descendants from this one individual. The assertion cannot be proved, but is not improbable; it is known to have been a variety with white flowers. As will be shown, the forms now in cultivation have been derived from a white-flowered one, which in turn might well have been derived from the Lilla plant.

Such a modified form was, in fact, that described by Miller, in 1768, in the eighth edition of his *Gardeners' Dictionary*, under the name of *Cyclamen persicum*. He describes the flowers as "pure white

Early in the century some colour variations were in cultivation. Several as well as the typical *C. persicum* were figured in the *Flore des Serres* in 1877, t. 2315. These record the amount of change from the wild type which had been accomplished in a century and a half. One striking seminal sport (*C. persicum*, var. *laciniatum*) is figured in the *Botanical Register* in 1827, t. 1095. It is remarkable for spreading corolla segments broader than usual, and cut at the edges. It does not appear to have been perpetuated, but in some degree it anticipated some of the remarkable modern developments.

I am informed by Mr. James Martin, the accomplished propagator of Messrs. Sutton, that the recent remarkable development of the *Cyclamen* began about 1860, and, at any rate in their hands, started with the old "crimson and white." It will be seen from the accompanying figures how little this differs from the wild type. Fig. 107 represents a flower of the latter from a plant imported by Messrs. Sutton from Syria after six years of cultivation; it is not appreciably altered. Fig. 108 represents a flower of their "crimson and white;" it only differs from the wild type in having shorter, broader, and less twisted corolla segments.

In considering the progress which has been made since 1860 under the skilful hands of Mr. Martin and others, it is important to bear in mind that there is no question of hybridity. *Cyclamen latifolium* has resisted every attempt to cross it with any other species. We are dealing, then, with the evolution under artificial conditions of a single species. Further, in the following statement, I have confined myself to the result of continued self-fertilisation, and have not thought it necessary to indicate the results of crossing races which have assumed characters more or less distinct.

NOTE.—Mr. Martin strongly insists on the principle laid down by Mr. Darwin from de Vilmorin, that "the first step is to get the plant to vary in any manner whatever." As Mr. Martin puts it, "the breeder must work with nature." It is his practice to seize the smallest deviation, even so small an indication as the slightest difference in a cotyledon of a germinating seed. The first direction of work would, however, for commercial purposes, be to develop the size of the corolla. Messrs. Sutton have sent me photographs of the largest flowers hitherto produced by them. [We give at fig. 109 an illustration of real size of a variety recently exhibited. Ed.] These represent the continuous work of forty years. As the work was not done for a scientific purpose, the whole of the progressive steps have not been preserved or recorded. But Mr. Martin denies that they have been attained by other than progressive selection, or that they have been reached by leaps and bounds. In developing any particular character it is, to use his own words, always done by a "ladder," i.e., continuous self-fertilisation and selection. One stage owes its preservation to its having retained fragrance. Beyond this stage fragrance has been lost.

An interesting question is whether there is any limit to the extent to which an organ can be developed, and if so, what? It is to be hoped that Mr. Martin will continue his work in this direction, and strive, if only as a matter of scientific interest, to increase the size of the corolla to the maximum possible. The only check will probably be found to be the general balance of nutrition.

Spreading.—I was much struck to find amongst a magnificent series of specimens, kindly sent me by Messrs. Sutton, forms with the segments of the corolla spreading instead of reflexed. I have received even more striking examples from Messrs. Hugh Low & Co. This is remarkable because, as I have already pointed out, the latter is a distinctive generic character in *Cyclamen*. Although the alteration in the appearance of the flower is enormous, the structural change is slight; it is merely a matter of direction of growth. It amounts, however, to the loss of a generic character, and a reversion to a more generalised type. The change is therefore essentially atavistic.

and Syria. There is a good figure of the type in Sibthorp's *Flores Græcæ* t. 185; it has pink flowers, with a ring of darker colour at the throat. The species is said to have been first cultivated in Europe at Lille in 1731,* having been introduced from Persia. There must have been some error as to its origin, for Boissier points out that the species is not found in that country.† In all probability it was obtained from Syria. The Lille plant ultimately went to Ghent, and it has been asserted that all the culti-

with a bright purple bottom" It was figured in the *Botanical Magazine* in 1787, t. 44, and it has come down little altered to our own day. In 1875 Boissier describes it as "forma hortensis a me nunquam spontanea visa." It still exists in cultivation, and is the (old) "crimson and white" of Messrs. Sutton. It seems always to have been popular in cultivation on account of its agreeable fragrance. This confirms the Syrian origin of the original stock, for a white-flowered form "is found in Palestine which is very fragrant."*

* *Le Souvenir Horticole*, 1867, p. 25.

* *Royal Horticultural Society Journal*, N. S., vol. 12, p. 16c.

* *Annot. Bot. Hort. Soc. Lond.*, vol. 2, p. 212.

I was unable to obtain from Mr. Martiu any explanation of how this particular variation had come about, but he informed me that it had been of frequent occurrence. Spreading flowers had always been destroyed as departing from a desirable type. More recently, on account of their Orchid-like habit, they had taken the popular fancy, and had been preserved.

Doubling.—Even in the wild type there is a tendency to a slight multiplication of the corolla segments. Mr. Martiu has worked upon this, and has produced flowers [semi-double]. He seems to think that there is no limit to which this multiplication cannot be carried practically, and hopes in time to produce "mop-headed" flowers like a *Chrysanthemum*. The so-called doubling of flowers, as in the Rose, is a teratological phenomenon, and is due to the conversion of stamens into petals. But in *Cyclamen* this is not the case. The stamens, which are normally equal in number to the corolla segments, are also multiplied. Although a quinary symmetry is general in the Primulaceae, *Trientalis*, a near ally of *Cyclamen*, ordinarily exhibits a considerable range in the number of parts of the flower. Here again *Cyclamen*, under artificial conditions, shows a reversion to a more general type.

(To be continued.)

NOTES FOR AMATEURS.

INDOOR PLANTS.—Under this title, I wish to speak especially to those who have not even a veranda or cold frame, and are obliged to grow their few flowers in the parlour or office. How many are disappointed after buying a fine *Palm* or variegated *Aspidistra*, to find that it soon slowly dies, and its beautiful colours fade away. This gradual dwindling is principally owing to the conditions under which the plant grew before it was brought into the house. It was assuredly developed rapidly in a high temperature, with abundant moisture; and then found itself suddenly deprived of elements which influenced its life and growth, so grew yellow, dropped its leaves, and at last died.

When seeking an indoor plant, it is well to get it direct from the florist, choosing it not from a hot-house, but from a greenhouse, wherein the temperature more closely approximates with that to which it will afterwards be subjected. It is not wise to select from plants grown for market, as these are usually raised in quantities, or are unduly forced with heat, and manure, being suitable as temporary decorations but not for permanent indoor plants. The grower is not concerned if a plant, when once sold, lives but a month afterwards.

The flower-lover should select a dwarf specimen, free from defects and blemishes, rejecting "drawn" plants with over long and weak stems. What is the right course to pursue with indoor plants? What care do they need? Should they be re-potted or manured to make them do well? No; the plant should be kept just as it is when it comes from the florist's greenhouse.

It should neither be forced nor retarded, as for one perfectly-grown plant you had many poor, weakly, and stunted. The first consideration is usually what quantity of water to give each week. The watering of indoor plants is a difficult question, requiring much care, as on it the life and beauty of the plant depend. Usually the air of living-rooms is dry and warm, and much of the water given is absorbed by the surrounding air; also, there may be a fire burning. The drainage of the flower-pots may or may not be efficient. The earth also may be porous or heavy, compact, and scarcely permeable. The rule is to water plants when they are thirsty. Partial watering is to be avoided, as the upper part alone is wetted, the soil appears moist, but below where are the roots, is dry, sometimes in a sandy state, which it is impossible to moisten. The plant will suffer less from lack of water than from a continual excess of dampness. If too dry, its whole appearance shows it, it lacks vitality, but the would-be gardener knows the remedy, most plants (*Ferus* excepted) regaining their natural condition after copious watering. With excess of water the roots rot, the soil becomes sour, and the whole thing a mass of mud, the plant certainly dying unless returned to the florist to be started again.

It is a mistake to remove the drainage from the bottom of a pot; the more perfectly the stones act, the better will the roots thrive.

Beside such indoor plants as *Chamærops excelsa*, *Aspidistra lurida* and the variegated variety, *Grevillea robusta*, *Phoënix reclinata*, and *Aralia Sieboldii*, there is one good greenhouse plant with fine foliage, which is very rarely seen, in spite of its hardness and endurance. This is *Lomatia ferruginea*, which may be compared to *heterophylla* (*Sisifolia*), with dentate foliage, very sturdy for indoor cultivation. *Louis Gentil, Kew.*

THE WEEK'S WORK.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Bedford, Dorking.

Cattleya Luddemanniana (*speciosissima*) and its several varieties, are essentially late summer-flowering plants, but being a comparatively shy species to bloom, it is frequently disappointing to the cultivator. No difficulty is experienced in getting the plant to grow freely, but when treated as are other *Cattleyas*, it seldom shows any inclination to flower, and although the leaves and pseudo-bulbs produced under such conditions are large, they are not of a sturdy character. After being rested during the past winter months, the plants will now be making numerous roots at the base of the last made pseudo-bulb, and this is the best time to repot the plants or afford them some fresh rooting material. Shallow pans with perforations around their sides are preferable, as they afford a convenient means of suspending the plants from the roof. Afford liberal draughts, as this species may give water more frequently during its growing season than most *Cattleyas*. The compost should consist of equal parts of peat and sphagnum-moss. Pull the peat in pieces, and sift out the greater part of the dust through a coarse meshed sieve, cut up the moss roughly, then mix the two ingredients well together, and work in with it a few clean crocks. Suspend the plants in the Mexican or *Dendrobium*-house, where they will obtain plenty of air and direct sunlight. *C. Luddemanniana* produces its flower-spikes on the completion of its growth; and if no spikes appear at that stage, the plants should be subjected to the ordinary resting system.

Cattleya Edouardo and its varieties, *splendens*, *crocata*, and *Walsleyi*, bloom during the months of July and August, a period when other *Cattleya* flowers are scarce. Like the preceding species, the flower-spikes come up together with the new growth, and push up out of the sheaths just before the pseudo-bulbs are made up. The blooms, when open, have a delicious fragrance, and if placed in a dry atmosphere, they will last in beauty for several weeks. At the present time the plants are starting into growth, and should be placed in the East Indian-house, or an ordinary plant-stove, and they will need to be shaded from strong sunshine. During the earlier stages of growth, afford just sufficient water to prevent the compost from becoming dry; any excess at the root at this time frequently causing the young growths to turn black and decay. When the flower-sheaths are seen pushing up, afford water more freely, but the quantity should be diminished gradually after the first blooms open, and only enough being given to prevent the stems and leaves from shrivelling. Re-potting is best done immediately after the flowers fade.

Laelia rubescens (*acuminata*) and *L. Gouldiana* being now at rest, should be placed where a little more warmth exists than that of an ordinary greenhouse, but with more air and less atmospheric moisture than is given to any *Orchid*-house, very little water being needed at the root to keep the pseudo-bulb plump; and even if they are allowed to shrivel slightly, it will do no harm.

Cryptopodiums.—Such large and distinct looking *Orchids* as *C. Andersonianum*, *C. Sanderianum*, *C. punctatum*, *C. Ericssonii*, *C. macranthum*, and *C. suraviense*, are deserving of extended culture, their tall branching spikes producing numerous showy flowers, which open continuously for several weeks in succession. These species are now commencing to grow, and if necessary, they may be repotted, but plants that are showing their flower-spikes should not be disturbed until the spikes are cut. Use fibrous loam and coarse sand split in equal parts, to which may be added some leaf-soil and sphagnum-moss. As the drainage must be provided, and being best-loving plants, they should be placed in the highest available temperature, and where they may obtain plenty of sunlight at all times. When the growths are completed, the plants should be placed in a warm sunny greenhouse, so that the pseudo-bulbs may become thoroughly ripened.

Dendrobiums.—*D. cymbioides* now commencing growth may be repotted or top-dressed. Cultivate the plant in a shallow pan, and suspend it close to the roof-glass in the *Cattleya*-house. *D. Benonis* is fast pushing forth both young growths and flower buds from the last-made pseudo-bulbs, but the grower should not be tempted to afford the plant water until after the flowers fade, as the young growths are liable to damp off from over wetness. The same remarks are also applicable to plants of *Dendrobium trapezium*, *D. crystallinum*, *D. tortile*, *D. amicum*, *D. aqueum*, *D. Dalhousieanum*, *D. Parishii*, and its varieties.

Platycolepis filiformis is generally grown to great heat, so becoming a prey to red-spider. Although it is a native of the Philippine Islands, the atmosphere of the East Indian-house appears unventilated to it. The intermediate or shady house of the *Cattleya*-house is the best place for it at all seasons. Suspend the plants close to the roof glass, but out of the course of the currents of dry air from the top ventilators. On clear and bright mornings it is good practice to take the plant down and slightly bedew the grassy foliage over with tepid rain-water. The plants are now starting to grow and throw up flower-spikes in conjunction with the young breaks; and from this time until the growths are fully completed, abundance of water at the root and in the atmosphere is necessary. Repotting is best deferred until after the flowers have faded. *P. glauca* must be afforded plenty of water now to assist the proper development of the current season's growth.

THE FLOWER GARDEN.

By CHARLES HERRIN, Gardener, Droppora, Maidenhead.

Ornamental Plants intended for damp situations in the pleasure-grounds or on the wild garden, may be very freely planted out early this month: clumps of Bamboo and similar plants from the open may be safely transplanted. In sheltered dells, or upon the margins of lakes and by the side of streams, Bamboos in variety are appropriate subjects. The soil best suited for hardy Bamboos is that of a rather heavy nature, and one capable of retaining moisture, although stagnant water about the roots should be guarded against, and where likely to be too wet slightly raised mounds should be thrown up on which to plant them. The following are some of the hardiest and most handsome that I have planted out early this month: *Arundinaria japonica* (*Bambusa Metake*) is a good grower and hardy, although it does not form so handsome a bush as some other species. *A. Simoni* is a strong and erect grower, established clumps growing to a height of 10 feet to 15 feet. *A. nitida*, a species with bright green foliage and very hardy, grows to a height of about 10 feet. Other handsome species are *Phyllostachys Henonis*, *P. flexuosa*, *P. nigra*, *P. aurea*, *P. nitida*, a tall and erect-growing Bamboo, and *P. viridis glaucescens*, a tall free-growing one, and one of the best for general planting. *Bambusa palmata* dwarfs in growth than most of the preceding, is distinguished by its broad and Palm-like foliage. Other plants suitable for these situations are *Rodgersia podophylla*, *Herculeum giganteum*, the giant *Croc Pansip*; *Arundo conspicua*, *Glycerium argenteum* (*Pampas-grass*), and *Elymus glaucifolius*.

Roses.—The cold nights, accompanied with north-east winds, have prevented free growth in *Roses* on walls, and when thus stunted the shoots are more liable to the attacks of green-fly. If this is already in evidence, the tree should be well syringed with some approved insecticide—such as Bentley's *Quassia extract*. This remedy being prepared in a concentrated form, can be readily used by simply mixing it with the desired quantity of clean cold water, and for syringing *Roses* and other subjects infested with green or black aphid, it is a cheap and effectual insecticide.

General Work.—This is a busy time in the flower-garden department. Propagating of such subjects as *Heliotrope*, *Ageratum*, *Nasturtium*, *Coleus*, and others that form roots quickly may still be practised in any hot moist house or frame. *Alternantheras* should be dibbled in thickly in frames on a hotbed and a little light soil, where, if kept close, they will strike in a few days, and the tops may be taken off in a week or ten days later to be struck in a similar way. The gradual hardening off of bedding-plants generally must reach the advanced stage, as the time for putting these out into the beds is now approaching. The inclement weather by day, and the frosty nights, have necessitated considerable care, and no tender plants should be left exposed at present, especially when coming fresh from under glass. Annuals sown in frames or small

boxes should not be allowed to become matted together and drawn up, but be pricked off singly before over-rowing takes place. Early-sown Carnations should now be ready for planting into the borders, and seeds may yet be sown for a late supply of plants. Border Crysanthemums may also be planted out, and if they have been previously hardened off properly, a slight frost will not injure them.

THE KITCHEN GARDEN.

By W. POPE, Gardener, Highclere Castle, Newbury.

Potatoes.—The early crops in pits and frames will now be nearly over, and any that remain and are matured sufficiently may be lifted, and stored in a cool, dark shed, until required for use: the frames may then be utilised for Cucumbers, Melons, or Dwarf French Beans, which, if sown now under glass, will come into bearing some time before those already planted outside. Ashleaf, and other early sorts of Potatoes now showing through the soil, should be hoed through to check seedling weeds, and loosen the soil, preparatory to earthing up the crop, which should be done when the plants are about 6 inches high. Any artificial manure it is intended to apply to these is best put on before the first hoeing, scattering a handful or so round each plant, according to strength of the manure. In the case of sharp frosts, sometimes experienced during the thick sowing, May, protection of some sort should be afforded, such as a doubled terranet, stretched over, but clear of the tops.

Chicory.—A few rows of the improved form of Chicory, known as Winton, should now be sown. If this be done too early in the season, flower stems are thrown up in the autumn, but at this season it is quite safe to sow. Any fairly rich soil is suitable, provided it be not shaded by trees. The rows may be 15 inches apart, thinning early to 6 inches from plant to plant.

Endive.—If Endive is likely to be required early in the autumn, a pinch of seed should now be sown very thinly in shallow drills; and when large enough, transplant the seedlings carefully on to rich soil, in an open situation, at 9 inches to 1 foot apart each way. The Round leaved Batavian is the most useful, though by some the Moss-curd is preferred.

Pickling Onions.—To obtain small Onions for pickling and other purposes, sow a small quantity of seed now on land that has been made thoroughly firm by treading. The seed may be sown broadcast, and rather thickly, covering them with half an inch of soil, after which roll or beat down firmly. The Silver skin and the Queen are the best varieties. Thinnings from the main bed also form useful bulbs for this purpose if dibbled in thickly together in poor soil.

Kidney Beans.—A good sowing of these may now be safely made in the open, the increasing warmth in the soil being conducive to the germination of the seed. Plants from this sowing will be quite safe from the late spring frosts. Any that may be showing through the soil must be given some kind of protection in all except the most favoured localities. As a guard against cold winds, a few leafy twigs, stuck along one or both sides of the rows, will be of service. Plants raised under glass for planting out, must be kept fully supplied with air, tying each to a stake as growth advances, and shifting them into pots a size larger if likely to become pot bound. A good breadth of Canadian Wonder may be got in where Runners are appreciated, or in places where Runners may not succeed. In such cases, the Climbing French Bean may be recommended, not being a tall grower, and as affording a longer succession of large handsome pods of the same type as the dwarfs.

FROITS UNDER GLASS.

By F. HARMS, Gardener, Easton Castle, Ledbury.

Succession Pines.—These plants, having now a good root-hold in the new soil after re-potting, and being in active growth, should, in order to ensure robust and sturdy growth, have every attention in regard to airing and affording water at this stage, for giving first-class fruit, no after-indeals of cultivation remedying spindling of the leaves. Never allow the plants to get very dry at the roots, or premature fruiting may occur; on the other hand, a very moist state of the soil must be avoided, the main point in their culture being plants furnished with large quantities of healthy roots. The time at which the house is closed should be made later by a few minutes each week; the ventilation must also be increased, and a moister state of the air maintained by sprinkling the paths, &c., the plants being bedewed at closing time if the day has been very hot. In some sunny parts of the country a slight amount of shade in the middle hours of the day is necessary.

Suckers.—These, if now making growth fast, must be afforded ample space for the due development of the leaves, or drawing will take place, and be afforded more water at the root, the small amount of soil in the pots soon drying up in hot weather. If the stock of suckers is less than the requirements of the place, and strong suckers are available, a few may be detached from the parent-plants, and potted.

The Early Peach-house.—The fruits will now be approaching ripeness, and if lime exists in the water syringing with it must be discontinued; but if clean rain-water be available it may be used, placing it in the house a few hours before using. Let all the leaves be drawn aside from the fruit, or removed where shading it unduly, for often a single leaf will spoil the otherwise fine colour of the fruit. Keep laterals pinched at a joint or two. Ascertain if the border is sufficiently moist, and should it be getting dry, afford water abundantly, which will suffice till the crop is gathered. On warm, sunny days afford air abundantly, especially if the houses are flat-roofed; for unless this matter be closely attended to, the fruit will be apt to get scalded on the sunny side. To prevent this, where the lights are movable, pull down each alternate light so as to let the air into the middle of the house. In houses of this sort, the thermometer is not a very trustworthy guide on a hot day, as it will probably hang below the trees. To pass the hand through the trees, and between it and the glass is a better test, as the warmth there felt will be very different from that indicated by the thermometer.

PLANTS UNDER GLASS

By G. H. MAXCROCK, Gardener, Luton Hoo Park, Luton.

Adaptions for Winter-flowering.—Plants which were struck from cuttings in the autumn will now be so well rooted as to require potting in their flowering-pots. For these compost should be used of equal parts loam, peat, and leaf-mould, with sharp sand in liberal quantity, and small quantity of small lumps of charcoal. If the flower-house is small one, pots 8 inches in diameter, will be a suitable size. The potting soil should be placed round the ball firmly, and to do this a wooden rammer should be used, the soil being merely made somewhat compact, but not rendered impervious to water, as some beginners are inclined to make it. The plants being re-potted, remove to a warm house, and keep them well syringed; and about the end of June place in a deepish hot garden-frame, plunging the pots to the rim in tan, coal-ashes, &c. During the autumn the lights may be drawn off altogether, in order to mature the wood, and prevent over-luxuriant growth; and it being essential that the wood be well ripened to have plenty of flower in the winter, the plants must have a sunny position. The plants require stopping twice or thrice whilst making rapid growth. For furnishing large greenhouses and conservatories, older plants will be found better than young ones; and, assuming these were pruned to hard back in the spring, growth will now be progressing. These larger specimens do well if they are planted out in the open ground when all danger of frost is past, that is about the first week in June. In order to obtain good growth, trenches may be made as for Celery, in the sunniest part of the garden, and in these place some of the soil of which the ingredients are given above. The plants should be set out at 3 feet apart, and afforded some slight protection against the wind for about a week. Let the plants be well syringed in fine weather, and supplied with water to the roots in dry getting dry. Under a sort of treatment, the plants will grow to a large size by the middle of the month of September. At that date a bright spade should be pushed down round each, so as to prepare them for lifting and potting about the end of the month, or sooner should the weather become cold, and if the plants be afterwards well shaded for a week or two, and the lifting has been carefully done, very few leaves will be lost, or the plants suffer in any way. Abutilon Boule de Neige is one of the best for winter-flowering, Canary Bird and Yellow Princes are also fine varieties.

Half-rooted Plants.—These plants of whatever genus, as not be allowed to suffer through inattention at this season, and the small plants in pots which will flower in the autumn and early winter months, should be potted and tied-out, and afforded ample space to grow, otherwise the lower branches will be much weakened or killed. Plants of large size should be turned round, at the least twice a week. In the case of Ericas, a watch must be kept for mildew, which if found to be present must be dressed with flowers-of-sulphur, first spraying the plants with a fine-rose water can, to make the sulphur adhere.

In twenty-four hours the sulphur should be removed by the syringe, laying the plants on their sides, to prevent it being washed into the soil. Red-spider soon spoils *Ficus*, often before it is detected, and a close examination of these plants should be made at short intervals of time. Fresh air should be admitted in increasing volume, and in all cases the plants should be thoroughly moistened at the roots when water is needed. Correas and *Eriostemons* should be well syringed, and in general treated similarly to *Boronia*, *Trochæas*, &c.

Greenhouse Climbers.—The shoots of all climbers should be carefully trained, and the growth of old-established plants assisted with weak liquid-manure. *Lagerfloras* should, as regards the young growing shoots, springing up from the roots, be kept free of slugs, either by dusting with Tobacco-powder, or protecting the young growths by means of cotton-wool, using the fluffy parts of it round each growth; a search should also be made every night for them. Syringe the foliage daily with rain-water, and fumigate the plants, to make sure that no thrips harbour on them.

THE HARDY FRUIT GARDEN.

By H. W. WARD, Rayleigh, Essex.

Thinning-out the Fruits on Peach Trees.—Healthy, fruitful trees invariably set heavy crops of fruits if the blossoms are protected from the frost, and severe thinning of the fruits becomes necessary. A knowledge of the size to which the fruits of the several varieties attain under good cultivation is desirable in the part of those entrusted with the operation. Fruits of such varieties as Alexander, Waterloo, June Amislen, Hale's Early, Stirling Castle, and Belle-garde, being of medium size, may be left a couple of inches closer on the trees, say, 10 inches apart at the time of thinning, than fruits of Royal George, Violet le Néige, Prince of Wales, Chancellor, and Teton de Venus; whilst such large-growing varieties as Barrington, Golden Eagle, Exquisite, Princess of Wales, Late Admirable, Sea Eagle, and Salway should be afforded still more space on the trees. Therefore, thin out fruits upon the varieties indicated to 5 inches, 6 inches, and 7 inches apart, according to size, reducing the numbers by one-half a few weeks later, leaving, as a matter of course, the most even-sized and best-placed fruits to form the crop on each tree. The fruits left should be 2 or 3 inches clear of the nails (where nails and shreds are employed to secure the trees in position on the wall), in order that the individual fruits can obtain to full dimensions without coming in contact with them. Much injury is caused through insufficient space being allowed for the fruits to swell to full size without touching the nails.

Protecting Strawberry Flowers.—Garden netting, which is used to preserve ripe Strawberries and other fruits from the ravages of birds, may be applied with advantage to preserve the open blossoms from the effects of late frosts. Place a few forked sticks into the ground at short intervals in breadths of Strawberry plants to be thus protected, so as to keep the netting clear of the blossoms. If the netting be doubled or trebled in thickness, it will necessarily be more effective. A thin covering of straw would also have the desired effect.

Watering.—Owing to the dry winds which have prevailed during the last few weeks, surface-rooting fruit plants like Strawberries and Raspberries, which are growing in light and perhaps shallow soils, should be well watered at sufficiently short intervals to maintain the ground about the roots in a moist condition. Wall-trees occupying south-west and east aspects should also be given attention in this direction.

VALUING NURSERY STOCK.

In the article by Mr. Freeman, Q.C., on "The Humours of Arbitration," in the first number of the *Laud Magazine*, there is a story of a counsel who was examining a nervous expert in the valuation of nursery stock. The witness was hostile, and counsel took him through the list thus: "What do you put down for the *Platanus Marisii*?" He did not know. "Really? Well, what for the *Eucalyptus* reuber, the *Leptosiphon androsceus*, or the *Echeveria secunda glauca*?" Still no answer. Counsel went on: "I'm afraid you're not much used to valuing plants! At least you know the *Lophospermum scaberrimum*?" "No." "Nor the *Matricaria eximia corymbosa*?" "No." "Well, what do you know? Do you know a *Cabbage*?" Witness (in despair): "Yes, thoroughly." Counsel: "So I thought!" At this point the jury indicated that they were thoroughly satisfied about the claim.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the **PUBLISHER**. Letters for Publication, as well as specimens and plants for naming, should be addressed to the **EDITOR, 41, Wellington Street, Covent Garden, London**. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction in these pages, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturalists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY,	MAY 18	{ Somerset County Agricultural Show, at Minehead (2 days).
WEDNESDAY,	MAY 19	{ Royal Botanic Society, Summer Exhibition at Regent's Park.
FRIDAY,	MAY 21	{ Royal Botanic Society, Lecture.

SALES.

WEDNESDAY,	MAY 19	{ Japanese Lilies, Carnations, Greenhouse Plants, Gadholi, &c., at Protheroe & Morris' Rooms.
FRIDAY,	MAY 21	{ Imported and Established Orchids, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chislewick.—55.4°.

ACTUAL TEMPERATURES:—

LONDON.—May 12: Max., 49°; Min., 37°.
 PROVINCES.—May 12 (6 P.M.): Max., 50°; Valencia; Min., 36°; Sumburgh Head.

The Consular report for the past year on dairy and vegetable farming in the district in France of which Cherbourg may be taken as the centre, and drawn up by Mr. M. C. GURNEY, the present consul, seems to be exciting a good deal of attention in this country, and with much reason. In showing how great is the success of the French dairy farmer and market gardener, the consul reads the English and Irish farmer a lesson, which we, in our monthly stock-taking paragraph endeavour to enforce. Now and again we tell of enormous imports of dairy-farm stock. Mr. GURNEY, in the report for 1896-7 tells the full tale, for which we have no space here, but which the Board of Agriculture would do well to curtail and scatter broadcast over the length and breadth of the land. This we say advisedly—having the idea that only in this way can the most be made of the valuable services of such a man as Mr. GURNEY. The full report can be had from Messrs. EYRE & SPOTTISWOODE, East Harding Street, London, E.C., for the low price of 2½d. One or two extracts on subjects akin to our programme may be permitted here. The first is connected with fruit gardens, &c.:—

'The mild climate of La Manche has enabled nursery gardeners to thrive.

Fruit (Pears, Apples, and Strawberries) is exported from this consular district. Cider Apples go in large quantities to South Germany for the German bottle cider trade 'Apfelwein.' Thus French Apple-juce finds its way to England, America, and even Australia, *via* Germany. Could not some of this trade be diverted to the south-west counties of England? Do our farmers in this also need teach-

ing? This district has a special school where instruction in cider-Apple growing and cider making is given.

I know of an English nursery gardener who annually tours through my district, and comfortably picks up all the young shrubs and plants he requires at very low cost and with very little trouble, owing to his perfect knowledge of the French language and commercial methods. This enterprising Englishman is, indeed, a remarkable exception.

It may be asked why does he come to France to stock the shrubberies and parks of our homes in England. Because labour is cheaper and prices are absurdly low, and the profits he makes more than cover the outlay on his annual trip across the Channel, combining in his case, pleasure with profit. If the home supply is insufficient could not the demand be supplied in our southern home counties?

Even Mistletoe by the 100 crates goes to England at Christmas time from Cherbourg and Granville.

This consular report is of general interest, an excellent sample connected with Potatoes, &c., may be cited as proof:—

'Potatoes of the earlier sorts sold well, and made money for growers, the exporting season lasting over two months. Prices for kidneys averaged about 12 fr., and for rounds 6 fr. The Myatt's being somewhat of a failure owing to drought, the Flukes and Royals yielded the bulk of the crop. Any increase or deficiency in this crop from year to year does not point to the falling-off of the cultivation, but simply to the fact that the weather has been unfavourable to the crop.

On the contrary, the cultivation has gained ground, and is likely to continue to do so, for the farmer in this district has copied the Jerseyman, and now sees the wisdom of growing Potatoes for the requirements of the English market. There are, however, many places to which this culture may extend, in spite of the distance the farmers have to cart.

Some of the earliest came from near, or towards, Cayeux, and it seems strange that no enterprising shipowner has started a steamer for this trade during the Potato season. A vessel of light draft and sufficient horse-power would certainly pay, in spite of the entry to Cancale being a little difficult at some tides, if the business were carried out in conjunction with a firm here, who would collect the produce. The first consignment of Potatoes for England left here, *via* Southampton, on April 29, 1896.

There has now been formed at St. Malo a syndicate for the purpose of opening a regular market-plate for the Potato trade, where merchants will buy the produce instead of, as hitherto, all having different stations on the various roads leading to St. Malo-St. Servan.

In this report Cauliflowers are included, the cultivation of which, as a second crop, after Potatoes, &c., has been very successful for the last two seasons, selling at prices varying from 40 fr. to 12 fr. per 100 heads. The largest are preferred in Paris, but the medium-sized heads go to England. The railway tariff has been reduced so as to put St. Malo on the same footing as Roscoff, in Finistère, for many years producing this vegetable. This culture is capable of large development.

Pigs are almost all exported to the Channel Islands, though a few go to England when pork is cheap. This year it has fallen to 40 fr. per 100 lb., a serious matter for farmers. Small pigs sold for little or nothing during 1896."

It may be added that Mr. GURNEY invites communication by letter from all who desire to have further instruction in the various subjects reported upon by this excellent public servant.

A Vanished Lily.

CONSIDERING the beauty and variety of newly introduced Lilies now in cultivation, it is not surprising that a comparatively unattractive and critical species, should have been lost sight of, though it may still exist in some

old gardens. We allude to *L. peregrinum*, Mill., which Count SOLMS-LAIBACH has lately rescued from oblivion.

This Lily was introduced into northern Europe early in the last quarter of the sixteenth century, and it is described and figured by a number of authors of that period. It is included in GERARD'S *Catalogus Horti*, &c. (1596), under the name *Lilium album bizantinum*; and in the first edition of his *Herbal* (1597), p. 146, it is figured side by side with *L. candidum*. Concerning these two Lilies GERARD says:—

'The White Lily of Constantinople hath very large and fat leaves, like the former, but narrower and lesser. The stalk riseth up to the height of three cubits, set and garished with leaves, also like the precedent, but much lesser. Which stalks oftentimes doth alter and degenerate from his natural roundness to a flat forme as it were, a lath of wood furrowed or chanelled amongst the same as it were ribbes or welts. The flowers growe at the top like the former, saving that the leaves doe turne themselves more backward like the Turke's Cap, and beareth many more flowers than our English white Lillie doth. Our English white Lillie groweth in most gardens of England. The other groweth naturally in Constantinople and the parts adjacent, from whence we had plants for our English gardens, where they flourish as in their owne country."

He further gives the distinguishing characters of the two species as we have quoted them, the description being further worthy of note as descriptive of a fasciated stem. Fasciated stems are common in Lilies, and they were observed by our forefathers, for at p. 151 of GERARD'S *Herbal* is a woodcut of "The great mountaine Lilly, showing such a 'stalk' which has turned from his roundness into a flat forme," as those of the white Lily of Constantinople."

Count SOLMS has investigated the history of *L. peregrinum*, and, with one or two exceptions, which Mr. HEMSLEY points out, his account is complete and accurate. CLUSTIUS, *Stirpes Pannonie* (1583), p. 137, gave an account of it, under the name of Sultan Zambach, which he reproduced in his *Kariorum Plantarum Historia* (1601), p. 135, together with a figure. In the meantime, LOBELIUS, *Plantarum seu Stirpium Icones* (1581), had published the very same figure, which figure, according to Count SOLMS, was really prepared for the *Stirpes Pannonie* of CLUSTIUS (1583); but in the Kew copy of this work there is, as Mr. HEMSLEY tells us, no figure of *L. peregrinum*. On the other hand, Count SOLMS has overlooked the fact that GERARD published a figure of it in 1597. This figure is not from the same block as that of CLUSTIUS and LOBELIUS; yet it is evidently a close copy. Respecting the present rarity of *L. peregrinum* in gardens, Count SOLMS states that the well-known Lily-grower, Mr. MAX LEICHTLIN informed him that he had never seen it. But there is some mistake or lapse of memory here, because, says Mr. HEMSLEY, there is an excellent cultivated specimen in the Kew herbarium received from Mr. MAX LEICHTLIN in June, 1875.

With regard to its claims to specific rank, opinions have differed. LINNEUS, *Species Plantarum* (1753), p. 302, makes it a variety of *L. candidum*, floribus dependentibus; whilst PHILIP MILLER, who knew it well in cultivation, maintained that it was a distinct species. In the first edition of his *Gardeners' Dictionary* (1731), he says: "It is now become almost as

* Eine fast verschollene weisse Lilie. *Botanische Zeitung*, 1897, pp. 63-79.

FIG. 110.—COTTAGE LILY (LILY) IN MR. E. H. ADAMS'S GARDEN. (SAY & CO.)

plenty as the common White Lily in many gardens." In the eighth edition (1768), where he first adopts the bi-nominal nomenclature, he states that it is undoubtedly a distinct species, differing from *L. candidum* in its slenderer stem, fewer narrower leaves, somewhat smaller, drooping flowers, having the petals more contracted at the base. Many authors, including ELWES and BAKER in this country, follow LINNÆUS; but, whatever rank it should take, there is no difficulty in distinguishing it. Perhaps some readers of the *Gardeners' Chronicle* may be able to give its recent history in this country.

It may be added, that the native country of the common white Lily was not known till comparatively recently, the Greek localities cited by BOISSIER being all cultivated spots. On the mountains of Lebanon, however, it occurs in a truly wild state.

CYPRIPEDIUM BELLATULUM.—This, the most ornate of the section commencing with *C. niveum*, and continuing through *C. Godefroye* and its varieties, which merge into *C. bellatulum*, is always an object of admiration when it produces its quaintly-formed and finely-coloured flowers among its scarcely less beautiful leaves; but seldom does it attain such perfection as that of the fine specimen which gave material for our supplementary illustration, and which flowered some time ago with E. H. ADOCK, Esq., of Ribblesdale, Dorking, an amateur who is specially successful with this class of *Cypripediums*, though it frequently proves intractable in some gardens. Various are the essentials prescribed for its easy culture—such as sandstone, or pieces of chalk mixed with the potting material—but practice proves in this case, as with many other reputedly difficult Orchids, that if a suitable position in a tolerably warm and moist house be found, they thrive without special treatment.

KEW: OLD CATALOGUES WANTED.—The Director of the Royal Gardens, Kew, would be obliged to readers of the *Gardeners' Chronicle* for assistance in completing sets of the descriptive Catalogues of Messrs. SANDER, St. Albans, and L'HORTICULTURE INTERNATIONALE, Société Anonyme, Brussels, for the library. Of the former all previous to 1891 are wanting, and of the latter those for 1892 and 1893.

THE CHISWICK GARDENS of the Royal Horticultural Society at the present time have a very satisfactory appearance. They are clean and tidy; most of the ground has been planted with one crop or another, and the rest is in a prepared state for later sowings. Many of the Fellows have not visited Chiswick since the last exhibition there, and since then very considerable alterations and improvements have been accomplished, which will undoubtedly have the effect of increasing the usefulness of the gardens, as well as being conducive to a convenient arrangement of the fruit-trees, and the orderly aspect of the gardens generally. It is gratifying to observe that as much of the space as possible is being given during the present year to trials of various descriptions. Thus, the trials of new and alleged superior varieties of culinary Peas occupy a considerable space, there being a row each of the varieties which, we believe, number considerably over six. Attention is also being given to the Potato, and many varieties will be tested side by side during the present season. In another part of the gardens, a few new varieties of Strawberries will prove their value in comparison with the best existing kinds; and later on, there will be extensive trials of annals. We say extensive advisedly, for of Asters alone there are entered upwards of 100, though many of these will doubtless prove to be synonymous. The group of old fruit-trees that was known as "Rivers' garden" has been sacrificed, and the south-east wall which faces the spot, and was covered by old and comparatively worthless Pear trees, now supports a number

of cordou trees representing the finest varieties in commerce. Since the Plum trees in the garlick have all been transplanted into one piece of ground and arranged alphabetically, they are likely to be of increasing value for reference, as it will be a very easy matter to find a particular tree. Mr. WRIGHT intends to overhaul the small circular rockery in the near future, and take means to prevent the stronger-growing species from absorbing more than their share of the available space. Several rare species of Prunella have been planted there, presents from Sir J. T. D. LLEWELLYNS, Bart. It is depressing to note the wholesale manner in which the fruit-buds have fallen from the Pear trees. From the exceptionally ungenial weather or other cause, many of the trees appear to be casting five-sixths of their buds, and the promise for Pears is bad. The usual exception, however, is to be seen in the case of Louise Bonne of Jersey upon one of the walls. These trees have set an uncommonly large number of fruits. Of Apples, the promise is better, and indeed very good. The Peach and Nectarine trees on the south wall have set excellent crops of fruits. The Vines in the large vineery are looking very well, and promise to give a good crop of medium-sized bunches of good Grapes; in the Muscat-house there is an excellent promise of an even and heavy crop. The very pretty standard Peach trees of moderate size in one of the houses are carrying a very satisfactory crop, and look most healthy. In one of the smaller houses is a collection of plants of the variety of Tomato raised at Chiswick last year, and known as Chiswick Red, from a cross between Comet and Peach. It was thought from the one plant that fruited last season to be a first-rate sort, and the plants are being grown to furnish seeds for distribution to the Fellows. Altogether, there is much credit due to Mr. WRIGHT and his staff for the present appearance of the gardens. The new house at the entrance is furnished with Camellias and other plants, and at present are but partially established.

"AIDE MEMOIRE DE BOTANIQUE CRYPTO-GAMIQUE," par HENRI GHARD (Paris, J. E. BAILLIÈRE ET FILS).—This *Manuel d'Histoire Naturelle* is one of a series devoted to different branches of botanical and zoological lore. All these books are similar in aim, which is to present students with all the information possible in as small a space as possible. By mastering the epitomised and condensed botanical instructions herein contained, a superficial knowledge would be gained; but for those who prefer to work more slowly and thoroughly, a larger volume should accompany the smaller one.

"BOTANICAL MAGAZINE."—The May number contains coloured figures and descriptions of the following plants:—

Ayax kewensis Jacobi, t. 7532.—This is the finest and largest species known, and was recognised as new by General JACOBI at Kew in 1865. It did not flower till 1895, when it produced a panicle in the way of *A. americana*. The plant did not seed, and died after flowering, not before a number of bulbils were produced from the peduncle, so that it is hoped that a number of young plants may soon be distributed.

Mardilaria Houtteana, Reichb. f., t. 7533.—A species with an ascending rhizome, bearing elongated ribbed pseudo-bulbs, linear lanceolate leaves, and long-stalked starchy flowers, about 1½ inch broad, with ovate oblong neutre segments, yellow externally, brownish-orange within.

Syringa amurensis, Ruprecht, t. 7534. A small tree, with all the appearance of a Privet, even to the flowers, but the fruit is not a burry, but a capsule, as in *Syringa*. It is a native of Japan and North China. It is a very handsome hardy flowering tree.

Vimorphobolus Ecklonii, D. C., t. 7535.—A sulfureous Composite, with obovate, oblong, sparsely-toothed leaves. The flower-heads are solitary at the ends of the stalks, each measures about 2 inches across, the ligules being spreading, of a violet colour beneath, white above, disc purplish. It was grown at Kew as a summer bedding plant.

Gomphocarpus setosus, R. Br., t. 7536.—A South Arabian Asclepiad, with shortly-stalked linear leaves, and pendulous umbels of small greenish flowers, with the peculiar structure of Asclepiads, but destitute of the born-like processes which emerge from the cup-shaped bodies which constitute the corona. Kew.

ROSE SHOW FIXTURES FOR 1897.—June 7 (Monday), Cambridge; 9 (Wednesday), Chelmsford; 15 (Tuesday), Ryde; 23 (Wednesday), Richmond, Surrey; 25 (Friday), Maidstone; 26 (Saturday), Dorking; 29 (Tuesday), Hereford; 30 (Wednesday), Ealing and Reading; July 7 (Wednesday), Hanley (two days), Leeds (three days); 8 (Thursday), Newcastle-on-Tyne (three days); 13 (Tuesday), Wolverhampton (three days); 17 (Saturday), New Brighton; 28 (Wednesday), Chester (two days). The above, together with those given in the *Gardeners' Chronicle* on March 20 and April 10, writes Mr. MAWLEY, are the only dates that have as yet reached him. He will be glad to receive any further fixtures as early as possible at "Rosebank," Berkhamsted, Herts.

NURSERY AND SEEDSMEN'S CRICKET.—We have received from Messrs. SUTTON & SONS, seed merchants, Reading, a list of fixtures for cricket matches taking place in the period between May 19 and August 23 of the present year, in which the A, B, and junior teams will play with a number of local and other south country clubs. There are in all forty matches.

MADAME ANDRÉ.—The name of this lady, the wife of our distinguished colleague and esteemed friend, M. ED. ANDRÉ, editor of the *Revue Horticole*, was, it appears, inserted in some of the lists of those who perished in the recent frightful catastrophe in Paris. We are thankful to learn that Madame ANDRÉ was not present on the occasion, although she had intimated taking part in the Bazaar some days later, a circumstance which may have given rise to the rumour.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—We are requested to state that the 53rd anniversary festival dinner in aid of the funds of this Institution will take place on Wednesday, May 26, at 6.30 for 7 P.M. (the first day of the Temple Flower Show), at the Hôtel Métropole, under the presidency of the Right Hon. Lord ROTHSCHILD. As a large gathering is expected on this occasion, the Secretary, GEORGE J. INGRAM, 50, Parliament Street, London, S.W., will be greatly obliged if those friends who desire to be present will intimate their intention to him as early as possible, in order that the necessary arrangements may be made.

THE FLORISTS' TULIPS.—Although Tulips are employed largely in conjunction with other plants for creating a floral effect in our spring bedding, there is very little interest taken in the southern counties in the florists' varieties, and in their cultivation for show purposes. The attempt made to revive this interest by holding an exhibition and a Conference in the gardens of the Royal Botanic Society on Wednesday last was only partially successful, there being but one exhibit from an amateur further south than Cambridge. A report of the show is given in another column, and we shall publish next week a short summary of the papers read at the Conference. The Tulip has a life history full of interest, of which the average gardener might do worse than acquire a more intimate knowledge.

SUB-IRRIGATION FOR LARGE FOLIAGE BEDS.—To obviate the difficulties of watering a bed of large foliage plants, the experiment was made the past season of watering a large foliage bed from beneath in the following manner:—A circular bed, 22 feet in diameter, was prepared for sub-irrigation by removing the top soil to a depth of 16 inches, at which depth the subsoil was compact red clay. Three-inch half-round tiles in sections 1 foot long were laid over the bottom of the excavated circle. A line of the tile was first laid across the centre of the bed, the sections being placed 3 inches apart. At right angles to this, were laid branch lines, opposite the spaces

between the sections of the first line, the sections of the branch lines being placed close together. The outer end of the branch lines, and one end of the main line, were then closed with bricks, and at the other end of the main line a section of 5 inch tile, 2½ feet long, was set vertically, as an inlet to the system. The spaces between the sections in the main line were covered with pieces of tile, after which the joints were closed with cement. The tiles were then covered with well-enriched soil to a depth of 24 inches at the centre of the bed, and the surface was gently rounded to the border. The bed was planted June 1 with Ricinus at the centre, surrounded with a group of fifty robusta and fifty Crozy Cannas. Around this was a belt of eighty plants of Caladium esculentum, and these were enclosed with a belt of Verschaffelti and Golden Badder Coeuses, and lastly the whole was encircled with a narrow band of silver leaf Geraniums. Rains came sufficiently often, so that no artificial watering was needed until June 24. On that day, and also on July 7 and 15, and August 6 and 21, water was supplied to the tiles from the Station irrigation system, until the soil of the bed appeared moist to the surface. The quantity of water required to thoroughly wet the soil was very large, amounting to in the neighbourhood of fifty barrels for each watering. How much of this water escaped through the subsoil we have no means of knowing. P. Cranfield, in "Gardening."

KINGSTON ON THAMES CHRYSANTHEMUM SOCIETY.—Judging by the schedule of prizes of the ensuing or twenty-first annual exhibition of this Society, to be held on November 9 and 10 next, the committee have wisely resolved to anticipate the year's falling off in subscriptions so generally expected, and have materially varied the prize-list in an economical sense. It has doubtless been disquieting to find that the balance held over from 1895 of £35 17s. 11d. should last year have become 48s. and now this year's balancesheet shows a present sum in hand of only £3 15s. No doubt the Kingston Society suffers materially because of the enormous growth and immense exhibitions of the National Society: and as if to accentuate this rivalry, we see this year the two shows again are to be held on the same days. The present schedule shows a useful reform in combining the Chrysanthemum plant groups with those of the miscellaneous order, and whilst giving undoubtedly better results, securing a saving of £9. Even the formal-trained plant classes are much cut down, effecting a saving of £10. This reduction will be no loss to the exhibition, seeing that in these days the public are chiefly anxious for cut flowers. Several fourth prizes in the cut-flower classes have been cancelled; but whilst the chief incurred classes remain as before, the twenty-four Japanese class has been converted into one for thirty-six blooms, with a moderate increase in the prizes. The twenty-four Japanese in the Challenge-vase class no doubt suffices for that number of these flowers. This vase is eagerly competed for, and still retains its exceeding interest.

THE WEATHER IN THE NORTH OF SCOTLAND AND ABERDEENSHIRE.—With the advent of the month the weather in the north of Scotland has been of the most wretched description, fierce gales of wind, rain, hail, and snow having prevailed. On Friday, May 7, in some districts in the north-east of Aberdeenshire, the ground was covered with snow to a depth of 2 inches. Vegetation is generally from three to four weeks late; and should these cold, sticky days and nights continue, premature falling of the blossom is sure to supervene, while vegetation generally will receive a marked check.

STOCK TAKING: April.—The Board of Trade returns for the past month show a falling off in imports as compared with the exceptional returns for April, 1896. There has been a heavy falling off in raw materials for textile manufactures, especially in cotton shipments from the United States, and of wool. Food supplies of all kinds have much increased. Bacon, butter, cheese, eggs, sugar, are well to the fore, and dutiable articles make a very fine

show generally. Of course, the war in the East, localised though it be, is answerable for various instances of deficiencies, as for instance, Barley from Turkey; but other countries show so great a desire to do business on our markets, that "minus" returns are not worth recording in the feeding department. The following figures are from the "Summary Tables":—

	1896.	1897.	Difference.
IMPORTS.			
Total value ...	£ 35,808,800	£ 35,136,555	-£ 672,245
(A.) Articles of food and drink—duty free ...	10,377,028	11,752,101	+1,375,073
(B.) Articles of food and drink—dutiable ...	1,886,232	2,116,859	+230,627
Raw materials for textile manufactures ...	7,911,840	5,304,501	-2,607,339
Raw materials for sundry industries and manufactures ...	3,224,676	3,207,117	-16,559
(C.) Miscellaneous articles ...	1,291,680	1,088,629	-203,051
(D.) Parcel Post ...	74,390	73,141	-1,249

It may here be noted that the imports for the first four months of the year are placed at £152,964,781, as compared with £148,126,142—a gain of £4,838,639. By the way, the total value for the month of April was £95,126,555 against £95,808,800—a falling off of £672,245. The figures relating to fruits, roots, and vegetables are as under:—

	1896.	1897.	Difference.
IMPORTS.			
FRUITS, RAW.			
Apples ... bush	93,234	336,374	+243,140
Cherries	15	521	+506
Plums	15	—	-15
Pears	268	1,580	+1,312
Grapes	2,363	2,042	-321
Unenumerated ...	54,269	56,019	+1,750
Onions	375,650	377,217	+1,567
Potatoes	63,439	80,167	+16,728
Vegetables, raw, unenumerated ... value	£103,359	£135,240	+£31,881

Some of these figures are rather astounding; the value of the Apple import was increased by £57,670. Other totals are also very suggestive in their way. Proceeding to—

EXPORTS.

The month's business foots up at £19,700,122, and this, compared with the returns for the same period last year (£18,450,227) shows a gain of £1,249,895—distributed over all the sections in a very satisfactory manner. Woolless and linens have gone up for the United States in the exports, and though in India famine and disease still lay their paralyzing hand on trade, other places manage to make up a good "covering," and leave a margin to the profit side of the account. Tinkering is still going on with the tariff of the United States; but their next door neighbour—Canada is about to shift her business to the United Kingdom, doubtless a good termination on the part of the Dominion, which appears to have a great future in store. The trade with us in cereals and food supplies generally increases day by day, and it is known there is still some unappropriated capital in "the Old Country." It is worthy of mention that the exports for the first four months of the year have reached £78,998,309, as against £79,750,436—a decrease of 752,127. The reduction is not a very great one; it may as well be turned into an increase by next report.

"THE COUNTRY GENTLEMEN'S CATALOGUE."

—This book, published by the Catalogue Publishing Company, Ltd., 49, Bedford Street, Strand, contains a great variety of useful and interesting information sandwiched in between an equal number of advertisements. By reason of its indexes the work is rendered useful for reference now, whilst it will prove a veritable mine to the historian of the future in compiling his review of the country life and its requirements in the last years of the nineteenth century.

"DICTIONNAIRE PRACTIQUE D'HORTICULTURE ET DE JARDINAGE."—The 60th part of the French edition of what is called in common usage, *Nicholson's Dictionary*, is now published. It is mainly taken up with Roses and subjects relating to them, an indication of the thoroughness with which the book is produced. The publisher is OCTAVE DOIS, 8, Place de l'Odéon, Paris.

PUBLICATIONS RECEIVED.—New York Agricultural Experiment Station, Bulletin No. 116, January, 1897, *Report of Analyses of Commercial Fertilisers for the Fall of 1893* (Geneva, N.Y.).—From the Government Agricultural Experiment Station for North Dakota, *New Studies upon the Smut of Wheat, Oats, and Barley*, with a résumé of Treatment Experiments for the last Three Years, by H. L. BOLLEY.—U.S. Department of Agriculture, Division of Entomology, *A Study in Insect Parasitism*, by L. O. HOWARD, mentions many of the principal insect parasites, and their influence in reducing garden and crop pests.—*Agricultural Gazette of New South Wales*, February, 1897. The list of useful Australian Plants is continued, also there are notes on the Weeds of New South Wales, Physiological Role of Water in Plants, Entomology, and other similar subjects.—*Proceedings of the Agri-Horticultural Society of Madras*, October to December, 1896.—*Agricultural Journal, Cape of Good Hope*, March 18, is devoted to the interests of Fruit and Nut Culture, Stock-farming, Dairying, Forestry, Beet-Sugar Manufacture in America, and similar topics.—University Extension College, Reading, *Third Annual Report*, dealing with the field experiments on hay, pasture, Potatoes, Swedes, and Mangels carried out last year.—*Bulletin de l'Association pour la Protection des Plantes*, No. 15 (Geneva).—*Annali Agronomici*, April 25, contains several interesting papers.—*Bulletino della Società Botanica Italiana*, Nos. 2 (for February and March), and 3 (for April).—*Nuovo Giornale Botanico Italiano*, April, contains articles entitled, *Prodromus Bryologia Boliviana* by K. MULLER; *Coniferae de China*, by L. DEISSNER, and others.—*English Mechanic and World of Science*, April 16 and 30.—*Parasitic Flowers of Garden and Greenhouse*, Nos. 35, 36, and 37.

NOTICES OF BOOKS.

THE FORCING-BOOK: A Manual of the Cultivation of Vegetables in Glasshouses. By L. H. Bailey.

The British horticulturist who consults Professor Bailey's recent work, *The Forcing-book* (of the Gardener Series) will find therein a great deal of new and sound practical information on the cultivation of vegetables under glass. Although the author treats of and records the results of experiments tried in several important agri-horticultural stations in America, the work, nevertheless, is one that we can confidently recommend to the notice of readers of the *Gardeners' Chronicle* who, by making due allowance for the difference in climatal conditions prevailing in the Correll and other experimental stations in America and Great Britain, may easily apply, and practise in a modified form, many of the methods of procedure indicated in *The Forcing-book* with advantage in British gardens, in which there is a growing demand for supplies of good forced vegetables.

The Forcing-book consists of 279 pages, including five pages of index at the end, and thirteen pages of contents, and a brief but lucid preface. It is profusely illustrated, but by some oversight or other no index is given to the illustrations (eighty-eight in number), an omission which is to be regretted. Chapters are devoted to the construction of various kinds of forcing-houses and frames, bells and benches for growing the several kinds of vegetables on, heating, and cost of forcing-houses; management of the forcing-house, temperatures for the various crops treated of, and which are reliable and carefully arranged; soils for forced vegetables, the question of fertilisers, watering, ventilating and

shading, pollination, insects, and diseases. The remaining ten chapters are devoted to the forcing and general management of Lettuce, Cauliflower, Radish, Asparagus, and Rhubarb; miscellaneous cool plants, including the Pea, Celery, salads, pot-herbs, and Mints, Watercress, Parsley, Spinach, Dandelion, Mustard, Onion, Beets, Carrots, Parsnips and Potatoes. Tomatoes, Cucumbers, and Melons are accorded a good deal of space, as the importance of the crops entitles them to.

The cultural instructions on the Melon (reproduced from a paper read at one of the meetings of the Royal Horticultural Society in 1896), are identical with instructions given in the *Gardeners' Chronicle* from time to time during the past fifteen or twenty years, under the headings of "Melon Culture" and "Fruits under Glass." Good illustrations of Bleuheim Orange, Hero of Lockinge, and Masterpiece Melons are given in pages 216, 217, and 218.

The Tomato (p. 153), the author says, next to the Lettuce, "is probably the most important vegetable grown in American forcing-houses. Its only close competitor for this honour is the Cucumber. Winter Tomatoes always find a ready sale at prices ranging from 25 to 75 cents per pound. Even after the Florida Tomatoes come upon the market in late winter, a good quality of house-grown fruits continues to sell well in every good market. The crop is one which demands a high temperature, an abundance of sunlight, and great care in the growing, but the profits, under good management, are correspondingly high."

Professor Bailey in referring to the importance of sunlight in connection with successful Tomato culture says, "The importance of direct and strong sunlight was well illustrated in one of our experiments. At one end of the house is a low building which shaded a part of the plants after 2 or 3 o'clock. The plants within 3 or 4 feet of this building, which were thus deprived of direct sunlight for half the afternoon, bore [as might be expected under the circumstances] no fruits whatever, although they were strong and vigorous. At 6 and 7 feet away some fruits were borne, but it was not until about 15 or 20 feet from the building that a full crop was obtained." We may say, that if Grape-vines, Peach, and other fruit trees were grown under similar adverse conditions as regards light and shade, the results in the course of a few years would be little better. With reference to "Soil and Fertilisers" (p. 154), the author writes, "Nearly all writers upon house-cultivation of Tomatoes assert that the soil should be only moderately rich, because heavily manured plants are over-vigorous in growth, are generally unproductive, and are particularly liable to disease; and the additional cost of training is said to be considerable." "Our experience," writes Professor Bailey, "empirically contradicts this supposition. Heavily manured plants undoubtedly require more care in the pruning, and it is possible that when not properly handled they may be more liable to mildew, because of the dense and crowded growth; but, on the other hand, we always get the best yield from the strongest plants, and we find the extra cost of training to be of little account. We grow the plants in rich garden loam, to which is added a fourth or fifth of its bulk of well-rotted manure, and when the plants begin to bear, liquid manure is applied nearly every week, or a top-dressing of manure is given." In the matter of soil, our own experience teaches us that better results are obtained from plants potted or planted in rich garden loam, without the addition of well-rotted manure, or manure of any kind, as this would tend to the plants making a too luxuriant and sappy growth, resulting in a late show and setting of the flowers, and consequent lateness of crops. When the plants have set one or two clusters of fruits and onwards, is the time to apply frequent manurial dressings either in a liquid state or as a top-dressing, in order to assist the plants in the swelling and ripening of heavy and profitable crops of fruit without any fear of the plants making an unduly vigorous growth in consequence thereof. At p. 156, fig. 50, a good illustration is given of the early fruitfulness of Tomato plants

struck from cuttings and growing in a shallow trench or bed, the plants always evincing a disposition to fruit nearer the ground than seedlings; strong evidence this in favour of raising the plants from cuttings. These, if taken from the lateral growth when from 2 to 3 inches long, and inserted in pots or boxes filled with light soil, and placed in heat and watered, will take root in a week or two.

In the pages (49 to 92) on the management of the forcing-house, are given sound practical instructions upon the culture of the leading kinds of vegetables under glass, as also are the results (in a tabulated form) of experiments with various kinds of artificial manures applied to Tomatoes, Lettuces, &c. *The Forcing-book* deserves a prominent place in every gardener's library.

GLEANINGS ON GARDENS.

This is the title of a book originally published in 1829, and now again privately printed for Arthur L. Humphreys, 157, Piccadilly. It consists in a number of observations, some more, some less pertinent to gardens, but so disconnected and fragmentary as to be of little use to the gardener. To those who want something to fill up their leisure time agreeably, we recommend the perusal of this unpretentious little volume, which will yield them many an interesting excerpt. The work has an index, for which the reader will be specially grateful.

FIG. 111.—DUNN'S TURF-CUTTER.

NEW INVENTION.

A NEW KIND OF TURF CUTTER.

We give a sketch (fig. 111) of a very useful tool invented and patented by Mr. Dunn, blacksmith, Broxburn, near Dunbar, for restoring bare or worn patches on golf greens. Attached to the two ends are adjustable cutting-knives, which at their extreme distance cut with the greatest facility, on the principle of an auger, a circular turf of a maximum diameter of about 12 inches. This turf is transferred to the corresponding place on the green, and the identity of the size of both secures a fit so exact as to make the job much superior to spade work. It also enables the work to be more quickly done. On the Dunbar course, its success is described by members of the club to have been very marked. The greens have been repaired by its agency, and they are now in finer condition than ever before. The tool is a simple one, but the simplicity is its great merit.

HOME CORRESPONDENCE.

EE-LWORMS IN PASTURE.—In answer to the enquiry concerning this matter, it may be said that if the eel-worm is in the pastures, the fested turf should certainly not be used for potting purposes, or the pest may spread throughout the whole establishment. As a remedy to the pastures themselves, apply a dressing of 6 cwt. of kainit and 3 cwt. of basic slag per acre, mixed together; 1 cwt. of bone meal added in would prove an advantage. This manurial dressing would improve the pasture, and cause it to recover from the attacks of the eel-worm, but I do not say it would entirely destroy the pest. For potting purposes, take some of the turf, and after breaking up finely, mix it in a manurial mixture as quoted above; keep separate from other soils, and watch the result upon the growing plants. A little sulphate of iron dissolved in the water for watering operations would assist the plants in overcoming the eel-worm. *J. J. Willis, Harpnoton.*

METHODS OF PROPAGATION.—The articles by "Experience" in the *Gardeners' Chronicle* have greatly interested me, and illness has alone prevented me from earlier writing the few notes which I now venture to offer; as, valuable as are the various directions given, I much regret that "Experience" has not amplified some of his remarks, such, for instance, as the following: P. 271: "The Manetti stock is good for all classes of roses." May I be pardoned for inquiring if "Experience" has ever seen a quarter of Mârchâle Niel or Gloire de Dijon on the Manetti two or three years old? I am aware you may find beautiful plants the first year, but how about the following ones? P. 293: "Rhododendrons. There are grave reasons for the latter being increased by layers." May I ask why? I am under the impression that by grafting Rhododendrons on good stocks, one might buy the horse, while by growing in layers one could scarcely purchase the saddle! P. 293: "Rhododendron stocks should be grown one year in pots." I should like to hear the ordinary nurseryman's opinion of that expensive process, and whether the game would really be worth the candle. Perhaps some of your readers will kindly favour me with their ideas on this point. P. 432: "For the many fine varieties of Larch, as Kumpferi (golden Larch), use the common Larch." Will "Experience" have the great kindness to tell me where a specimen of Kumpferi grafted on the common Larch can be seen? I should certainly make a pilgrimage to it at once. P. 673: "Cotoneaster.—The most useful and showy is Hookeri, alias Simonis, either grafted low, or about 2 feet high." Does "Experience" think it really worth while grafting this Cotoneaster when there is absolutely no difficulty in growing it 3 or 4 feet high in one season? I trust "Experience" will pardon my questions; but when one is blessed (or cursed) with an enquiring mind, it is difficult, on reading such suggestive articles as those on "Methods of Propagation," not to strive to go a little further, and learn a little more. *Charles Noble.*

— Allow me to reply if I can in the same spirit as Mr. Noble, prefacing my answer with the remark, that as my experiences are recollections of the past, it is possible, may I be allowed, I may have made a few errors. Again, the articles were not written with the intention of teaching nurserymen of any standing, but young gardeners and amateurs. As regards Mârchâle Niel Rose on Manetti, and Gloire de Dijon on the same stock: without reference to the article, I do not think I advised the use of the Italian stock, but recommended De la Griffierie and "Napoleon." To answer the question as though I were before a bewigged judge, I have seen a quarter of two to three-year-old Niels and Dijons, based on the Manetti, but I cannot say they looked happy! Rhododendron: If Mr. Noble will refer, he will find in that article I am only alluding to inside grafting. Later on, the grafting of Rhododendrons and other subjects in the open was dealt with. The "grave reason" for preferring layer plants is, that with such there is no danger of suckering. Who has not seen beds of Rhododendrons in which the stock (usually R. ponticum) has quite overgrown and killed the more delicate hybrid varieties, the average gardener and amateur not seeing the mischief until too late! The process I have indicated is the one usually adopted abroad, and yet the "foreigner" somehow manages to undersell the English nurseryman; and it can be done in the dead of winter, when the nurseryman is often glad to find an inside job for his

staff. Unfortunately, the pinctum in which, unless my memory tricks me, could be seen two small specimens of *Larix* (Pseudo-*Larix*) Kempferi, is no more. These were not my own working, but came, I believe, from Messrs. Cripps & Son. One threw up suckers from the base, and this appeared to be a glaucous and vigorous form of *Larix*, not improbably *L. leptolepis*. Before I could determine with any degree of certainty, my knife-man took off this growth, and it was burned with the rubbish. I do not grow much under my error, as I find scientists and professors are still undecided where to locate *L. Kempferi*. It is, I think, amply worth a stick to credit Colonel Simonsen on Thors, as the stick imparts to the scion a short-jointed and compact habit, at the same time rendering it more fruitful. It is proposed to publish "Methods of Propagation" in book form, and I hope Mr. Noble will allow his notes to be printed with mine. I thank him for his friendly criticism. *Experience*. [These articles have been much appreciated, but will be none the worse for criticism. Ed.]

DAPHNE PONTICA is deserving extended cultivation. The delicious fragrance of its flowers, which are usually produced early in April, and continue in bloom for about a month, is not sufficiently known. In early morning and evening, bushes white in flower scent the air around for some considerable distance. For cutting purposes generally, the branches, with greenish-yellow flowers and foliage, of this *Daphne* are admirably adapted. The flowers keep sweet and fresh in water for about a week in an ordinary living room. A native of Asia Minor, and introduced as long since as 1757, it is quite hardy, at least in the south of England, and grows freely in any moderately light loam or peaty soil. It may be increased readily by layers, and grows to about 4 feet or more in height. *C. Herrin*.

GARDENERS AND THE DIAMOND JUBILEE.—The government has proclaimed that June 22 next shall be a general holiday throughout the kingdom. I have noticed that gardeners rarely enjoy, in relation to holidays, the privileges accorded to workers in other vocations. That may be better for them, or it may not. Everything depends on how the privileges are utilized. But the less gardeners do feel that in regard to this matter they are not always treated quite fairly. If to keep June 22 as a general holiday is to exhibit true patriotism, then keeping gardeners at work all day will be unpatriotic. In any case, there can be no good reason for cutting off these workers from the privileges given to other workers in other vocations. This remark applies with equal force to the employes in nurseries and market-growing establishments. No doubt, in many directions the preparations for observing Jubilee Day will entail on these concerned unusual labour prior to its date; that is natural. But that supplies an additional reason why a holiday should be given to nursery or garden staffs on June 22. I have seen with much regret that two large semi-metropolitan shows are to be held on June 23. A very large number of nursery and garden employes will have perforce to be kept hard at work all Jubilee Day preparing plants, flowers, &c., and loading for these shows. Heads of firms and other employers, or head gardeners, might well in this matter show that they can be unselfish and patriotic by ignoring these shows, or they can give evidence they are not so by keeping their people at work all day preparing for the shows. *D.*

SOLANORA GRANDIFLORA Many of those interested in gardening have not probably had the opportunity of seeing this noble plant in flower, and were therefore surprised at the splendid illustration given recently in the *Gardeners' Chronicle*. There is a plant of exceptional size in the large Succulent-house at Kew. This handsome example is planted out in the large central portion of the house almost beneath the ridge. From the ground to the ridge of the house—a distance of 10 feet or 12 feet, probably—a woody trunk like stem, the size of an average man's arm, has grown; and reaching the roof a head has formed, with branches extending both ways fully 40 feet. Close to the glass, with ample ventilation from large sliding lights, that at will may be run up or down, a thorough ripening of the extended growth is effected. During November last the plant flowered splendidly, and as I saw it on the 23rd of that month, it was a most handsome flowering-plant. To me, with much prominence of such little-grown plants can scarcely be given, especially when, as is abundantly clear at Kew, they may be

grown to such proportions, and with such success, in a house comparatively cool and dry, as is the Succulent house in the Kew Gardens. *J.*

APPLE, BRAMLEY'S SEEDLING.—I have been much interested in the correspondence respecting this Apple, as I have lately planted both standard and dwarf trees. The standards are upon the Crab stock, and I planted them last autumn. The dwarfs are on the broad-leaved Paradise. I obtained them direct from Mr. Merryweather, and they were planted this spring. The trees are in the same plot of ground, the dwarfs about 20 feet from the standards, in shallow light loam over gravel, the whole of the very old thick turf having been dug in last summer. My object is to test both varieties on the Crab and the broad-leaved Paradise stock. If it would be of any use to the readers of the *Gardeners' Chronicle*, I should be pleased to report upon them later. *W. S. Bailey, Parkside Road, Hounslow*. [Kindly do so. Ed.]

BIRDS AND CHIMONANTHUS.—Have instances come under your notice of birds eating the young wood-buds of *Chimonanthus*? They have picked three parts of them out of our large plant of *C. fragrans grandiflorus* this year. I think tom-tits were answerable for the damage, but unfortunately did not notice it until the mischief was done. *Edw. Burrell*.

MODERN TREATMENT OF BULBS.—After reading the remarks on this subject at p. 308, it struck me that "Modern Methodism of Herbaceous Plants" would have made a more fitting heading to Mr. Wm. Earley's note. To Mr. Jordan's method of storing in boxes and the like, I have nothing to say; but of the wisdom of lifting bulbs of *Narcissus* "early," and denuding them of every vestige of foliage to within "an inch of the top of the bulb," a good deal might be said that would place a very different glow of colour on Mr. Earley's remarks in your last issue. Does Mr. Earley intend in all sincerity to tell the readers of the *Gardeners' Chronicle* that the best beds of bulbs in the Regent's Park are obtained by such a method of defoliation as this? If so, I fear the proverbial grain of salt will be very necessary wonder, too, what Mr. W. Barr would think of such a suggestion of mutilation amid the acres of *Dafodils* at Ditton. Obviously, in a public park such as the one named, there is a need for as early lifting as possible of all bulbs that occupy the beds, which, in the case of *Narcissus*, need not be, if these were planted deeply. It is, however, a totally different thing to advance what necessity compels as part of a perfected modern idea, or to infer that such treatment is either judicious or sound; much less that it is likely to bring the best results in any future year. *E. Jenkins, Hampton Hill*.

SWEET VIOLETS.—It has always been a special pleasure to discuss any matter horticultural with my old and enthusiastic friend and florist of world-wide fame, Mr. Henry Cannell, and of Swanley, and I need hardly assure him in particular, and your readers in general, that in omitting Swanley White from my list, I had no intention of ignoring its merits—quite the contrary. For many years I have been assuring all whom it may concern that the two *Violets*, *Comte Brazza* and *Swanley White*, were one and the same, and for all practical purposes identical. Hence, all that I have said about *Comte Brazza* being almost the only white *Violet* worth growing, is equally true of *Swanley Double White*. Being the same in constitution, size, form, purity, of paper whiteness, of course the *Violets* are alike good under either name. I took some pains to settle the point years ago, and plants from the most diverse districts came quite true to character under either name. Not that selection of runners and methods of cultivation have no effect on the hardiness of the plants, their time of blooming, size, number, duration of the blooms they have; but this particular *Violet*, under either of its names, may be grown to flower as freely. I am, obliged for Mr. Cannell's latest contribution to the subject, and I am sure he will allow me to say that I was referring to single white *Violets*, and not doubles, when I wrote of some so-called white *Neapolitan* as of doubtful authority. And then there are *Ransom's White*, tinged with pink, and *White Czar* being back at times to purple, and re-blooming probably to its white hue. And then among other doubles, *Belle de Chateaux* is not always pure white, and is of little use for quantity. *The White Queen* is fitted with rose, *Queen of Violets* tinted with violet-rose; and *Parmaensis* flore-pleno, white, striped with rose.

Beautiful as several of these double *Violets* are they are spoilt for many decorative and market purposes by their tints or stripes of colour. Hence, we fall back on *Swanley White*, as taking rank with *Marie Louise*, *De Parme*, *Neapolitan*, &c. Readers will please to note that the two or more *Violets* that I bracketed as identical are in addition to the one double with two names—*Swanley White* and *Comte Brazza*—*De Parme*, *Lady Hume Campbell*, *Marie Louise*, *New York*, and *Venice*. May I also hope that *Violet* growers will not have their quiet and popular flowers grown out of character and size into *Violets* without a vigorous protest against a species of evolution that may not prove fruitful in pleasure or profit. *D. T. Fish*.

FAUIT PROSPECTS IN NORTH DEVON.—These are the worst that have been experienced for fifteen years. Peaches are blistered very badly—indeed, there is not one good set, even where double nets have been used over the trees. Pears and Plums bloomed well, but there is scarcely any fruit. Currants suffered badly from frost. The Apple-blossom suffered very much from the cold easterly winds, hail, and heavy rain, and it was injured very much in many cases whilst in the bud. It would be interesting to know if this failure extends very far. *G. S.*

BRANCHING TULIPS.—In the report of the meeting of the Scientific Committee of the Royal Horticultural Society, in *Gardeners' Chronicle*, p. 310, reference is made to *Proserpine Tulip* with an axillary flower. Will you allow me to point out that this is of very frequent occurrence with this variety, and a double variety named *Titan*. I send herewith a specimen of the former taken from a clump of six roots, of which three have produced an axillary flower. In the Penge Recreation Ground are two beds of the same variety, and in both several examples are to be seen. *S. B. Dicks*. [By no means uncommon, but we were not aware that the conditions occurred specially in particular varieties. Ed.]

CULTURAL MEMORANDA.

DOUBLE CHINESE PRIMULAS.

In April, cuttings are taken from plants that have been growing in a temperature of 50° to 60° during the winter, and are consequently in a suitable condition. The tops are cut off level with the soil, and the strongest selected and trimmed as cuttings, when they are inserted singly in 2½ inch pots, in a mixture of leaf soil, a little peat, with a free addition of coarse sand, the foliage tied up, and the plants well watered and plunged in the propagating case, where a steady bottom-heat is maintained, and a little air is constantly admitted at the back to keep the foliage comparatively dry, as the leaves, being hirsute, soon commence to decay if constantly wet. They are given excellent care in watering, and when the pots are fairly full of roots, the plants are gradually prepared to withstand a lower temperature, till eventually they are transferred to a cold frame. The plants are then ready for a final shift from 2½-inch pots to 6-inch pots. Although I do not favour over-potting any kind of plant, in this case I make an exception, as I am convinced that the less frequently this subject is transferred from one pot to another the better. Of course, unusual care has to be taken in watering and the general management of the plants at this stage, but the results fully compensate for the extra labour and time. At the final potting, good leaf-soil is the material chiefly employed, with a small portion of loam, and a plentiful addition of coarse sand and charcoal; good drainage is essential. After the plants have been potted, the frame is kept close for a few days, when air is gradually admitted until the plants can bear full exposure, with shade from bright sun. During quiet rainless nights, the lights of the frame are removed altogether, the dew being very beneficial to the plants. When the nights become too cold for them to remain longer in the frame, they are transferred to a span-roofed pit, where the air is kept free and buoyant with the aid of artificial heat. During growth, any flower-buds that appear on the plants are promptly pinched off; but at this stage they will throw up their flowers *en masse*, the usefulness of which is beyond dispute. *W. H. Sharpe, Highwood Gardens, Rochampton*.

SCOTLAND.

NOTES FROM EDINBURGH ROYAL BOTANIC GARDEN.

Rhododendron Nuttallii.—Two plants of this magnificent Himalayan species are now carrying twelve trusses of their immense flowers, some of which are more than finches across the corolla. They are white, with a tinge of pink, especially upon the outer surface, while the base of the inside of the tube is yellow. For large winter gardens it is an excellent plant, and its rather straggling habit of growth may be tempered by occasionally pruning the longer growths.

Tricuspisidaria dependens under cultivation seldom grows more than a few feet in height. The stems are covered with brownish hairs; the leaves are a rated and alternate, dark green above and lighter beneath. The flowers are axillary and solitary, suspended upon peduncles about 2 inches long, the corolla being a deep blue-red colour. Several months intervene from their first appearance till they expand, but they last a good time after opening. It does not seem to become easily established under cultivation; a cool greenhouse and a rather shaded position, with a peaty soil, gives fairly good results. If allowed to become dry, it is apt to be attacked by red-spider.

Erica Chantisonii, when well grown, is quite a charming plant for greenhouse decoration. It is compact in habit, seldom becoming more than a foot or eighteen inches in height, with very stem, clothed with immense numbers of light green leaves, about a quarter of an inch long. The small flowers are produced in great numbers, and the rose coloured, almost campanulate corolla, is made more effective by the chocolate coloured anthers. Plants propagated from cuttings two years ago are now in full flower, and are about 6 inches high. It requires no more than the ordinary culture afforded Cape Heaths. A good figure may be seen in the *Bot. Mag.* t 6108, where it is stated to grow at a considerable elevation near Grahanstown.

Terrestrial Orchids.—Among the most conspicuous in flower at the present time is *Ophrys speculum*, a native of Southern Europe. It is about 6 inches high, has flowers with greenish sepals and petals, but the lip is a combination of bright colours, of which the steel-blue of the disk is most prominent, edged with a gold band, the margin being maroon purple. Another species is well figured in the *Gardener's Chronicle* of 1872, p. 605, viz., *O. tenthrinifera*, from the garden of H.R.H. the Comte de Paris, where they were successfully cultivated. Several species of *Orchis* are also in flower, viz., *O. sambucina*, which bears an oblong spike of yellow flowers; *O. provincialis*, *O. morio violacea*, and one or two others. They are grown here in a cold frame, and plunged during their resting period in Cocoa-nut fibre. *R. L. H.*

LAW NOTES.

ROBINSON v. WARD, LOCK & Co. (LTD.)

The plaintiff in the above-named action, on the 2nd ult., obtained from Mr. Justice Kekewich, in the Chief Division of the High Court of Justice, an order perpetually restraining the defendants from printing, publishing, selling, or disposing of, and from advertising, offering, or exposing for sale any newspaper, periodical, or publication by the name of *Gardening Illustrated*, or by any other name so similar to *Gardening Illustrated* as to induce the public to believe that such newspaper, periodical, or publication is the paper published by the plaintiff.

SOCIETIES.

THE HAMBURG HORTICULTURAL EXHIBITION.

MAY 1 to 9.—Among the exhibits at the spring show, of which we last week gave some notice, were also the following flowering shrubs, Lilac, Laburnum, Prunus triloba, and others, from Mr. F. PAULSEN, and a group of *Ficus*, *Tree Ferns*, *Inc. atrophillanum*, and *Cocos Weddelliana* from M. E. SZREKET, of Wandsbek.

M. KOSTER, Flis, of Boskoop, sent *Azalea mollis* - *siamensis*; M. BERNARD SPAAL, Liboedonsch Dorsiana; M. GOFFEL, a fine group of Palms and Pandanus; and Madame W. D. HELL, Lilies of the Valley, growing under *Dioon spinulosum*. M. CH. VUUSTEER exhibited some fine Palms; M. DESMET FRÈRES, a New Zealand plant (now 1896); Kasia, *Rubus chrysanthemifolius*; M. SCHUYTER, Camellias; M. H. BERNER, English Pelargoniums; Madame HELL, *Ptycho-sperma Alexandria*, a fine specimen; M. ERNST BERNAR, hybrid *Citricaria*; and M. PETERSEN, some fine white and rose *Hortensia*. M. ERNST BERNER also showed *Citricaria hybrid grandiflora*, and some *Coleus*, Japanese Maples, and Tulips.

In a gallery which might be called the Birch-room, being supported by trunks of this tree, and having its walls also covered with the bark, MM. GOZKE & HANKERS, of Wandsbek-Marienholz, displayed Tree-Peonies, including the varieties *Reine Margherite*, of pale, very bright red; *Comtesse de Tuler*, white, and a flesh-coloured; *atrosanguinea*, and *Louise Mouchelet*.

M. FR. AD. HAAGE, JUN., had arranged in a Japanese style *Hedera madericensis*, *Cereus*, and *Cacti*; M. ENGELBRECHT, of Hamburg, sent some fine *Caladiums*; M. L. DUVAL & FILS, Antwerp; and M. C. L. KRISTENSE some more *Caladiums*, notably *Rouletii*, *Aloides*, and *Guarantia*; M. DE SMET FRÈRES, hybrid *Anthurium*; M. M. DUVAL ET FILS, flowering Bromeliads, *Vriesea corallina*, *V. Plumieri*, and *V. rex major*; and M. L. DE SMET-DUVINIER, *Caladium de Schroeder* and *Anturium Divisvarianum*.

One pretty group included (from M. STOLTE, of Wandsbek) a fine collection of Orchids, including *Millettia*, *Rosea*, *Lycaste Skinneri*, and a variety with white sepals, petals very dark red, and a white lip; *Cattleya Trianae*, *Schroederi*, *S. albescens*, *Mendeli*, *intermedia grandiflora*, *Oncidium leucobichum*, and *Bifrenaria Harrisoni*. Madame W. D. HELL showed *Lelia purpurata*, *Marsiplococcia discolor*, *Cypripedium corobis*, and other general orchids.

FRANZ DÖSSNER, among other plants, sent a fine *Pitcairnia grandis*, *Medinilla magnifica* with twenty racemes, *Caladiums*, *Orchids*, *Anthuriums*, *Helleborus*, *Alocasia*, *Berberis*, *Berbericella*, and *Sobralia macrantha*.

M. ALBERT WAGNER showed some fine Palms, among them *Chamaedorea* with more than a hundred leaves; *M. Goss* & *KONSTANTIN* arranged an interesting group of *Primula Sieboldii*, including some excellent varieties; M. J. SCHMIDT, *Todea superba*; Mr. OSCAR TIEFENHAU, a mixed group; M. G. FROBER, flowering shrubs; and M. A. J. PETERSEN, of Hamburg, pink *Hortensia*, dwarf, and well-coloured. M. THUMANN also sent a fine group of *Agave*, *Adonis*, *Dasylirion*, *Yucca*, and other plants.

ISLE OF WIGHT HORTICULTURAL IMPROVEMENT ASSOCIATION.

MAY 8.—The monthly meeting of this Association was held at Ryde Town Hall on the above date, when an excellent paper was read by Dr. GROVES, Chairman of the Association, on "The Influence of Microbic Life in the Nutrition of Plants."

Previous to the meeting a large number of the members visited the Rev. H. EWBANK'S garden at his invitation, and saw a very much interested in the variety of things they saw. The following are a few of the many good things to be seen in bloom there:—*Pononia Enodi* and *P. tritermata*, *Camassia Leichtlinii*; *Artemisa chalcidoides*, *Magnolia stellata* and *Lemni*, Himalayan *Rhododendron*, *Choisya ternata*, *Dodecatheon integrifolium*, *Rubus delicious* and *articus*, *Trillium grandiflorum*, and others. *Nella speciosa*, found Hildreichii, *Euphorbia pilosa* maritima, *Cypripedium calceolus*, *Tulipa Greigi*, *T. turcica*, and others; *Morisa hypogea*, and of the *Oncopeltis* lilies, *Iberica*, *lupina*, and *Susiana* were beautiful, whilst several others were nearly out, as were also the *Korolkowii*, and three or four varieties besides the type.

By permission of Mr. George HULL, of Appley Tote, many members visited the gardens at that place. The fine Oaks, Japanese Maples, *Azalea mollis*, and the fine specimens of *Choisya ternata* in full bloom were objects of much interest, as were also the magnificent Palms and Camellias.

ROYAL HORTICULTURAL.

MAY 11.—The last of the ordinary meetings of the committee previous to the gathering in the Temple Gardens on the 9th inst., was held on Tuesday last in the Drill Hall, James Street, Westminster. On such occasions there is usually a comparatively weak display, owing to the efforts of exhibitors to do their very best at the Temple. Contrary to past experience, however, there was an excellent display on Tuesday of plants and flowers in season, but little fruit. Conspicuous were the collections of Rose plants and blooms from several establishments. Roses have rarely been so shown in the Drill Hall as on this meeting to better advantage. The space reserved by Orchids was not greater than the average of the rest of the exhibits included a large number of Tulips, *Gloxinias*, hardy pinks, sprays of ornamental shrubs, and miscellaneous subjects presented for Certificates. A very instructive Lecture was delivered during the afternoon by Mr. GEORGE MASSEE of Kent, upon "Diseases of Plants," which was illustrated by lantern views.

Floral Committee.

Present, W. Marshall, Esq., in the chair; and Messrs. Jno. FRASER, C. T. DRIERY, H. B. MAY, H. HERBST, R. DEAN, Jas. HUDSON, Jno. JENNINGS, J. F. McLEOD, H. S. LEONARD, Geo. NICKOLSON, J. FRASER, R. M. HOGG, W. BAIN, J. D. FAWCETT, E. L. MAWLEY, J. W. BARR, J. WALKER, H. J. JONES, D. B. CRANE, E. BECKET, and Rev. G. H. Englehart.

MR. THOS. S. WARE, Hale Farm Nurseries, Tottenham, in a collection of hardy plants in flower, including a good representation of species that bloom during May. Most of these were shown in shallow earthenware pans, 15 or 18 inches across, that permitted of a number of small pots being plunged in Cocoa-nut refuse in them, thus obtaining a small group of each variety. Several *Saxifragas* were shown in this manner; also the blue-flowered *Lithospermum prostratum*, varieties of *Iris pumila*, *Asteris odorata*, a pretty white-flowering little plant, with scent of Hawthorn; the golden form of *Spergula pifera*, *Eriopus albus hirsutus*, *Alyssum saxatile compactum*, *Ranunculus pyrenaicus*, *Thellium europaeum*, &c. *Cypripedium montanum* and *calceolus* were shown, and many other pretty and rare species of hardy plants (Silver Flora Medal).

MESSRS. J. CHEAL & SONS, Lowfield Nursery, Crawley, made an exhibit of sprays of flowering and ornamental shrubs, conspicuous amongst which were the double white flowering *Prunus sinensis*, *Viburnum Lantana*, *Berberis vulgaris purpurea*, and *B. buxifolia*; *Galearia scoparia*, *Pyraea Malus floribunda*, *P. ringo*, and others. Messrs. CHEAL also exhibited a few sprays of *Viola* in variety (Purple Bankian Medal).

Floral arrangements of cut flowers were shown by MESSRS. KEMP & WILSON, 85, Mortimer Street, W. Though not novel in design, the wreaths, crosses, sprays, and baskets were of much merit (Bronze Bankian Medal). Some magnificent sprays of *Hymenocallis macrostaphana* in a vase were shown by Mr. HUDSON, and to the Messrs. R. ROTHSCHILD, Gomersbury House, Acton. Being arranged tastefully, the exhibit was a most pleasing one.

GLOXINIAS were shown by Mr. JNO. R. BOX, West Wickham and Trowdon, who had a group of plants in flower, arranged in a most acceptable form. Several *Viola* and *Viola Bogdanii* in several varieties were of much merit (Silver-gilt Bankian Medal).

An Award of Merit was recommended to Lilac Senatorial Holland, shown by Sir TREVOR LAWRENCE, Bart., Burford, Dorset (gr. Mr. Bain). It is a double-flowering variety, produced in uncommonly large sprays.

MESSRS. JAS. VYLLIE & SONS, Virginia Exotic Nursery, Ch. Lea, exhibited several *Stropeocarpaceae*, and were recommended an Award of Merit for *S. achimiflora*. The flowers are a pretty mauve colour, and in shape resemble those of an *Achimenes*; they are produced on rather long scapes, which branch considerably. It is the result of crossing one of the hybrids with the species *S. polyanthus*, and may be termed a capital break. Amongst other plants Messrs. Veitch exhibited *Cytisus biflora*, *Deutzia parviflora*, *D. discolor purpurascens*, with small flowers, the petals of which are distinctly purple on the exterior, *Oleandra indica*, and a batch of plants in flower of an effective *Pelargonium* named *Bryant*; also plants of *Deutzia hybrid Lemouinei*, *Rubus delicious*, and sprays of the handsome flowering *Rhododendron Maaglesii*.

A group of new particularly-flowering pink "Diamond" was shown by Mr. B. LADHAM, Shirley Nurseries, Southampton. The flowers were pale, probably due to fastening them. Some profusely flowered plants of *Phlox acrona* provided an abundance of colour, which rather spoiled the effect of the Pinks.

From Sir Wm PEARSON, Bart., Paddockhurst, Sussex (gr. Mr. F. Capp), was exhibited a group, including some plants of a good strain of *Gloxinias*, and sprays of *double Pelargonium* flowers of new and original varieties, interspersed with *Ferns* (Vote of Thanks).

MESSRS. A. W. YOUNG & CO., Stevenage Nurseries, Herts, also contributed a group of *Gloxinias*. The cold winds had affected injuriously all such exhibits on this occasion (Bronze Bankian Medal).

ROSES from Mr. MORLEY of the Canterbury Nurseries made an extraordinary display, the best that has been shown from this establishment during the present spring. Ten large boxes, containing a dozen blooms each, were repaired; and there were three groups of *Roses* with long stems, staked in bottles, and interspersed with the boxes, which relieved the monotony of these. A considerable number of varieties of *Teas* and *Perpetuals* were included (Silver-gilt Flora Medal).

A grand display of *Marchal Niel* *Roses* was made by Mr. J. WALKER, Thame, Oxon, who had about five dozen excellent blooms (Silver Flora Medal).

MESSRS. W. PAUL & SONS, Waltham Cross Nurseries, Herts, were splendidly represented by a group of *Rose trees* in pots staged upon the floor of the hall near the entrance-door. All of the plants were fresh-looking and healthy, and many of them carried exceptionally large blooms. The following are standards, were very interesting, *Madame Camille*, *Madame Duke*, and *Duke of York*. Of dwarfier bush kinds there were *Jeannie Dickson*, *Duke of Edinburgh*, and many other varieties. Some out blooms of the variety *Marchal Niel* were of exceptional size and quality (Silver-gilt Flora Medal).

MESSRS. W. CROFTON & SONS, Highgate and Barnet Nurseries, staged a group of herbaceous and other plants, for which a Bronze Bankian Medal was awarded.

From Messrs. DACI & SONS, Chelsea, were contributed first-class specimens of the following plants:—*Sambucus phytolacca aurea*, *Andromeda japonica variegata*, *Trillium grandiflorum*, *Trollius europaeus*, *Geum maritimum*, *Phlox canadensis*, *Rhododendron Fortunei* var. *Mrs. Chas. Butler*, *R. canaliculatum ochroleucum*, several species of *Primula* and *Pulsatilla*, also *Rosa* & *Cornus*. From Mr. P. H. PEARSON, Margate, similar to the previous one, but red in colour. A good batch was included of the pretty little *Iris cristata*; it grows about 4 inches high, and has pale blue flowers suitable for planting upon rock-work (Silver Flora Medal).

An Award of Merit was recommended to Messrs. BARR & SONS, King Street, Covent Garden, for *Trollius mandchuricus*. This is a very tall-growing *Trollius*, with deep-coloured flowers than *T. europaeus*.

Messrs. JNO. WATERER & SONS, Ltd., Bagshot Nurseries, Surrey, exhibited a magnificent *Rhododendron* named *Pink Pearl*. The trusses of flower were large, and the blossoms about 1 inch across, and of a very bright, rosy-pink in colour, the upper petal moderately marked with brown. Leaves were very large, but stout. The flower-lads before opening are very deep in colour (Award of Merit).

R. I. MEASURES, Esq., Ladywood (gr. Mr. W. Woodin), exhibited a bloom of *Phloxbotanica speciosa*.

Messrs. KELWAY & SONS, Lampport, Somerset, showed a collection of blooms of *TREE PEONIES* in variety, and was awarded a Silver Crest Medal.

A First-class Certificate was awarded to a handsome *Fern*—*Anemia rotundifolia*—shown by Mr. W. BELL, New and Rare Plant Establishment, King's Road, Chelsea. The species of *Anemia* produce a branched panicle (superficially similar to those of an *Aspidium*), containing the essential organs, being therefore absolutely independent of the foliaceous fronds. The species exhibited had about twenty irregular, angular pinnae, of round shape, upon each frond, and the midrib of the frond beyond was barren, as is common to the genus. It is a handsome dwarf-growing fern of light, rather spreading appearance, and the young fronds are beautiful.

The plants from the Royal Gardens, Kew, were remarkable for their floriferous character, consisting as they did of *Rhododendrons*, *Pyrus*, &c. The *Rhododendrons* were *R. kewense* = *R. Hoekeri* × *Griffithianum*, with large rosy flowers, set in loose cymes; *R. hododendron*, with snow-sprays from Yunnan, with flesh-colored segments; with a small patch of crimson spots on the upper segment, five or six flowers on a corymb, and furnished with small smooth leaves; *R. Smirnovii*, rosy-purple and large-flowered, with leaves downy on the under side; *R. Yaseyi*, light-colored small flowers, in numerous sets, almost leafless; *R. Kewensis*, with white blooms slightly flushed and tinted with rose; *R. cinnabarinum*, from Sikkin, tubular, scarlet-and-yellow, campanulate flowers in bunches; *R. Lucombei* = *Fortunei* × *Thomsoni*, flowers bright crimson, and large in size. Another form of *R. cinnabarinum* had flowers of pure crimson, and a much more expanded, reminding one of a *Lagerflora*. *Prunus Schiedackeri*, *P. Ringo*, *Amelanchier alnifolia*, very pretty; *Ribes speciosum* (*R. Fuchsoides*), *Spiraea media*, *Cytisus purgans*, &c., were likewise shown.

Tulips formed a considerable part of the subjects staged at this meeting. The collection of Messrs. BARR & SONS, King Street, Covent Garden, could be seen various forms of the florists' Tulips in their breeders and broken forms. Breeders were represented by Sulphur and Golden-ender, bizarres, Philip I., bybtemens; Kate Connor and Medley; roses—among the best among the most beautiful; and the unbroken flowers of rectified varieties they had of bizarres, Dr. Hardy and Sir Joseph Paxton, varieties which have held their own for nearly half a century past, and it is very probable will remain undebated in the next fifty years. James Wild, Colport, almost destitute of any feathering; Victoria, George Haywood, and Lord Lilford. Bybtemens were represented by Mrs. JACKSON, both feathered and flamed; roses by Industry and Annie McGregor. Of the so-called Darwin treelers, nearly every one of which has the black base peculiar to *T. gesneriana*; Flambeau, deep red; Hecla, dark bronzy-crimson; Glow, deep crimson; Lovelocks, deep red, with a few bright yellow spots; a fine flame of slaty purple; White Queen, cream and yellow tinted with rose, very attractive; the least, very dark, the shining dark Maroon, almost black; and Bronze King, golden-bronze.

Then, of what are termed cottage Tulips—varieties of varying markings, may be mentioned, also-called, red-brush with a white base; Golden Beauty, also known as Bouton d'Or; Goldkate, flaked with gold on an orange-searlet ground; Gesneriana spatulata, crimson-scarlet; macropodia, deep scarlet, &c. Bine King and Marriage de ma Fille represented the late double varieties, and the gorgeous Parrot types were seen in the Large Yellow, Crimson Beauty, and Perfection (Silver Flora Medal).

Messrs. JAMES VEITCH & SONS had a large bank of flowers, including many forms of the Tulip. Species were represented by Cornuta, Fulgida, Florentina, Elegans, alba retroflexa, Deltieri, and Vilgini. A few of the double white roses were also shown. Large, Prince of Austria, large orange-red; Rosa Mundi, Violet Gem, bronzy-maroon with crimson shading; Diamond, bright rose; and Golden Eagle, lightly feathered with scarlet. Also the following double varieties: Earl of Leicester, yellow-flamed with orange-red; Duke's Barden, deep red, shaded with gold; Rose Blanche, a very fine double white; Blanche Rosette, flaked and marked with pink and deep rose; Le Matador, brilliant crimson; Queen of the Netherlands, flamed and daked with pink; and Marriage de ma Fille, striped. Some very fine

Parrot varieties were included in this collection, such as Marie Grand, lutescens, Perfektus, and Café Rone, in all of which yellow and orange predominated; Admiral of Constantinople and Cramoise Brillante represented the scarlet and crimson varieties (Silver Banksian Medal).

Messrs. KEELE & CO., Haarlem, had White Lady, yellow lady, and a slight yellow flame on white; and Elegant Lady, which striped with crimson.

Mr. B. LABRANS, nurseryman, Shirley, Southampton, had Flava, a large pale yellow form.

Orchid Committee.

Present: Harry J. Veitch, Esq., in the Chair; and Messrs. Jas. O'Brien (Hon. Sec.), E. Hill, De B. Clawshay, H. M. Pollett, J. Gabriel, W. H. Young, F. J. Thorne, H. J. Clapman, T. W. Bond, C. Pilcher, W. Cobb, J. Douglas, and H. Williams.

Messrs. Jas. Veitch & Sons, Ltd., Royal Exotic Nursery, King's Road, Chelsea, staged a superb group which secured for them a Silver-gilt Flora Medal, an honour seldom accorded to exhibitors. Among the most prominent in the group, which consisted of uniformly fine-grown and well-flowered specimens, were several plants of their fine hybrid *Lelia* × *Latae* (*cinnabarina* ♀, *purpurata* ♂) which have markedly improved since we last saw the plants. The flowers were of a clear lemon-pale, slightly tinged with rose, with rich purple tints to the lip, the yellow tinged with reddish purple, all the varieties being alike attractive. The same term may be applied to the kindred *Lelio-Cattleya* × *Hippolyta* raised by them, the prevailing colours of which are Indian red; the plant was also well shown (*Lelio-Cattleya* × *Ascania* C. Triana-♀, L. Sandhills ♀), and *Lelio-Cattleya* × *Philo* (*Mossie* ♀, *nicolor* ♂), were likewise shown. The group contained small lots of the handsome *Dixa* × *Veitchi*, *Dendrobium Phalaenopsis Schroderianum*, *Cattleya Mendeli*, and other *Cattleyas*; some fine *Ondotoglossums*, *Oncidium sacrodes*, O. Marshallianum, and O. concolor; *Coleogyne pandurata*, *Cypripediums*, &c.

Messrs. HENRY LOW & CO. (Ld.), Exeter, received a Silver Flora Medal for an excellent group in which were a grand white *Cattleya Gaskelliana alba*, perhaps the largest white-flowered form of *C. labiata*; a very fine *C. Mendeli*, of which *C. M. majestica* and *C. M. fabriata* were remarkably good; *Phalaenopsis Schlegelii*, *Phalaenopsis Schlegeliana*, *Lelia purpurata* in splendid forms, *Coleogyne pandurata*, fine panicles of *Dendrobium Benseana*, and other *Dendrobiums* and *Ondotoglossums*, of which O. *Andersonianum* splendens was a grand form very richly colored (*Cypripediums*, &c.).

Messrs. S. WILLIAMS & SON, Upper Holloway, staged an effective group, in which *Cattleya Mendeli* was well represented, these named "aura" and "amona" being specially distinct; in the group were also many good *Chlorodes*, C. *Skinneri*, *Lelia purpurata* in fine examples; *Erantios Leonis*, *Ara aurantiaca*, *Cypripedium* × *Calanthis*, C. × *Hammanii*, *superciliosum*, *C. corymbosa*, *Chambriferanum*, &c. Mr. G. BRIDGE, C. Box II. C. *Maestriatum*, *venustum*, a number of *Calathea Sanderiana*, some good plants of *Dendrobium Devonianum*, and D. *thyrsiferum*, and a single plant of the yellow-tinted *D. Dalhousianum luteum*; *Miltonia spectabilis*, *Oncidium concolor*, and a good selection of *Ondotoglossums* (Silver Flora Medal).

Mr. H. SHER, Esq., The Grange, Wallington (gr. Mr. Cummins), had a fine group of the showy *Cattleyas*, for which his collection is noted, most of which were beyond the average in point of beauty, that form of *C. Mendeli* named "Her Majesty," being a grand flower, with a rich carmine-crimson colored lip. Mr. Sher's group contained besides these, the singular-looking *Bulbophyllum sacroculatum*, bearing three spikes of its remarkable flower; *Cirrhopetalum elegantulum* (Botanical Cert. fide), *Oncidium unicornis*, and other pretty and singular species. For the group a Silver Flora Medal was awarded.

WALTER C. WALKER, Esq., Percy Lodge, Winchester Hill (gr. Mr. George Craig), was also awarded a Silver Flora Medal for a very bright and fresh-looking group of *Cattleya Mendeli*, C. *intermedia*, and other *Cattleyas*; *Lelia purpurata*, L. *grandis*, and L. *Boothiana*; and fine forms of *Oncidium Marshallianum*, O. *concolor*, and O. *variosum* (Regis); some good *Ondotoglossums*, among which O. *virgatum* and O. *veitchii*, the sepals bearing one or two distinct brown blotches.

Messrs. CARP & SON, Tunbridge Wells, received a Silver Banksian Medal for a small group in which were two splendidly flowered specimens of *Oncidium caudatum*; one C. C. *Walshii* and one C. *philippense*.

Mr. B. CHANTRY, Esq., 25, Bedford St., Sevenoaks (gr. Mr. S. Cooke), showed *Ondotoglossum Andersonianum Bogardianum*, one of the largest and best forms yet seen. The large yellowish-white flowers were heavily blotched with dark red (Award of Merit).

SIR FREDERICK WYLES, Clare Lawn, East Sheen (gr. Mr. F. C. Carr), Esq., 22, Elm Terrace, Tunbridge Wells (gr. Mr. J. H. Huxes), showed *Lelio-Cattleya* × *Hippolyta*, *Dulceto* variety, with a fine inflorescence of rich Indian-red or reddish-orange coloured flowers, with purplish-crimson lip (Award of Merit).

Mr. ERNEST DUNN, Bank House, Acreington, showed

Cypripedium × *bellatulo-venularium*, with handsome white flower tinged with rose, and densely spotted with purple—in a great degree resembling *O. Lepiciumum* (Award of Merit). Mrs. BIGGS BURY also showed a form of O. *Andersonianum*, and a tricolorful *Dendrobium Wardianum*.

THOS. STATER, Esq., Stand Hill, Whitefield, Manchester (gr. Mr. R. Johnson), sent *Lelia purpurata alba magnifica*, a large white form, with rich purple tints to the broadly-expanded lip.

J. FORSTER ALCOCK, Esq., Exhams, Northchurch, Herts, showed a fine *Cattleya Schilleriana*, and *Cypripedium viridescens* (C.) with greenish-yellow flowers spotted with brown.

Mr. J. MITCHELL, Boxley Heath, showed a large-flowered *Cattleya Mendeli*.

FRODO BEECHER, Brunnenhof, Riesbach, Zurich (gr. Mr. Schlich), sent the rare and singular *Oncidium Warneri*, with purple-tinted petals, and bright yellow lip (Botanical Certificate); also a splendid variety of *Vanda lamellata* Boxall, and *Houlletia Lantieri*, a very nearly ally of *H. tigrina*. The Marquis CAMBES, Bayham Abbey, Kent (gr. Mr. A. Methven), exhibited *Cattleya Mendeli* with seven flowers on one spike.

R. BROOMAN-WHITE, Esq., Arddaroch, Garrochhead, sent *Ondotoglossum Andersonianum pulcherrimum*, a rose-tinted, purple-blotched variety; O. *aucidum*, previously certified by me; and two other specimens of the same.

C. L. S. ISGRAE, Esq., Ebbotshouse, Godingham (gr. Mr. T. W. Bond), showed *Cattleya* × *Rajah* (Triana × *Marszewiczii*), and *Lelio-Cattleya* × *Sir Wm. Ingram*.

R. I. MEASURES, Esq., Lymington, Rogate, Sussex (gr. Mr. Woodin), showed his new *Cypripedium* × *Chapmani magnificum bellatulo* (Curtis), a superb large flower, with broad white petals, densely spotted with purple; massive upper sepal white, tinged with green in the centre, and with numerous dotted purple lines; and fine purple labellum—the darkest in colour, and best of its section (Award of Merit).

Messrs. F. SANDER & CO., St. Albans, arranged an effective group of *Cattleyas*, *Dendrobiums*, &c., the chief attraction in which was the massive *Cypripedium* × *Oakes Aimes* (*Rothschildianum* × *ciliolare*), which gained a Gold Medal at Hamburg. The flowers resembled C. × *Mansionium*, but the broad sepals were smaller, and especially the lip. Messrs. SANDER also showed *Masdevallia Chesterfonti*, *M. bella*, M. *Chimera*, M. *Benedicti*, *Bulbophyllum Lobbia*, *Maxillaria Sanderiana*, *Miltonia vexillaria*, *Chelonensis*, &c.

H. J. HARRIS, Esq., Bowden Hill House, Chippenham (gr. Mr. Jas. Panten), sent *Ondotoglossum Pescatorei*.

MATTHEW S. COOKE, Esq., Kingston Hill (gr. Mr. Buckell), showed a fine specimen of *Masdevallia Hartmanni*.

E. BOSTOCK, Esq., Tixdale Lodge, Staffordshire, showed ten varieties of *Lelia purpurata*, and several *Cattleya Schroderae*.

Fruit and Vegetable Committee.

Present: Philip Crowley, Esq., Chairman; and Messrs. F. R. Rivers, J. Cheal, Geo. Bunyard, J. H. Veitch, A. A. Barron, A. H. Pearson, W. J. Empson, A. Dem, Jno. A. Laing, W. Bates, W. Farr, G. H. Sage, Geo. Wythes, Jas. Smith, H. Balderson, Geo. T. Miles, F. Q. Luce, G. W. Cummins, Geo. Reynolds, G. Norman, J. Willard, and R. Wyfe.

Mrs WINGFIELD, Amphill House, Beds (gr. Mr. Empson), showed a nice collection of vegetables, including several varieties of Peas as grown in pots, and as dishes. The former were Carter's Lightning, a very early sate, and Carter's Forcing, somewhat later, but with more and better pods; Radishes in several varieties were very tempting; Potatoes, in two varieties; Cucumbers, also two, and both excellent, viz., Rockfords' Market and Blenheim; some capitata Artichokes, new Early Milan Turnips, several heads of Broccoli, Lettuces, Leeks, Earliest of All Tomatoes, a small but heavy-creeping variety (Knight's Silver Medal).

Earl Percy, Syon House (gr. Mr. G. Wythes), showed eight fruits of Hale's Early Peach, well coloured; and a large number of ripe fruits of St. John and Brown Turkey Figs.

Mr. RUSSELL, Hatfield, Metchley Farmhouse, showed a Strawberry named Early Giant, nine fruits of which have weighed 10½ oz., and some have been gathered weighing more than 3oz. each. The fruits of the first picking are much grooved, and the later ones less so, and almost of a conical shape. It is a fine looking fruit.

Apple Competition. The 1st prize went to Mr. J. C. TALLOTT, Bryn St. Edmunds, for Court Penda Plat; and the 2nd to F. C. CARR-GOM, Esq., Farnham Chase (gr. Mr. A. J. Reed), for the small-fruited Fine Golden Chip. The competitors in this class were naturally very few.

The Lecture.

The well-known mycologist, Mr. GEO. MASON of Kew; initiated his hearers into the mysteries pertaining to the life history of certain minute fungi, causing disease in plants, particularly of a few specimens that were taken as types. Each of these was illustrated by means of lantern slides, which helped greatly to render the lecture more easy a grasp.

The great fact that was insisted upon by Mr. Mason, and which has been reiterated in the *Gardener's Chronicle*, was the importance of preventive measures, compared with which attempts to cure plants already attacked are absolutely worthless. When a fungoid disease is discovered upon the epidermis of a plant, the mycelium has, in many cases, already spread underneath, and has

obtains a footing among the plant-tissues. When the epidemic has been broken, the disease has reached the last stage in its existence, viz., the fruiting stage, and has thrust its parts into the light in order to effect the diffusion of the spores. The first of the moulds illustrated was that of the *Rossmundia*, a kind of white mould, which causes the leaves to rot. The coral-cluster fungus comes to a dead wood, a species of fungus that attacks orchids, the *Peronospora* which is very destructive to forest trees, the *Peronospora* upon Vines, smut in Oats, brown mildew of Vines, juniper fungus which in another stage produces the cluster-rot upon Pear leaves, spot in Orchids, smut on flowers, and the *Claviceps*. The coral-cluster fungus comes to a dead wood, a species of fungus that attacks orchids, the *Peronospora* which is very destructive to forest trees, the *Peronospora* upon Vines, smut in Oats, brown mildew of Vines, juniper fungus which in another stage produces the cluster-rot upon Pear leaves, spot in Orchids, smut on flowers, and the *Claviceps*. The coral-cluster fungus comes to a dead wood, a species of fungus that attacks orchids, the *Peronospora* which is very destructive to forest trees, the *Peronospora* upon Vines, smut in Oats, brown mildew of Vines, juniper fungus which in another stage produces the cluster-rot upon Pear leaves, spot in Orchids, smut on flowers, and the *Claviceps*.

THE ROYAL NATIONAL TULIP.

MAY 12, 13.—THE ANNUAL EXHIBITION OF THE Southern Section of this Society took place in the corridor of the Royal Botanic Society's Gardens, Regent's Park, on the above dates. It served to demonstrate that as far as exhibition Tulips are concerned, their culture in the south for show purposes is not an very restricted scale. With the exception of Messrs. Burr & Son, and Mr. A. D. Hall of Wye, Kent, no southern grower was represented, unless Cambridge can be considered in the southern district; for there were two exhibitors from that town. With few exceptions all the best flowers came from Manchester, for it was the treasurer and secretary of the Society, both of whom reside near Manchester, who made the chief display; but their flowers were immature, and showed signs of having been buried in heat. So far, there did not appear to be any evidence of anything like a renewed interest in Tulip-growing in the south.

May is the season of the Tulip—the brilliant and dazzling flower which has glorified our parks and gardens for weeks past. The Jesuit poet Ruyss said of the Tulip—
"Six gaudy leaves a painted cup compose."
On which kind Nature every day bestows;"

and the florist has followed Ruyss, for he has made six petals neither more nor fewer, and six stamens—a stamens to each petal—the equipment of a perfect flower. Purity in the base, whether it be the yellow base of the bizzarro, or the white base of the rose, is the first consideration. It is the consequence, and the stamens upon which the bold black anthers rest, must be as pure as the ground colour. The southern growers of the Tulip especially, have always put purity in the forefront of their estimate of a variety, it is a property which has been gained after very many years of careful work with seedlings, and the result is of importance. Then the corsors who know their work require that the petals be broad, smooth at the edge, level as possible on the top, and of fine polished surface and substance, and so bending upward from the base as to first form a good shoulder. The featherings of colour in the case of the feathered flower should be seen in beautiful styles of pencilling round the edge only of the petals, the remaining surface should be free from colour. In the case of the flamed flower the pencilling on the feathered edge is still indispensable, and in the case of a finely marked variety, it should be joined by "bold beams of colour, that rise like fire flashes up the petal centre, and strike into the pencilling of the edge with sharp tongues." It is well that the high properties of Tulips be recited, as, judging from some samples seen at the meeting of the Royal Horticultural Society on Tuesday, these properties appear to be not sufficiently known.

The leading class was for twelve rectified blooms, two feathered and two flamed in each class. Mr. C. W. NEEDHAM, the Treasurer, who resides at Royton, near to Gildham, was 1st, having, of bizzarros, H. Lowe, and Mastertice, feathered; Sir J. Paxton, and Samuel Barlow, flamed; of bizzarros, Trip to Stockport, and Adonis, feathered; Chancellor, and Adonis, flamed; roses, Lea, and Julia Farnese, feathered; Mabel, and Annie McGregor, flamed. The finest bloom in this collection was Trip to Stockport, and it was selected as the premier feathered flower in the whole show. Samuel Barlow and Sir J. Paxton were finely marked, and Mrs. Lea in good character. Mr. J. W. BENTLEY, the Secretary, Stockhill, Castleford, Manchester, was 2nd, his blooms being small, and wanting development. Of bizzarros, he had Sir J. Paxton and Magnum Bannum, feathered; Mastertice and Samuel Barlow, flamed; byblymens, Chellston Beauty and Mrs. Cooper, feathered; and Annie McGregor, feathered; roses, Harlow, and Count de Vergennes, feathered; Rose Constant and Mabel, flamed; Mr. A. CHATER, Cambridge, was 3rd. He showed some of the varieties raised by Mr. Richard Heady many years ago, such as Sarah Heady, feathered rose; Richard Heady, feathered bizzarro; and Black Prince, flamed bizzarro.

In the class for six varieties there were also three exhibitors. Mr. NEEDHAM being again 1st, having of bizzarro, John Hopworth, feathered; and Sir J. Paxton, flamed; bybly-

mens, Trip to Stockport, feathered; and Talisman, flamed; roses, Mabel, feathered; and Annie McGregor, flamed. Mr. J. W. BENTLEY was 2nd, showing much the same varieties in the preceding class; and Mr. CHATER 3rd.

In the following class for six varieties, exhibitors in the previous one being barred, Mr. A. D. HALL, Wye, Kent, was 1st, showing larger flowers than the northern men. He had of bizzarros, William Annibal, feathered; and Sir J. Paxton, flamed; byblymen, Adonis, feathered; and the same flamed; roses, Madame St. Arnaud, feathered; and Mabel, flamed. Mr. H. B. GREY, Cambridge, was 2nd.

The class for three feathered Tulips, one of each class, is always an interesting one, and the feathered flowers are not nearly so numerous as the flamed ones. Here Mr. BENTLEY was 1st, with bizzarro, William Annibal; byblymen, Elizabeth Pegg; rose, Mrs. Lea 2nd, Mr. NEEDHAM, with bizzarro, Mastertice; byblymen, Adonis; and rose, Modesty. Mr. A. D. HALL was 3rd.

With three flamed flowers, Mr. HALL was placed 1st; he had bizzarro, Dr. Hardy, very bright; byblymen, William Bentley; and rose, Annie McGregor. Mr. BENTLEY came 2nd, with bizzarro, Sir J. Paxton; byblymen, Duchess of Sutherland; and rose, Sarah Heady. Mr. NEEDHAM was 3rd.

Prizes were offered in memory of the late President, Mr. Samuel Barlow, for the best pair of rectified Tulips, one feathered and one flamed. Mr. A. D. HALL was 1st, with bizzarro, William Wilson, feathered; and Sir J. Paxton, flamed, both in good character for the season. Mr. J. W. BENTLEY was 2nd, with bizzarro, Mastertice, feathered; and Sir J. Paxton, flamed. Mr. C. W. NEEDHAM was 3rd.

As premier flowers, the following were selected as the best feathered Tulip, Trip to Stockport; flamed, Sir J. Paxton, the latter shown by Mr. BENTLEY. The only collection of ninety blooms of florists' Tulips, in thirty varieties, came from Mr. J. W. BENTLEY, a very meritorious one for the year. It consisted of feathered and flamed flowers and breeders of the three sections. The blooms were arranged in earthenware bottles, but scarcely showed themselves to the best advantage. The best collection of the same, similarly shown, came from Mr. NEEDHAM. A further class for a collection came from Messrs. Burr & Son, showing a selection on their white-colored blooms, as many as sixty-three blooms of Dr. Hardy, feathered bizzarro, was in this collection, with many others, and the same firm won Mr. W. Robinson's Silver Medal for a collection of other than florists' varieties, showing a large number, Darwin breeders and Parrot varieties, these preeminently.

The self-colored breeder Tulips, which are in the transient state, had two classes set apart for them. The best six came from Mr. C. W. NEEDHAM, who had of bizzarros, Richard Yates and Storer's Seedling; byblymens, Duc d'Orleans and Camp's Seedling; roses, Mabel, and Annie McGregor, the last brilliant in colour, and so pleasing that one can desire should never pass out of the breeder stage. Mr. J. W. BENTLEY was 2nd, having of bizzarros, Sir J. Paxton and J. Goldinger; byblymens, Adonis and Jennette; roses, Mabel and Lloyd's Seedling.

Mr. NEEDHAM was also 1st with three varieties: bizzarro, Stiphur; byblymen, Adonis, and rose, Annie McGregor.

The premier breeder was rose, Mabel, shown by Mr. H. B. GREY.

In addition to their Tulips, Messrs. BARR & SON had a large collection of cut flowers, including Daffodils, to which the Gold Medal of the Royal Botanic Society was awarded; and awards were also given to Messrs. J. LAING & CO. for their 1st; Mr. C. TURNER, Royal Nursery, Slough, and Messrs. VERRILL & SONS, Chelsea, who had a collection of Tulips &c., similar to the one staged at the Drill Hall, Messrs. LAING and Mr. TURNER's collections consisted of miscellaneous flowering and foliage plants.

Obituary.

ROBERT OWEN.—It is with regret we have to announce the sudden death of Mr. R. Owen of Maidenhead, on Saturday last, the 8th inst. Mr. Owen was thoroughly well known to the Chrysanthemum world, he having raised many English seedlings of exceptional merit. Having commenced business close upon fifteen years ago, the Chrysanthemum has always been treated as a *specialité* at Castle Hill Nursery, Maidenhead; but in a lesser degree, Mr. Owen cultivated Carnations, Tuberosas Begonias, and other plants, necessary for maintaining a local florist's business. Until he commenced business for himself, Mr. Owen was a gardener, and his last situation was with G. Schwabe, Esq., in the Henley-on-Thames district, by whom it is said considerable help was afforded deceased, when it was decided he should remove to Maidenhead. Mr. Owen was only in his fifty-seventh year, and his untimely end could scarcely have been more sudden. He was at work in the potting-shed on Saturday afternoon at about 4 P.M., when he fell backwards, without the least warning, and expired within two minutes. Having been examined by his medical adviser only a

week previous to his death, an inquest was unnecessary, it being known that an affection of the heart existed. To the bereaved wife and family we tender our respectful condolences, which are shared, we feel sure, by most of our readers. Deceased was interred on Thursday at 11.30 A.M.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees — a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

The districts indicated by number in the first column are the following:—
0, Scotland; N. Principal Wheat-producing Districts — 1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S.; Principal Grazing, &c. Districts — 6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending May 8, is furnished from the Meteorological Office:—

"The weather during this period was in an unsettled condition, with frequent falls of rain over the western and northern parts of the Kingdom; but elsewhere, although a little rain was experienced about the middle of the week, the condition was generally fair and dry. Slight thunderstorms occurred in isolated parts of Great Britain—mostly during the middle of the week.

"The temperature just equalled the mean in England, N.E., but was below it in all other districts, the deficiency amounting to 4° in Scotland, N. and W., and in Ireland, N. The highest of the maxima were recorded on the 8th, and ranged from 68° in England, E., and the 'Midland Counties,' and from 69° in England, S. and S.W., to 55° in Scotland, N." The lowest of the minima were recorded either on the 4th or 6th, and ranged from 29° in England, N., 50° in Scotland, E., and 31° in Ireland, S., to 35° in England, N.W., and to 38° in the 'Channel Islands.' Sharp ground-frosts were of frequent occurrence in all the inland parts of the kingdom.

"The rainfall was much more than the mean amount in Scotland, N., and considerably in excess in Scotland, W., England, N.W., and Ireland, N.W.; but elsewhere, although the normal in Scotland, E., England, S.W., and the Channel Islands, but elsewhere there was a decided deficit.

"The bright sunshine exceeded the normal amount in all the 'Wheat-producing' districts, as well as in England, N., but showed a deficiency in all other localities. The percentage of the possible duration ranged from 47 in England, S., 42 in England, E., and the 'Channel Islands,' and to 45 in Scotland, E., to 31 in Ireland, S., 23 in Scotland, N., and 42 in Ireland, N."

MARKETS.

COVENT GARDEN, MAY 1

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal dealers, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Etc.]

CUT FLOWERS.—AVERAGE WHOLESALE PRICES.

Table listing prices for cut flowers such as Anemones, Azaleas, Bouvardias, Carnations, etc., with columns for quantity and price.

PLANTS IN POT.—AVERAGE WHOLESALE PRICES.

Table listing prices for plants in pots such as Adiantum, Aspidistra, Azaleas, Calceolarias, etc., with columns for quantity and price.

FRUIT.—AVERAGE WHOLESALE PRICES.

Table listing prices for various fruits such as Apples, Bananas, Grapes, Melons, etc., with columns for quantity and price.

VEGETABLES.—AVERAGE WHOLESALE PRICES.

Table listing prices for various vegetables such as Artichokes, Asparagus, Beans, Cauliflowers, Cucumbers, etc., with columns for quantity and price.

POTATOS.

Trade slow at following prices:—Dunbar Maincrop, 80s. to 90s.; Saxons, 75s. to 78s.; Lincoln Saxons and Maincrop, 45s. to 70s.; do, Giants, 20s. to 30s. per ton. Conary new, 11s. to 14s.; Guernsey and Jersey do., 17s. to 20s.; Malta do., 9s. to 11s.; Lisibon do., 9s. to 10s. per cwt John Bath, Wellington Street, Covent Garden.

SEEDS.

LONDON: May 12.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., write that there were but few buyers on to-day's seed market, and only a small business was transacted. The present protracted spring season being now nearly over, sowing orders for grass, Clover seeds, &c., are naturally diminishing, both in number and extent. Tares are scarce and favour sellers. Full prices are asked for Mustard and Rape seed. Rye is inquired for. The trade for Bird seeds presents no fresh feature. Scarlet Runners are in increased request. The remarkable and unusually cold weather now prevailing, and the injury done thereby to growing green vegetables, have greatly stimulated the consumptive demand for Blue Peas and Haricot Beans. The Californian Butter Beans just arriving meet with considerable favour.

CORN.

AVERAGE PRICES OF British Corn (per Imperial qr.), for the week ending May 8, and for the corresponding period of 1896, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

Table comparing prices of British Corn in 1896 and 1897, with columns for Description, 1896, 1897, and Difference.

(Carried over to p. xi)

ARUM LILY: G. H. T. The production of a spathe-like leaf is by no means uncommon, judging from the numerous specimens we receive in the course of the year.

CHAMEROPS SEED: J. C. See next week's issue.

CHYSANTHEMUM: J. C. See next week's issue.

CYRUSUS: P. laudius. What you send under this name is a fine golden-leaved variety of Thunbergia giganta of gardens (the true T. plicata). The colouring is particularly rich.

MELONS: E. A. B. We are unable to tell you, from the information that you afford us, what is the matter with your Melon plants. The age of the seed will not account for their failure to fruit; indeed, age in the seed favours abundant fruiting. There must be something wrong with the culture.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—A. T. Disa racemosa.—W. T. Ornithogalum nutans.—A. E. No numbers. Pilea muscicola, the Artillery-plant; the ovate leaf is Nubiaheekia complexa.—W. O. W. 1, Juniperus communis; 2, Lantiorhiza apifolia; 3, Cytisus racemosus; 4, Xanthoxia tatarica; 5, specimen insufficient, perhaps a Kleinia; 6, redum Sibeldi variegatum.—D. S. Lonicera tatarica.—F. F. 1, 2, Pyrus (Malus) floribunda; 3, Arnebia echioides; 4, Polanowaria officinalis.—A. S. Dendrobium fimbriatum oculatum.—E. S. W. 1, Spiraea Thunbergii; 2, not recognised, send when in flower; 3, Cytisus precox; 4, Berberis Darwinii; 5, Berberis stenophylla;—W. H. B. 1, Prunus Scheideckeri; 2, Vaccinium corymbosum.—J. J. F. Pyrus intermedia.—H. C. 1, Doronicum caucasicum; 2, Alyssum saxatile; 3, Valeriana (Centranthus) rubra; 4, Dientea formosa; 5, Iberis orreocifolia; 6, Arabis albida; 7, Hesperis matronalis.

NEW STRAWBERRY: J. Davidson.—So far as we can judge from a single fruit, which arrived in bad condition, it is a first rate variety well worth developing.

ODONTOLOSSUM CHIMONUM: A. G. S. Union of two flowers is not uncommon, particularly when growth has been rapid.

PAPAY: W. H. M. These stove evergreen fruit trees are grown more for ornament than use. Carica cudiudumarcensis flowered and fruited in an open border in the late Mr. Hanbury's garden at Clapham; but this is a species that grows on the Andes of Ecuador at a height of 9000 feet. The common Papaw, C. papaya, is, like all the species, a native of South America, although naturalised in India and other countries. A plant of this

species fruited in the Glasgow Botanic Garden in the early part of the century. Both are figured in the Botanical Magazine.

PEACH: J. B. Peach blister, caused by the growth of a fungus. Burn all the affected leaves.

PETALLESS APPLES: Ecklinville. There is, or was, a French variety, which constantly failed to produce petals; but we have not noticed it before in the Ecklinville.

PINK AND WHITE ZONAL PELARGONIUMS: S. W. Brunt, not Madame Eriant, has flowers white in the centre, shaded with pink; Dr. Nansen is one of the best whites, dwarf and free; Eriant is also a good white; Snowdrop has snow-white, very large flowers; La Rhone is a nice, pink coloured variety, of pretty good quality, vigour, and endurance; Princess Alix is an excellent clear pale rose or pink, pink large.

RICHARDIA (CALLA) ETHIOPIACA: J. W. The variegated form of this plant has long been in cultivation. It is pretty constant.

SHADING FOR GLASS: Dahlia. Home-made shading consists of sour skimmed milk, into which white has been mixed, so as to form a thin sort of paint. It may be applied with a painter's brush, either out or inside. "Summer Cloud," sold by nurseries and florists, is a useful kind of wash for the roofs of glasshouses. The best sort of shading is that made from split Bamboo fixed to rollers, which may be rolled up when the sun is not shining ardently.

STRAWBERRY FRUITS WITH MOULD: H. P. The white waxy appearance of the fruits of your Strawberry is caused by a mould similar to that of Vine-milium. It is Oidium Ebsenii, or very much like it, which also attacks Turnips. The mould doubtless originated from the leaves, which would have been affected even before the blossoms "set." It is improbable that any fungicide can be employed at this stage. It might have been possible to have done some good with sulphur at an earlier period. M. C. C.

VINES: G. B. and B. & S. The fungus attacking the Vine in each case is the well-known pest, Sclerotinia Puckeliana. The greyish mould on the leaves and inflorescence is the conidial or summer form of the fungus. The plant should be thoroughly sprayed with a solution of potassium sulphide—half an ounce of the salt dissolved in a gallon of water—to check the spread of the disease. All diseased parts should be removed, otherwise sclerotia, or lumps of spawn, are formed in the tissues. These rest during the winter, and again produce the disease in the spring. In any circumstances, the Vines should be sprayed with the above solution next spring, at intervals of ten days, at the time the leaf-buds are expanding, to prevent a repetition of the attack, as numerous fungus-spores are certain to be present in crevices of the bark, &c. G. Massoc.

CONTINUED LARGE INCREASE in the CIRCULATION OF THE "GARDENERS' CHRONICLE."

IMPORTANT TO ADVERTISERS.—The Publisher has the satisfaction of announcing that the circulation of the "Gardener's Chronicle" has, since the reduction in the price of the paper,

Increased to the extent of more than 90 per cent., and that it continues to increase weekly.

Advertisers are reminded that the "Chronicle" circulates among COUNTRY GENTLEMEN, AND ALL CLASSES OF GARDENERS AND GARDEN-LOVERS at home, that it has a specially large FOREIGN AND COLONIAL CIRCULATION, and that it is preferred for reference in all the principal Libraries.

THE

Gardeners' Chronicle.

SATURDAY, MAY 22, 1897.

THE BIBLIOGRAPHY OF THE DAHLIA.

THE short notice of "The Dahlia by Various Writers," which appears on p. 221 of the *Gardeners' Chronicle*, is a reminder of a long period of literary neglect, that a somewhat gorgeous and once highly-popular flower has had to undergo. There have, of course, been numerous articles in the horticultural press on Dahlia history and cultivation by writers specially interested in those subjects for many years past, but unless I am much mistaken no independent treatise worthy of the name has been written for a period of something like forty years. Before taking a brief survey of the bibliography of the Dahlia, it may be useful to mention that in addition to the Dahlia Conference held by the Royal Horticultural Society, there was also one held in 1889 at the Crystal Palace, under the auspices of the National Dahlia Society, primarily for the purpose of celebrating the centenary of the introduction of that flower into Europe, and the papers which were then read appeared in the Society's Report for the following year.

Having for some years past devoted a portion of my leisure to the collecting of books on florists' flowers, I have picked up from various sources a number of cultural and other treatises dealing with the Dahlia. I believe the collection to be complete, but it is possible that there may be some small insignificant works of merely local repute wanting. Many little paper-covered pamphlets on various florists' flowers have from time to time been issued, but owing to the flimsy form in which their authors have produced them, they have had but an ephemeral existence, and consequently are most difficult to obtain.

In the early part of the present century the Dahlia as a show flower occupied a position analogous to that enjoyed to-day by the Chrysanthemum, and similarly many of the novelties were of continental origin. So therefore the majority of the books, but particularly the earliest, were written by French authors.

It is beyond the scope of this article to refer at length to the contributions of such writers as those who wrote in the Journals and Transactions of the various horticultural and botanical societies at home and abroad when the Dahlia was first introduced. Cavanilles, Thoinin, Willdenow, Sabine, de Caudolle, Wedgwood, and others, have all in some way or other described the flower from a botanical or horticultural standpoint in such works as are alluded to.

The first independent treatise was that entitled *Essai sur la Culture, la Nomenclature, et la Classification des Dahlias*, by Messrs. Jacquin frères, of Paris, and was published in 1828. Two years later a second edition in a much enlarged form appeared, and besides giving between fifty and sixty pages of cultural direc-

tions, the authors supplied a descriptive catalogue of the varieties then known, classed according to their colour. This list, arranged in eleven main divisions, contains the names of 289 varieties, followed by a supplemental list of another 164 varieties, which bear no descriptions, as they had not been tested by the authors. As an example of the somewhat methodical way in which the varieties were classified, we see that Division I. comprises only white Dahlias. Then this division is sub-divided into sections:—1, Beng for pure white; 2, for ivory-white; 3, for lilac-white; and 4, for rosy-white. Divisions II. to XI. are devoted to various other colours, viz., rose, lilac, violet, purple, amaranth, crimson, red (12 sections), yellow, &c., showing that very great diversity of colour existed even in those far off times.

The next book was from the pen of Comte Leliour, whose name is frequently mentioned by English Dahlia writers as a prominent cultivator. This gentleman was Director of the Parks and Gardens of the King of France, and a corresponding member of the London Horticultural Society. His book was published in 1829, under the title of *Mémoire sur le Dahlia et sur sa Culture*. The Comte reviews much of the literary matter that had previously appeared in other works, both English and foreign, and deals liberally with the details of cultivation, without, however, adopting the very common practice of swelling the size of his volume with a long list of varieties at the end.

Most lovers of the Dahlia have either seen or heard of the *Annual Dahlia Register*, with its inordinately lengthy title and numerous coloured illustrations, of which there are about fifty in all. This was published in 1836 in London, and was no doubt regarded at the time as an *édition de luxe*. The intention was to make it an annual publication, but the price at which it was issued—£1 10s.—seems to have been prohibitive, notwithstanding the enthusiasm of the growers, and it never got beyond the first volume. The literary matter consists chiefly of dealers' catalogues, show reports, and a few odd articles on various subjects connected with the flower. The book, however, will long remain of value to the student of Dahlia literature, and the plates have an historic interest for those who are concerned with the evolution of their favourite. The style and get-up of the annual *Dahlia Register* certainly speaks much for the enthusiasm and hopefulness of its compiler, who is described as an amateur.

In 1838 Sir Joseph Paxton published a handy little cloth-covered book called *A Practical Treatise on the Cultivation of the Dahlia*, and this was in the following year translated into French, and issued under the title of *Traité pratique de la Culture du Dahlia*. The next book was also French, and came out about 1840 in the *Bibliothèque du Jardinier*. It was written by Pirelle, and its title was simply *Dahlia*. The same work, identical in every respect save the cover, appears to have been published by Pirelle, in 1840, under the title, *Traité Spécial et Didactique du Dahlia*, and then in 1841 Pirelle again appears on the scene with one called *Recue des Dahlias en 1840, ou Supplément au Traité des Dahlias*.

In 1845 yet another book, similar in form and size to the three preceding, and, like them, published in Paris, was written by Augustin Légrand. This was called, *Le Dahlia: Histoire et Culture détaillée*, and of this a second edition, bearing the title, *Manuel du Cultivateur de Dahlias*, revised and corrected by Pepin, was

published in 1848. It is rather curious to note that while in the earliest French books the varieties mentioned in the descriptive lists were mainly of continental origin, those enumerated in the later ones contained a large percentage of varieties bearing undoubted English appellations, and these often accompanied by the raiser's names.

Probably none of the Dahlias then grown are known to modern cultivators, but it may be interesting to mention that in the last-named work, that by M. Pepin, the English raisers represented were Keynes, Brown, Drummond, Harrison, Girling, Kimberley, Proctor, Salter, Heale, Mitchell, Turner, and several more; and in addition to these there are names of others given which show that Dahlias were then being raised by German growers.

In *Tyus's Popular Flowers*, one of the series was devoted to the flower under notice, but it was only a small sixpenny pamphlet of a few pages, and its scope was rather restricted; its date of issue was 1844. In another series of gardening books called the gardeners' monthly volume, there appeared, in 1847, a volume entitled *The Dahlia, its Culture, Uses, and History*, by George W. Johnson and G. Turner; and from it I learn that Mr. Turner gave to the public in the preceding year his *Practical Observations on the Culture of the Dahlia*. Whether these observations were issued in a separate form, or appeared in some other horticultural publication, it does not say; nor do I know, for although no effort or expense has been spared to trace the "observations," the result has been far from satisfactory, and the only information gained is, that it is believed they formed the preface to Mr. Turner's trade catalogue of Dahlias for that year. In the treatise devoted to the Dahlia which appeared as one of the gardeners' monthly volumes, a brief sketch of the literature of the flower is given, beginning with Cavanilles' article, and M. Thoinin's memoir in the *Annales du Muséum d'Histoire Naturelle* (1804), which is also in my collection, and in which a coloured plate is given of three varieties then known. They are all singles, the double form being then no doubt non-existent. Other references are also made to various contributions that appeared in the *Horticultural Transactions*, the *Gardeners' Dictionary*, and different botanical publications, but curiously enough there is not a single reference to any of the French publications to which attention has been called by me in the earlier part of this paper.

The late Dr. Hogg, in 1853, published *The Dahlia: its History and Cultivation, with Descriptions of all the best Show-flowers*. From a literary and artistic point of view, this book unquestionably ranks next in importance to the *Annual Dahlia Register*, for it is of the same size, although less bulky, and it contains eight large coloured illustrations, and is a well-printed, historical, and cultural hand-book, that no doubt was regarded as a standard work in its day.

Mr. Shirley Hibberd, who contributed much information of a valuable nature on the occasion of the two Dahlia Conferences held in 1889 and 1890 respectively, was the author of a little pamphlet, with a coloured frontispiece, in 1857. It was one of his series of "Garden Favourites;" and then occurs a great blank in the independent bibliography of our subject, which extends over four decades.

American gardening literature reveals little or nothing in the shape of Dahlia literature in

separate form, except a pamphlet published last autumn by Lawrence K. Peacock, the Secretary of the recently-formed American Dahlia Society; and a pamphlet issued early in the present year, being Bulletin 128 of the Cornell University, Horticultural Division, entitled "A Talk about Dahlias, by Wilhelm Miller," which is accompanied by a sixteen-page Inventory of the single, pompon, large-flowering, and cactus varieties grown at the Cornell Experiment Station during the past year. These, and the publication of *The Dahlia by Various Writers*, seem to point to a revival of literary interest in the flower, and cannot fail to be productive of beneficial results. C. Harman Payne.

NEW OR NOTEWORTHY PLANTS.

BOLBOPHYLLUM PFILOGLOSSUM, *Wendland and Kranzlin (Barbiger)*.*

This curious *Bolbophyllum* was discovered by the late Johannes Braun. His last collection reached Europe in tolerably good condition, and was purchased by Mr. Hermann Wendland, who flowered the plant for the first time in 1896, at Herrenchauzen, near Hanover. I am indebted to him for fine materials, i.e., a splendid raceme, and a sketch of the plant. About the affinity, it is clear at the first glance that it belongs undoubtedly to the little group of this genus, of which *Bolbophyllum barbigerum*, Lindl., is the first; and *B. calamarium* is, I believe, the best known representative. It is, however, easy to distinguish it from those species and others of the same affinity, by the want of horns on both sides of the auricle, by the well-developed side-lobes of the lip, and by the long purplish hairs covering the whole margin from the very base to the top. In the other species, the hairiness is confined to the anterior part, or at least a smaller area of the lip, and in all the other species side-lobes are totally wanting. The flowers are smaller than those of *B. calamarium*, and of green colour, spotted with purple; they are somewhat larger than those of *Bolbophyllum sibiricum*, Lindl. Mr. Wendland, who has seen the flowers opening, says that the irritability and the movements of the lip are quite the same as in the *Megaclinium*, or Frog Orchids, and that they make the same striking impression on the beholder. *F. Kranzlin*.

CULTURAL MEMORANDA.

LILACS.

WHERE a large number of Lilacs is placed annually it is best to have two batches of plants, each batch being sufficient in number for one year's requirements. The plants used then only be forced every alternate year, which to a great extent will reduce the amount of labour necessary to prepare them. In cases where there is but one batch, the plants require early attention, and should be cut back to three or four buds on the previous year's wood, after which they may be placed near the glass in a temperature

* *Bolbophyllum pfioglossum*, Wendland et Kranzlin (*Barbiger* rev.).—Caulis primario longe proterente 1-2 mm. diam., caulibus secundariis (bulbis) cataphyllis quibusdam ovatis basi involutis, subtetragonis, ovatis obtusis 2 cm. altis, 15 cm. crassis, monophyllis; folio o basi cuneata linearis-ligulato obtuso bilobato ad 10 cm. longo ad 2 cm. lato; racemo folia excedente tenui ad 25 cm. alto subramante; squamis arete adpressis ovatis reflexis; bracteis paleaceis triangulis quatuor duplo longioribus acutis; sepalis triangulis acutis. Lateralibus in aestivatione fere rectangularibus; connectivis cartilagineis viridibus purpureo adpressis; petalis o basi multo latiore subito contractis linearibus sepaliferis equantibus, labelli fusco-purpurei lobis lateralibus porcis rotundatis anticis acutis satis longe fimbriatis, lobo intermedio linearis-oblongo subperforato crasso supra rima longitudo in medio lato margine pilis mucronatis hirsuto; gyno-stomio crasso perforeto, dentibus utriusque cilde abbreviatis. Sepala 6 mm. longa, labelium paulo longius, ovarium crassiusculum turbatum altitud.

Madagascar, loc. Jch. Braun vir beatiss.

of 50°, where they may be thoroughly syringed occasionally. The plants will start away freely from the base, and if requisite they may be repotted into pots of a slightly larger size. Grow them sturdily, avoiding all means a high temperature and weak spindly growth. When they have made sufficient growth, gradually harden the plants, and finally plunge the pots up to the rim in a sunny position.

If there are two lots, good results are more certain, and the plants after flowering need only be hard pruned, and planted out on a well-prepared border, making the soil about the roots firm, which will induce a solid growth, which, if not strong the first year, will, by due attention to pruning, &c., be succeeded the following season by strong wood in a good state for flowering. Thus, if there are two good batches, the plants will need attention less early, and house room is not required; besides which, the plants are more certain to give satisfaction.

AZALEA INDICA.

As soon as these plants have done flowering, give the foliage a thorough syringing with a solution of Oshburn Compound, to destroy any thrips, &c. The operation should be done in the open, so that no thrips be dislodged from the plants into the house. If convenient, the plants may be fumigated, but even then it is good practice to thoroughly wash the plants with some insecticide. The seed-pods should be removed, and the plants stood in a warm structure to encourage an early free growth. Repot any that require more root-space as soon as new growth commences, using sweet fibrous peat and sharp grit. The fresh pots should be clean and well drained, and the roots in a moderately damp condition. Disentangle the outside roots with a pointed stick, and pot very firmly, taking great care to work the soil around the roots, and do not over-pot at one time. *H. Markham*.

ORCHID NOTES AND GLEANINGS.

CATTLEYA SCHRÖDERÆ.

SEVERAL varieties of this delicately-tinted and fragrant *Cattleya* come from the collection of Joseph Broome, Esq., Sunny Hill, Llandudno, who certainly gets magnificent flowers on most of the species he cultivates. Most of the flowers are of the charming Peach-blossom tint peculiar to the species, but one is pure white with a bright yellow tinge on the lip, and another is white and closely veined with light purple, the labelium having a clear orange disc. In addition to its great beauty, C. Schröderæ, which is not plentiful, has the merit of completing the chain of varieties of C. labiata, and continuing the display of them the greater part of the year.

Two very distinct varieties of *Laelio-Cattleya* × *Schilleriana*, the one with a peculiar white tute to the lip, and the other with a richly-coloured front lobe, accompany the *Cattleyas*.

ORCHIDS AT THE GRANGE, WILMSLOW.

Science and experimenting go hand in hand, and although some experiments result in failure, a sufficient number to encourage the experimenter brings success, and in any case some amount of experience is gained. Thus in the gardens of such an enthusiast as Dr. Hodgkinson, who is fond of plants difficult to grow, and who is continually endeavouring to find out their requirements, it is not surprising to come upon a large number of species which many persons grow but indifferently, among the most thriving and floriferous in the care of Mr. Moore, the gardener there. Among these may be mentioned a number of *Lælia majalis*, which produce a fine show of their large, handsome flowers annually; numbers of *Cattleya citrina*, finely in bloom; *Eulophelia Elisabethæ*, with a fine spike, and which here grows and blooms well and regularly; *Cattleya Rex* and C. *Schilleriana*, in splendid forms; and *Compretia macroclitron*, and a number of other kindred species, usually considered fragile, here thriving and flowering well.

In the cool-houses a pretty display was remarked of *Odontoglossum*, *Madevalias*, and *Sophrontia*, one

magnificent variety of *S. grandiflora* bearing seven noble flowers; and other interesting species. Specially good were the forms of *Odontoglossum Cervantesii*, including the rose-tinted O. C. *Ilacium*, O. *Rossii majus*, and the varieties of O. *cispura*, of which one handsome variety had the sepals furnished with heavy reddish-brown blotches, and resembling O. C. *Triana*.

In the intermediate-houses a good show was made with *Cattleya Schröderæ*, C. *Mendeli*, *Lælia purpurata*, and other species; good plants of *Cattleya aurea*, a fine lot of strong specimens of *Odontoglossum citrosimum* about to flower well; *Miltonia cuneata*, M. *Reedii* and its white variety; many kinds of *Dendrobium*, *Arundina bamusefolia*, *Lælia cinabarina*, and the chrome-yellow-flowered *L. flava*, together with *L. cinabarina aurantiaca*, which seems intermediate between the two named; some specimens of *Vandas*, including the one known as *V. gigantea* (*Staurospis gigantea*), and a number of species and hybrids of *Cypripedium*.

In all the houses interesting species, other than *Orchids*, are grown. In the cool-house were *Darlingtonia californica*, and other singular plants; and in the warm ones, *Anthuriums* and other stove plants not likely to harbour insects—and in many ways the gardens and houses are made specially interesting.

ODONTOGLOSSUM CRISPUM.

When viewing the fine flatly-ridged forms of this species, which are now regarded as "the best type," the question is often asked—But why crispum? for it is seldom that a variety which would suggest that name appears. A noble specimen, to which the term may be applied in its broadest sense, is sent by Capt. Holford, Westonbirt House, Tetbury, Gloucestershire (gr. Mr. Chapman). The flowers are large, the segments broad, and both sepals and petals are most beautifully crisped, curled and fringed, and yet in such a manner as to add to the artistic beauty of the whole inflorescence. The sepals are banded with bright purple on the reverse side, the tint appearing also in a lesser degree in the front. Each sepal has in the inner half a cluster of brown blotches. The petals are pure white, very much cut and fringed. The labelium has a bright yellow base, surrounded by a number of cinnamon-brown spots, and a white, crimped, and fringed margin.

PROGRESS OF THE CYCLAMEN.*

(Continued from p. 318.)

Colour.—There is evidence that seminal variation as regards colours occurred at least as early as 1829, but the modern forms with large coloured flowers, according to Mr. Martin, originated in a different way, and can be traced back to the old *crisatum* and white. That preserves the crimson ring round the throat, but is otherwise an albino. There is nothing remarkable in this. Any species in nature may produce white flowers; albinism is in effect the commonest of all variations. "Giant White" is a pure albino, in which the crimson ring has been suppressed.

The modern coloured forms were obtained in the first instance by selecting forms in which the coloured ring showed a disposition to spread into the white corolla segments. The first indication would be a scarcely perceptible streak. By selection from self-fertilised plants the streak was widened into a stripe. Continuing the process, the stripes widened, and a uniformly coloured flower was obtained.

The more striking colours, such as that of "Vulcan," which is a dark crimson, were, however, obtained not by progressive selection, but amongst the progeny of cross-fertilised plants.

I learn from Messrs. Hugh Low & Co. that coloured varieties, of course when self-fertilised, come true from seed. This is in accordance with a well-known principle.†

The Butterfly Form.—This has been obtained in—

* The cultural evolution of *Cyclamen latifolium*, *Sibthorp*, "By W. T. Thibaut, Dyer, C.M.G., C.I.E., F.R.S. Read March 18, 1897, before the Royal Society.

† Darwin, *Cross and Self-fertilisation*, p. 460.

dependently by several horticulturists. The segments are partially spreading, and concave on their inner surface. One of the most remarkable is that raised by M. de Langhe-Vervaeue; it is represented in fig. 113. He informs me that "these are the products of the eleventh year of improvement." He adds: "I never crossed them with any other strain; I do not like crossing races. I prefer improving them." He has kindly favoured me with the following detailed account of the mode in which the strain has been developed and improved. I quote it in his own words:—[See also *Gardeners' Chronicle*, 1897, p. 71, fig. 19.]

"Les Cyclamen Papilio que j'ai obtenus sont issus directement des Cyclamen persicum, var. gigantum. "Il y a environ une douzaine d'années je remarquais parmi mes semis de Cyclamen une plante qui attirait mon attention par l'extrême beauté de son feuillage dentelé et marbré. En examinant la plante, je vis qu'elle portait une grande quantité de boutons; ceux-ci étaient de forme plus arrondie et plus courte que ne le sont généralement ceux des Cyclamen persicum. La plante fut mise aux; quand elle commença à fleurir, elle m'étonna par la forme bizarre de ses fleurs. Ces diverses circonstances m'engagèrent à en récolter les graines.

FIG. 112.—FLOWER OF SPREADING CYCLAMEN. See p. 347, *ante*. (Reduced one-half.)

FIG. 113.—FLOWER OF BUTTERFLY CYCLAMEN.

afterwards to have been lost sight of.* It has also occurred in a red-flowered form in France,† in which case it was also perpetuated by seed.

I have not succeeded in discovering any similar structure in any primulaceous structure occurring in a wild state. Dr. Masters, however, informs me that it has been observed in cultivated forms of *Primula sinensis*. The tendency thus seems to be latent in the order, though why it should be so I am unable to explain.

Some theoretical interest appears to me to attach to the rapid development of so striking an ornament of a corolla segment. Such appendages are frequent enough in Orchids, and are regarded as adaptations to cross-fertilisation by insects. Their gradual evolution might be thought to require a long period of time, but in the present case we have definite evidence that such a structure may be developed by selection with great rapidity.

Conclusion.—1. The facts which I have stated appear to me to establish the result that when once specific stability† has been broken down in a plant, morphological changes of great variety and magnitude can be brought about in a comparatively short space of time. This appears to me to have a very important bearing on the rate of evolution. Mr. Darwin

FIG. 114.—CRESTED CYCLAMEN.

"L'année suivante j'obtins quelques jeunes plantes. Au moment de leur floraison, elles purent être comparées à la plante mère.

"Les plus parfaites de ces plantes furent choisies pour servir de porte-graine, et leurs fleurs furent fécondées entre elles. L'année suivante je fus assez heureux pour constater un nouveau progrès; mes gains surpassaient leurs parents que j'avais conservés. On pouvait apercevoir, dans ces semis aux caractères persistants, le point de départ d'une race nouvelle.

"Je continuai dans cette voie; au bout de quatre ans, j'étais en possession de quelques sujets fort remarquables. Les pétales des fleurs étaient aujets et plus longues; ils se redressaient comme les ailes d'un papillon qui s'appri-t à prendre son vol.

"La race se caractérisa chaque année davantage. Encouragé par le résultat déjà obtenu, je m'occupai à rechercher la diversité des coloris. Après quatre années je ne possédais dans mes semis que des plantes à fleurs rouges; j'avais en triant les sujets pour la reproduction toujours écarté les fleurs les moins brillantes. Il s'agissait maintenant d'obtenir des fleurs à couleurs pâles. Des efforts nouveaux furent fait dans cette voie; je vis au bout de deux ans après apparaitre la première fleur aux pétales blancs et à onglet rouge; dès lors les croisements se multiplièrent au point qu'après la neuvième année la perfection des formes et des coloris est telle qu'on tous ceux qui voient mes Cyclamen Papilio sont unanimes à reconnaître leur mérite et leur perfection des fleurs."

branch. This was, however, considered sufficiently curious to follow up, and we seeded it with its own pollen.

"The young plants from this showed a decided improvement, the rib in some cases showing a marked tendency to branch. The best varieties (ten in number) were again fertilised with their own pollen, and the plants now being exhibited by us have resulted, although, needless to say, they are among the finest obtained up to the present, though all show a further improvement, every flower having a well-branched feather on the petals.

"We have this year found some colour in one plant, and we believe we shall have no trouble in obtaining crested flowers in a variety of colour."

The corolla segments of Cyclamen have no mid-rib. The appearance of such a structure is a reversion to the original leaf-type. The development of a crest from a mid-rib carries reversion very far back indeed. The branching of a leaf-structure in the plane in which it is expanded is common enough; branching in a plane at right angles to this is rare. Leafy outgrowths frequently occur from the mid-rib in the Cabbage.* In this case the structure of the leaf approximates to that of a stem, of which, indeed, the leaf may be regarded as a modification.

An interesting fact with regard to this singular variation is that it has appeared more than once, and independently. It first occurred in 1885, but seems

quotes Lord Kelvin as insisting "that the world at a very early period was subjected to more rapid and violent changes in its physical condition than those now occurring;" and he adds, "Such changes would have tended to induce changes at a corresponding rate in the organisms which then existed."‡ That changes may be effected with considerable rapidity cannot, I think, be denied.

2. It is further, I think, abundantly proved in the present case that, though sudden variations do occur, they are, as far as we know, slight so long as self-fertilisation is adhered to. The striking results obtained by cultivators have been due to the patient accumulation by selection of gradual but continuous variation in any desired direction.

3. The size which any variable organ can reach does not appear to be governed by any principle of correlation. Large flowers are not necessarily accompanied by large leaves. Under natural conditions size is controlled by mechanical limitations and by the principal of economy. Nature cannot afford to indulge in anything unnecessary for the purpose in view.¶

4. The general tendency of a plant varying freely under artificial conditions seems to be atavistic, i.e.,

* *Gardeners' Chronicle*, 1885, p. 539.

* Masters' *Teratology*, p. 455.

to shed adaptive modifications which have ceased to be useful, and either to revert to a more generalised type or to reproduce "characters which are already present in other members of the same group."* This conclusion must, however, be accepted with caution, for we must remember that in a case like the present we are only acquainted with variations which have been preserved with a particular end in view.

5. The case of "cresting" shows that the plant still possesses the power to strike out a new line, and to develop characters which would even be regarded as having specific value, as in the total change which has been effected in the form of the leaf in *Primula sinensis*. If such a race developed any degree of sterility with other races, it would have satisfied Huxley's criterion for the artificial production of a new species.

TREES AND SHRUBS.

RIBES SPECIOSUM (R. FUCHSIODES).

Of the two sections of the genus *Ribes*—the Gooseberries and the Currants—the latter contains much the more important species when regarded as ornamental shrubs. Amongst the former, *R. speciosum* is by far the most attractive. It is frequently treated as a wall-plant, and does, no doubt, flower with greatest freedom in that position, but that it is perfectly hardy, and blossoms profusely when planted in ordinarily exposed positions, is shown by a specimen flowering in the arboretum at Kew. The flowers appear (usually three together) in short racemes from each joint of last year's wood, and hang in a long row from the underside of the branches. The calyx is the most prominent feature of the flower, being half an inch long, tubular, and almost entirely covering the petals. It is of a deep scarlet colour, and is covered with short hairs at the base. Standing out beyond the calyx, and twice or thrice its length, are the stamens, which have the prevailing red of the flower, but of a pinkish tinge. The leaves are like those of the common Gooseberry, but smaller, and three spines guard each joint of the wood. Its recommendations as an ornamental shrub consist in the bright and unusual colour of its flowers, and in the Fuchsia-like grace with which they hang from the shoots. It is a native of California, and was first introduced in 1828, but it had been discovered by Archibald Menzies some thirty years previously. [Our experience is, that this species needs protection in the winter in the Midlands and the North. Ed.]

CYTISUS ALBUS.

So few among the *Cytisus* and *Genistas* have other than yellow flowers, that the white ones of this "Portugal Broom" give it a special value. But besides the colour of its flowers, their great abundance and the striking habit of the shrub entitle it to a place in the first rank among hardy plants. It produces a mass of slender, wiry, green twigs, whose abundance give it the character of an evergreen. The leaves, indeed, are never much in evidence except in seedling plants, when they are trifoliate; in older specimens they are usually quite small, simple, and linear. The flowers are milk-white, and appear two or three together in a fascicle at each node. The habit of this shrub is somewhat erect when young, and with age it becomes bare at the base, the crowded mass of young branches then forming a heavy, but not ungraceful crown. In early May this is transformed into one single mass of white, and is most beautiful and striking. This *Cytisus* grows 6, 10, or even more feet high, and is useful for planting towards the back of a shrubbery where the smaller things in front hide its naked base. When planted in more exposed places, it should be frequently stopped when young, so as to get plenty of branches near the ground.

RHODOTHAMNUS CHAMÆCISTUS.

To most persons this small growing shrub is better known, perhaps, by repute than by experience

cultivating it. It is one of a sufficiently numerous class whose cultivation it is much easier to tell other people about than to successfully accomplish oneself. It was introduced considerably over a hundred years ago, Messrs. Loddiges, of Hackney, having had seeds sent to them from the mountains of Carniola in 1786. Yet during all these years it has been rare, and seems likely to remain so, for it is one of the most difficult of Ericaceous plants to thoroughly establish, even in gardens where *Rhododendrons* and similar shrubs thrive perfectly well. There are, however, a few places where it succeeds (with Messrs. Backhouse, of York, for instance), and it is then one of the most charming of the dwarf Ericaceae. It is a dwarf procumbent shrub, whose branches are thickly set with small ovate, hairy leaves. The flowers are borne in April and May in clusters, at the ends of the branches. From two to four are in each cluster, the flat corolla being a little more than 1 inch across, and of a pale pink tint. A plant has flowered recently in the Kew rockery, where it was planted some years ago in a niche between two stones, and it is now become established. W. J. E.

NARCISSUS POETICUS.

MODERN horticulture has come to look upon only well-marked species of a valuable genus of cultivated plants that is at once beautiful in itself and fertile in both seed and pollen, as not only an end but a means. Or rather, we should say, that such a plant has a three-fold aspect, its own beauty and worth as it exists at present, its possibilities of evolution *per se* to enhanced perfection of size, form, and other desirable attributes, and its value as a factor in the production of new forms when interbred with other species. *Narcissus poeticus* is of high merit in all these ways, though, strangely enough, the second, namely, its improvement within its own limits, has been altogether neglected, so far as I know, save for some attempts of my own. It is remarkable that this flower appears both first and last of the cut Narcissus which fill the markets for quite five of the winter and spring months. Enormous quantities of the early Pheasant-eye *Narcissus p. ornatus*, are forced into bloom in January and February, and for the market gardener there has probably been found more money in this than in any other "Daffodil." In the middle of May the double poeticus, a very attractive Gardenia-like flower, closes the season of the *Narcissus*. These two, with the old-fashioned *recurvus*, known exclusively as the Pheasant-eye *Narcissus* before the advent of *ornatus*, are the popular varieties, but several others are well distinguished, as might be expected from the wide geographical distribution of the wild plant. Roughly speaking, it extends in latitude from Switzerland to central Greece, and in longitude from the Western Pyrenees to Transylvania, whence Mr. Wolley Dod informs me he has received collected bulbs, and possibly somewhat further east, as it has been asserted that the cultivated variety known as *grandiflorus* was brought from the Crimea. In days when plant-geography was less exactly studied than now, *N. poeticus* was sometimes admitted into the British Flora, but the form in which it occurs, apparently wild, in a few English localities is that of *patellaris*, the type abundant at Verey, Montreux, and other Swiss places of summer resort, whence it was, no doubt, brought to England by tourists, and subsequently naturalised by escapes from gardens. This flower has broad, firm perianth divisions, and the corona very flat, whence its varietal name, with a clearing of white inside the narrow red rim; it flowers very late, and seems to be the single form of the common double poeticus. Generally speaking, the species diminishes in beauty, according to the florists' standpoint, as it passes from west to east. In the high Pyrenees, where, in July, it whitens the mountain pastures, especially in the Luchon district, it is very variable, but many fine well-formed flowers may be selected, some with the corona wholly red and not merely edged with colour. Mr. James Allen, of Shepton Mallet, several years ago collected and kindly gave me bulbs of some of the best of these; they were late-blooming, and unfortu-

nately did not prove robust in cultivation. The precise origin of *ornatus* has not been ascertained, but the wild flowers which resemble it most closely in form and earliness have come to me from Provence and North Italy. On the North Italian mountains poeticus takes a very dwarf alpine habit, but as regards shape of flower, I have picked out exact counterparts of *ornatus* on the high pastures above the Lake of Como in the month of April. It is curious that stray bulbs of this dwarf plant were brought to England from the vicinity of Lake Maggiore in Dean Herber's time, as a rarity, and named *N. p. verbanensis*. It is really the prevailing *N. Italian* type, and extremely abundant. *Ornatus* was known in the Paris markets long before its introduction into England. This early, white, fragrant flower, absolutely vigorous, of rapid increase, and blooming from the smallest bulb, is one of the very best additions of this generation to our spring gardens. The variety *poeticum* may also be of Italian origin; it has the entire corona bright red, but the perianth is of flimsy, semi-transparent substance. It flowers in succession to *ornatus*, but is less robust in most soils. Another Italian variety, *precox*, flowers very early, but is otherwise of inferior merit. Further east, *N. poeticus* assumes a narrow-petalled form. Mr. Baker tells me that the only Greek specimen in the Kew Herbarium, from the Pindus range, has divisions a quarter of an inch in width; and Mr. Wolley Dod's plants from Transylvania bore the same type of flower. It is not, however, safe to conclude that the garden varieties named *angustifolius* and *stellaris* are necessarily of eastern origin, for wherever the wild poeticus abounds, narrow as well as broad-petalled flowers occur; and among my own seedlings from the finest circular types, a percentage of flowers appears with almost linear segments.

There is a variety in cultivation to which the name poeticus versus of Linnaeus has been given, quite arbitrarily, I think, small, with round, well-shaped flowers; this is said to be of Greek origin, but I know not on what authority. *V. grandiflorus* has the appearance of a form from Eastern Europe; it is a somewhat ngainly flower, with narrow, spreading segments, and is of little value for the garden. Of the common *recurvus*, which must, I think, be referred to the wild lowland type of poeticus prevailing in South-western France, there seem to be some superior and inferior varieties in cultivation, some having flatter, broader divisions than others. A distinguishing character is its lax foliage, reflexed for half its length, whence possibly its varietal name, though this has been thought to refer to its reflexed perianth. This old flower is still of considerable market value when highly cultivated. Some other varieties of poeticus with distinctive names are not of cultural importance. The vain attempt has been made to identify the many sorts enumerated by Parkinson under elaborate Latin names, which are merely descriptive of the minute differences in plants which he received from foreign collectors, and probably often from the same mountain-side.

N. poeticus has had a very large share in the creation of our modern garden *Narcissi*, since Dean Herber, half a century ago, verified by experiment his guess that *N. inconparabilis* was a hybrid between it and the Trumpet Daffodil. To it the classes known as *N. incomparabilis*, *Barri*, *Nelsoni*, *Leedsii*, *Burbridgei*, owe their robustness, their extended blooming season, and the orange or red of their crowns, which is in all cases the solution or suffusion of the concentrated colour in the purple or deep red thread round the poeticus crown. A noteworthy proof of the power of poeticus to give vigour to its hybrids is found in the group *N. Leedsii*, many of its varieties being of indomitable constitution, though their other parent, the white Trumpet Daffodil, is the most fastidious of its kind.

It is surprising, if we consider the many fine qualities of this plant, that while so much pains was bestowed upon the production of its hybrids, nothing was done towards the improvement of the poeticus pure and simple. It is certain that, by careful seed selection and intercrossing of varieties which supplement one another's deficiencies in these points, it

* See Darwin, *Orig.*, 6th ed., p. 127.

may be at least as largely advanced as the Trumpet Daffodil has been in size and in attractiveness of form and colour. And such improved poeticus would in turn give us improved hybrids.

The cultivation of the poeticus is easier than that of most other Narcissi, but two memoranda should be made—first, that it is more capable than the rest of assimilating nitrogen—or, in plain words, that it

AMELANCHIER CANADENSIS VAR. OBLONGIFOLIA.

THE species and varieties of Amelanchier are by no means easy to distinguish one from another. To aid in the task we now give an illustration (fig. 115) of a plant which was in flower recently at Kew, and a description of which by Mr. Beau was given in a recent issue (p. 265).

FIG. 115.—AMELANCHIER CANADENSIS VAR. OBLONGIFOLIA.

like farm-yard manure; and, secondly, that it is the earliest to make fresh root-growth, and therefore should be the first to be attended to in the matter of lifting and replanting. On poor, dry soils, the double poeticus is apt to bear blind spathes; but where it is amply supplied with manure and water, it yields flowers as fine as white Camellias. G. H. Engleheart

details of experiments with various manures on different plots of Sugar-cane. The plots were duplicated, but the variations in the yield of some of these duplicated plots is greater than the variation caused by the application of the manure. This plainly brings out the fact that the variations in yield due to soil condition are more important than those produced by the action of manures.

HONG KONG.

The typhoon which swept over the Colony on July 29 was the severest experienced here since the disastrous one of 1874. The gardens suffered very severely by the loss and injury of trees and shrubs, which, together with the losses in 1894 from successive typhoons of that year, left traces which will take many years to recover from. The plant-houses and other structures received but a small amount of damage owing to timely and efficient precautions having been taken to secure movable parts in such a manner as ensured their safety. Portions which were carried away were renewed in a more substantial manner. The glass-houses came out of the storm unscathed, with the exception of a few pieces of glass broken by material falling on them.

Many trees and shrubs were completely stripped of their foliage, but new growths of branches and leaves were quickly made, and in some instances trees which flower usually only once a year produced a second crop of flowers on the new shoot. The rainfall for the year as 77.6 inches.

SINGAPORE.

The most interesting item in the *Report of the Botanic Garden* for home readers is the account of Mr. Curtis' botanical tour in the Malay States, from which we extract the following paragraphs:—

"On the second day we tacked about without making much progress until 5 P.M., when we landed on Pulau Panjang to do some cooking, and while this was being done I collected a few plants. *Cirrhopetalum Medusa* appeared to be abundant on rocks in this island. At 6.30 P.M. we started again with a fresh breeze, standing straight across for the picturesque islands near the entrance to the Kasum River, under shelter of one of which, Pulau Prabat, we anchored until 5 A.M., when we got under way again. At 7 A.M. we landed on a small island to cook and collect plants; the most interesting kinds found here being two species of *Begonia* and two of *Pogonia*, the native name of one of the latter being 'elephant ear.' From this place we proceeded slowly against wind and tide to Kasum, which was reached between 3 and 4 P.M., so that I had actually been about forty-nine hours from Tongkah.

"The scenery among the islands before entering the Kasum River is magnificent, scores of islands of the most fantastic forms rising abruptly from these to a height of several hundred feet. Similar scenery may be seen in Lingkau, but on a much reduced scale. On arrival in Kasum I sent my letters of introduction to the Governor, with a request for an empty house if possible. In a short time I received a message that the Governor was suffering from fever, and would not be able to see me for two or three days, but that a house was being prepared for me. This was the one decent looking house in the village, originally intended, I was told, for a post-office; but as soon as the men commenced cleaning it out, it was found to be unsafe, so I had to go into a Chinese attap-house in the main street. For a place of its size, and it is a village of about a hundred houses, and perhaps 700 to 800 inhabitants, Kasum is the most miserable looking place I ever set eyes on. The main street is overgrown with weeds, and in places knee-deep in mud. On either side are tall Bamboos leaning at all angles with the remnants of banners dangling in the breeze, the remains of the decorations of some religious festival long past. The houses are of plauk and attaps, with very sharply-pitched roof, and a sort of covered 5-foot way in front; but it is only in places that one can cross from one side of the street to the other without sticking in the mud. A few days' residence in the place has a

COLONIAL NOTES.

ANTIGUA.

THE report of the results obtained on the Experimental Farm in this island by Mr. Watts, Government Chemist, and Mr. Shepherd, Superintendent of Skerrett's School, has reached us. It contains

most depressing effect. The morning after arrival, I collected Orchids, &c., along a road that was commenced three or four years ago, and cut for a distance of about 4 miles to a place called Wattam, where there is a Hinduist temple in a cave in the limestone rock with numerous figures rapidly going to decay. One of the figures in a reclining position is about 45 feet long. I spent some time in botanising on this hill, and collected several interesting plants. One of the priests showed me a plant of *Dendrobium Farmeri* fastened on a block of wood which he assured me was very rare, and, so far as my experience goes, it is so, for I only collected two plants of it during the time I was there.

"On the second day, the Governor sent me a man who spoke Malay to accompany me anywhere I wished to go, and to assist me generally. Two days I went down the river to the limestone hills, and on another day walked across to Pongah and slept there, returning by another route the following day. The distance I estimate to be about 10 or 12 miles. Pongah is not so nice a place as it was in the old Rajap's time; things are fast going to decay. It is interesting to note that several natives have a few Orchids growing around their houses, and one has quite an interesting little collection; and this, they told me, was the result of my previous visit. *Dendrobium Farmeri* is evidently the kind they prize most, which shows good taste on their part, but it is scarce, and they set a value on them that prevented me from buying. This is abundant in Mergui, and Pongah is apparently about its southern limit. One very interesting *Dendrobium* I saw in a garden which I was most anxious to get, but the owner would not part with it; he, however, gave some flowers to dry which will, I hope, be sufficient for determination, but I have little doubt it is an undescribed species. On the limestone islands I collected a great number of interesting, and some, I believe, perfectly new plants, among the latter being a Ginger, Balsam, and Arum.

"Many plants we observed that it was quite impossible to get at, but, on the whole, I made a very satisfactory collection. The Ginger, which I believe to be new, and of which I only saw a single flower, although it had been flowering freely not long previously, grows in the cracks of the hardest rocks, where it is impossible to get at the roots without blasting them out. I saw hundreds, but only succeeded in getting about half-a-dozen, three of which I have sent to Kew. Of the Balsam, I dried a good series of specimens, and collected a nice lot of seeds, and of the Arum tubers.

"In one place, I saw enormous clumps of *Cyrtopodium*, but quite out of reach, and also a small growing *Aerides* (*Aerides* affinis). For miles round Kasum the virgin forests have all been destroyed by the paddy-planters, and the present vegetation is composed largely of Bamboos, of which there are four species so abundant that they may be said to be the prevailing feature of the vegetation on all the low hills.

"A lazier lot of men it would be difficult to find, and the only thing that really livens them up is a cock-fight, then the village turns up like one man!"

THE WEEK'S WORK.

PLANTS UNDER GLASS.

By G. H. MACVOCK, Gardener, Luton Hoop Park, Luton.

Colosias and *Cockscombs*.—Repot these as soon as necessary, and keep them in a position close to the glass in a moderate temperature, and do not permit them to want for water. It is good practice to plunge the pots to the rims in Cocoa-nut fibre if the weather be hot. Keep a sharp look-out for thrips and red-spider.

Poinsettias.—Preparations should now be made for those intended to be planted out in frames such as those from which early Potatoes have been dug. Take out some of the old soil, and replace with that mixture of loam, leaf-mould, and sand. Plants that were cut hard back after flowering will require more space than the spring-struck cuttings. These latter, however, I prefer to keep in pots all the season. Put out the old plants at 2 feet apart, and shade a little from strong sun until the fresh roots have obtained a hold of the new material. It is of the utmost importance that every plant should be clean and free from insects before they are planted out. Sprinkle the plants frequently. Move on the spring-struck

cuttings into 5-inch pots, and keep in a temperature of 60° by night and 70° by day, pinching the points to induce a bushy growth. They should be moved on again into 7-inch pots as soon as these are well filled with roots. They may then be placed in a sunny position in cold frames, where they can be kept close to the glass. The lights may be removed altogether about the middle of August.

General Work.—Shake out and pot on old stock-plants of *Euphorbia Jamburana* and *E. pulcherrima* (*Loisnetia*) from which cuttings have been taken, and place them in a gentle hot-bed for a few weeks; but when it is seen that young roots have been made, gradually harden-off the plants, and treat them similarly to spring-struck cuttings. Afford shade to *Calceolarias* in bloom, water the plants with care, and remove all decaying blooms. A little air may be admitted to the structure by night and day to prevent damping, and the watering should be done early in the morning. Remove into larger pots all winter-blooming plants as soon as they are ready, such as *Sarcocolla*, *Crotoneas*, *Agathae coelestis*, &c. If the cuttings were struck five or six in each pot, they should be divided before the roots become entangled. Examine young plants of *Cyclamen* for thrips, and if any are observed, fumigate the plants at once; inattention in this respect may lead to blindness. A lens is requisite to detect white thrips that may be secreted in the crowns. *Salvias* if struck now will flower in small pots, and the old plants may be put out in the open ground to grow into extra-sized specimens. If they be planted in a shallow trench with less labour in watering will be requisite. Afford copious supplies of water to *Canas* in pots, and give them weak manure-water once each week.

THE KITCHEN GARDEN.

By W. POPE, Gardener, Highclere Castle, Newbury.

Asparagus.—Apply a good dressing of common salt to beds now producing heads. If this be applied in dry weather it will help to keep the beds free from weeds without in the least injuring the young tops of *Asparagus*, and when carried to the produce it will become a very good manure. If the produce is weak from the beds being overtaxed in previous years, cutting should be discontinued early. Occasional dressings of guano may be applied during showery weather.

Mushrooms.—Continue to make up Mushroom-beds in the open as fresh manure is available. A good proportion of straw-litter should be left with the droppings for these out-of-door beds, but care must be taken that the material be not too dry when used, this being a frequent cause of failure. Should more moisture be desirable, sprinkle well the manure with water, and throw it into a heap, turning it daily for a few days before making up the bed. Eat or tread this firmly together, and insert the spade when the temperature is about 75°. Afterwards cover with 2 inches of good garden soil, which should be beaten firmly together with the spade, and covered with clean straw or mats.

Peas.—A good breadth of these may be sown now to come into use in August. At this time of the year it is sometimes advisable to sow in trenches, which will help them to withstand drought when coming into bearing. The manure used should be rich, and thoroughly decomposed. Well work this into the bottom of the trench, formed by taking out 1 foot or 15 inches of the surface soil. Return as much soil to the trench as needed, and tread firmly before sowing the seed. Should there be any likelihood of a break in the supply earlier, sow a row or two of an early variety at the same time as the foregoing, which will tend to lengthen the season of bearing. Earth and stake advancing crops before they are tall enough to be injured by high winds.

Hoing and Cleaning Vegetable Crops.—Use the Dutch hoe frequently amongst growing crops for the double purpose of keeping the ground clean, and by a loose surface lessening the amount of evaporation during hot, dry weather. Should any weeds have arrived at the flowering stage, let them be pulled up, and taken off the ground before hoing begins. In the case of many weeds, such as Groundsel, *Charlock*, &c., if the flowers are allowed to open, many seeds will mature after the plants are cut off; therefore, clear them away at once. By a free use of the hoe whilst weeds are young, much labour will be saved, and the soil kept in the best possible condition. Water any newly-planted vegetables that may be suffering from drought, those that may have been turned out of pots being especially liable if neglected in this respect, as the roots require time to penetrate the

surrounding soil. Newly-planted *Celery* requires frequent supplies, and freshly-planted *Tomatoes* at the foot of walls or fences. Remove the lower heads from *Rhubarb* and *Sorrel*, as these weaken the roots to no purpose. Old plantations of these will be greatly benefited by watering with liquid-manure, more especially the former. Discontinue pulling *Rhubarb* as soon as possible, or at least from a number of the roots that will be required to furnish produce early next year.

FRUITS UNDER GLASS.

By F. HARRIS, Gardener, Easton Castle, Lebury.

Succession Peaches.—The trees which follow those in the early house will now have passed through the stoving period, and if they are not young trees, and are carrying good crops of fruit, occasional applications of liquid-manure, or failing that some artificial manure, will greatly improve the size and quality of the fruits. Ordinary fish-manure I find to be very beneficial to Peaches, and if the foliage is lacking in colour, one or two moderate applications well washed in with tepid water will speedily induce a healthy dark green tint. I first tried it for a few years past on two very old trees in pots that had been condemned to the rubbish heap but after two seasons the trees so improved that they are now carrying good crops of fruit, and looking as healthy as any of our young trees. If the fruit has not been exposed to the light and sun, it should be done at once, and all shoots not required for next year, and that are not bearing fruit, should be removed, thereby giving next year's bearing wood a better chance to ripen well. Use the syringe frequently, especially in the afternoon at closing time, to prevent red-spider getting a footing. The house may now be closed a little later as the sun is likely to be powerful, and trees are impatient of a high temperature. If the temperature shows signs of rising above 85°, a little top-air should be left on for half an hour. I firmly believe that a high temperature is sometimes the cause of Peaches and Nectarines casting their fruits.

Late Houses.—Trees that have been retarded as much as possible will have set their fruits ere this, and usually in these houses there is a very heavy set; therefore no time should be lost before thinning is commenced, otherwise a needless strain will be laid upon the trees. Disbud the shoots gradually, and at the same time rub off all the small and deformed fruit, leaving two or three which are in the best position on each shoot. In a few days afterwards, when it can be seen for certain which fruits are taking the lead, remove the others, taking care that the crop is as evenly distributed as far as possible over the tree. If it is wished to keep both trees as much as possible, ventilate the house all night, unless there is likely to be frost or very cold winds. Heel in the permanent shoots as soon as possible, taking the points out of others not required. If there are any signs of aphid, fumigate lightly on successive evenings after the sun has gone down, well syringing the trees early next morning before the sun gets powerful.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorking.

Phalænopsis.—Few Orchids equal these in graceful beauty when in bloom, the long arching spikes of such well-known species as *Phalænopsis*, *P. amabilis*, *P. grandiflora*, *P. Aphrodite*, *P. castanea*, *P. Stuartiana*, *P. intermedia*, *P. Portei*, *P. Schottiana*, and *P. leucorrhoda*, produce large spikes of flowers that last in perfection for many successive weeks. Coming from some of the hottest regions of the East, these plants require the temperature of the East Indian house, or the warm humid atmosphere of the plant-stove. They appear to thrive best when suspended close to the roof-glass on the north or shady side of the house, and where they obtain a fair amount of light, but not actual sunshine. Such sun-beamed varieties as *Leucostemmanium*, *P. Marie*, *P. speciosa*, *P. tetraspis*, *P. violacea*, *P. cornu-tervii*, *P. sumatrana*, *P. rosea*, *P. Michelozii*, *P. Manni*, &c., are very susceptible to injury from strong light at any time, stand them therefore low down upon the stage where they may be overshadowed by taller-growing species. The semi-terrestrial *P. Esmeralda* grows freely when suspended to the roof, and the same remarks apply to the deciduous *P. Lowii*. At this season, the majority of these plants have passed their flowering period, and have commenced to make fresh leaves and roots, therefore if any of the plants require to be top-dressed or repotted, this may be done. It is not good practice to rebasket the plants every year, as they dislike to have their roots detached

from substances they may be clinging to, but they will remain healthy in the same baskets for several years, providing the Teak-wood does not decay. Those plants that are in a healthy condition, well rooted, and have sufficient room for further development, should be relieved as much as possible of the old moss, which should be replaced with new material. Plants that require such attention should be placed at one end of the house, and allowed to become somewhat dry. In the case of those that require more space, great care is necessary in removing them from the old baskets, as the young roots are very susceptible to injury. Carefully pick out the sphagnum-moss and drainage material, then soak the basket, &c., in tepid water for a minute or so; the roots may then be easily detached from the wood with a sharp, thin-bladed pen-knife. It is important that new teak-baskets be used, as the young roots attach themselves more readily and firmer to new wood than to old. In transplanting the plant into the new basket, carefully arrange the roots around the teak rods, and keep the collar of the plant a trifle above the top rod. These proceed to fill the basket to three-fourths of its depth with clean broken crocks. The remaining space around the base of the plant should be filled with living sphagnum-moss, mixing some small crocks with it to assist drainage. This is very important, because if the roots are buried in a solid heap of moss, which may become saturated, they will quickly decay. Weakly plants, having few or no roots, should be placed in small Orchid-pans, and suspended from the roof. When they are in better condition, they may be transferred to baskets again. After top-dressing or re-basking, very little water is necessary. On no account should the plants be saturated by the usual dipping, it being safer to sprinkle the moss on the surface and around the sides of the baskets with tepid rain-water, applied through a fine rose watering-can. Afford no more water than is necessary to keep the surface-sphagnum alive, and prevent water getting into the centre of the growths. In houses where the atmosphere is nearly always at saturation point, insect pests rarely attack Phloxopsis; but where the house is naturally dry, thrips multiply with great rapidity, and quickly disfigure the handsome foliage. Periodical fumigation with the XL All Vapouriser is an efficacious remedy; and good results may be obtained by washing the leaves occasionally with a soft sponge and clean rain-water. For a month or two look carefully over the plants at night for slugs.

THE FLOWER GARDEN.

By CHARLES HERRIS, Gardener, Dromore, Maidenhead.

Bedding Arrangements.—In warm districts, the bedding-out of the tender plants may now be commenced. If the flower-beds contain no spring-flowering plants, hardy edgings may be put out, and the ground-work of any carpet or other bedding design it is intended to use. A more pleasing style than carpet-bedding, however, is now prevalent, and plants of somewhat hardier and less formal characteristics are used. As these notes are written the weather is anything but genial, frosts occur almost each night, and by day a cold northerly wind and little sunshine is present. No tender plants should, in such circumstances, be exposed until a change takes place. Even in the case of Pelargoniums that have been hardened-off for some time in cold pits and frames, it will not be advisable to plant in such inclement weather, unless some temporary shelter can be provided on frosty nights. Where Sedums, Echeverias, and such-like, are used for edgings to beds on grass, the Sedums may be pulled into pieces, selected and re-planted after the edges have been prepared by adding a little new soil. The variegated grass—*Daelytia glomerata variegata*—makes a capital edging-plant, and is perfectly hardy. Old clumps, if lifted now, and pulled into small pieces, will make nice plants in a few weeks, and form a suitable edging to beds of scarlet or pink Pelargoniums. Summer-flowering Violas, when used in mixture with Pelargoniums, or as a ground-work for a mixed bed, thrive best when planted early; but if they are not already planted let this be done at once. The dark purple Viola, Archie Grant, associated with the variegated-leaved Lady Plymouth Pelargonium, is an effective arrangement; and a white-flowering Viola, as Mrs. Gray, may be used in conjunction with the White Brighton Geranium or Vesuvium scarlet-flowered Pelargonium. Where a taller and mixed bedding arrangement is possible, Fuchsias are admirable subjects; and if plants have been grown on as advised in early Calendars, they will now be strong plants, 4 to 5 feet in height, and well adapted for this purpose. Fuchsias such as these, dotted over

large beds, with a carpeting of Violas, and interspersed with tuberous Begonias, 18 inches to 2 feet high, together with a suitable edging, make a pleasing arrangement. As examples, I may give the following—*Fuchsia Madame Cornillon*, and *crimson and red-flowered tuberous Begonias*, on a ground-work of *Viola Bluebell*, and edged with the golden-leaved *Lysimachia Nummularia*; *Fuchsias*, Mrs. Marshall, 4 to 5 feet high, bed carpeted with *Viola Bluebell*; *Begonia semperflorens*, Duchess of York, 1½ foot, edged with a good band of the trailing *Fuchsia Mator*; dark *Heliotrope Florence Nightingale*, 4 to 5 feet, with a scattered undergrowth of *Nicotiana glauca* and scarlet-flowered *Pelargoniums* to half the height (about 2 feet); ground-work, *Alternanthera versicolor*, with an edging of *Mesembryanthemum cordifolium variegatum*.

Herbaceous Borders.—Varieties of *Paeonia montana* in sheltered positions are now in flower, but the severe frosts, after they were well into bud, destroyed many shoots, the flower-stems completely shrivelling up to a less extent. Later-flowering varieties might be relieved of some of the small flower-buds if large blooms are desired; if not, these back buds open later, and so form a slight succession, although the flowers are smaller. A good soaking of liquid-manure is of much assistance to established clumps of these *Paeonies*. *Delphiniums* in variety should be staked and tied before they become long enough to fall over, and so grow out of shape; when this occurs, they cannot be easily tied erect again. Other subjects requiring short stakes and ties are *Oriental Poppies*, *Asphodelus albus*, *Sweet Rocket*, &c. During the present dry weather, keep all borders well hoed over. The past week, although cold, has been very favourable for hoeing and cleaning.

THE HARDY FRUIT GARDEN.

By H. W. WARR, Rayleigh, Essex.

Training the Young Growth of Wall-Trees.—The training of young growths of wall-trees requires almost daily attention during the present and four following months. The terminal growths of leading shoots should be secured in position on the wall by means of nails and wire, or, if the wall is wired, by means of one or lateral growths between each pair of branches with Birch or Hazel twigs. In the case of walls provided with a series of wires, fixed either horizontally or vertically at distances of 6 inches from each other, small bands of raffia or bast are employed for the same purpose. Twist the matting once round the wire to prevent its shifting from the desired position before tying the individual growths thereto, being careful to leave ample room in the ligature for the free expansion of the shoots. Peach and Morello Cherry trees, owing to the multitude of young growths, require prompt and frequent attention during the period of growth, the treatment being identical in each case. A sufficient number of the current year's growths being laid in for producing fruit next year, all surplus shoots, together with fore-right growths, being kept persistently pinched (and in some cases rubbed off) to within one joint of their origin. Very strong growths should be cut back to the lowest lateral or removed in order to direct the flow of sap into the weaker ones. Apricot, Plum, and Pear trees require the same treatment as regards the training of young growths at regular intervals over the available wall-space, and the pinching of the same in the manner and for the purpose described above.

Insect Attacks.—Care should be exercised to keep all kinds of fruit trees free from the attacks of aphid and red-spider, and of mite; and where these undesirable visitors have effected a lodgment on the young growths, prompt and effective remedial measures must be taken to dislodge them. The most difficult of dislodgement is the black-fly, which almost confines its vigorous and persistent attacks to the young growths of Cherry-trees. I have sometimes found it necessary to dip growths thus attacked in saucers containing a solution of the "XL All Insecticide" (in the proportion of one part to thirty of water), or tobacco juice and water at the rate of water of the former to four gallons of the latter. The XL All Insecticide applied as above to Peach-trees affected with either green-fly or red-spider will have the desired effect. However, the aim of the cultivator should be to keep his trees—especially wall-trees—clean and healthy by a vigorous, timely, and well-directed use being made of clean water applied to the trees by the hand garden-engine or syringe, in addition to keeping the soil about the

roots uniformly moist, but should this fail in securing the desired result, recourse must then be had to insecticides.

THE APIARY.

By EXPERT.

Feeding in the Open.—When the apiary has grown to a size that the stocks may be counted by the hundred, the bee-keeper has to get through his work speedily, and outside spring feeding works admirably, especially where time is a consideration. With the food-dish placed in a suitable spot, it is only necessary to pour in the supply on every fine day, when the bees will be found eagerly waiting for it. This occupies but a few minutes daily, and there is no danger of damage, which sometimes occurs from uncovering the brood nest to its detriment; nor is there any fear of mischief happening, as it may with the ordinary spring stimulating feeder of the bottle and stage pattern, such as allows the syrup to run down amongst the combs and partly drowns the bees. Any person, if once shown the right way, can give a supply of food outside; and even where but few hives are kept (provided they are isolated from other stocks in the district) the plan of open-air feeding has much to recommend it. Those who have not given this system a trial, and who may desire to do so, should observe the following rules, viz.: (1) Place the syrup dish in some sheltered warm spot, 30 or 40 yards away from any of the hives, and provide in it for a float some spent Tea leaves or cut straw. (2) Put into an earthenware crock or other dish some granulated sugar; pour over it some boiling water, stirring till all is melted. This liquid must be much thinner than the ordinary syrup used for autumn-feeding; it should be similar to doubly-sweetened tea. (3) About 9 a.m. on any fine day pour into the food dish a supply of the syrup—1 lb. of sugar daily, to say, eight or ten stocks, will be enough for stimulating purposes. (4) On dull, cloudy, or wet days the supply should be stopped; but even then, if the weather is not of a nature to chill the bees, some temporary cover may be placed over the dish, so that they can feed in safety. I always medicate the spring food given outside with salicylic acid solution.

The question of the foundation will, no doubt, be in some bee-keeper's mind. I have received enquiries as to which I consider the best. I have no wish to say as to which I make one rather, but I can speak as I find, and when I am asked, "Do you like the 'Weed' foundation?" I say, "Yes, I have tried the 'Weed' last season, and liked it very well." I also consider the bees reduced the "system" more in the "Weed" than in that of ordinary make. This season I hope to decide the matter for myself by further trials. I also hope to give the new deep-celled foundation a trial, if any is procurable. Our American brethren are still actively engaged in perfecting a foundation with deeper cells and thinner bases.

Adulterating Honey.—Our friends abroad are progressing in the framing and passing of anti-adulteration Acts, heavy penalties being imposed for selling honey adulterated with any other substance, even though the admixture may not be detrimental as food. We in this country want something of the kind to restrain the hand of the spurious honey-maker.

Assisting Increase in Stock.—Comparatively few persons are aware how much may be done by way of assisting stocks of bees to increase in number, in such a season as the present. It is quite a common occurrence to find six or seven combs of brood in strong hives at the middle of April, and only three or four combs so occupied in the second week of May if such stocks are left to themselves, whereas if they had been "nursed" without disturbing them, fed slowly and continuously, and kept warmly wrapped up, with entrances narrowed in cold and opened wide in warm weather, breeding would have been maintained all along instead of dropping off because of the failure of income, as it so often does. The point is, raising in the first instance with food enough and to keep brood nests supplied with food enough and no more, till winter-time comes round. If any honey at all is to be had outside, one hole of the hive will suffice, but should the bees be kept indoors by stress of weather, three holes may be used; thus, by keeping up a continuous supply of warm food, populations are increased by thousands daily, and little inducement is needed to make them enter surplus chambers and deposit therein all the honey gathered. We do not suppose that much supering will be required before the third week of May, except in some such spots as one we know of where about 500 acres of ground are devoted to Strawberry and fruit culture. In such favoured neighbourhood, some May sections will be possible, but they will be scarce this year.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY,	MAY 22—	Royal Botanic Society, Meeting.
MONDAY,	MAY 24	Lincoln Society (Anniversary), and West and Southern Counties Show at Southampton (5 days).
WEDNESDAY,	MAY 26	
FRIDAY,	MAY 28—	Royal Botanic Society, Lecture.
SALES.		
TUESDAY,	MAY 22	Special Sale of Orchids in Flower and Bud, at Protheroe & Morris' Rooms.
WEDNESDAY,	MAY 26	Lilies, Geraniums, Greenhouse Plants, Carnations, Herbaceous Plants in variety, &c., at Pro- theroe & Morris' Rooms.
FRIDAY,	MAY 28	Imported and Established Orchids, also Callas, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—66° 7.

ACTUAL TEMPERATURES:—
LONDON.—May 19: Max., 67°; Min., 44°.
PROVINCES.—May 19 (6 P.M.): Max., 64°; Hurst Castle; Min., 47°; Shields.

We hear a good deal about progressive evolution now-a-days, and it suits our complacency to dwell upon it. We look back to the days of our forefathers, and plume ourselves that we live in times when Palms and Pine-apples are sold on costermongers' barrows, and when many things once unheard of, or only as the luxuries of the wealthy, are now in common use. So far good, there has been marked progress in gardening as in everything else. But it is as well to recollect that reversion may and does occur as well as progress, and, therefore, that it behoves us, whether "practical" men or students, to ascertain so far as we are able the influences at work which will result in improvement, and those which, if unchecked, will tend to deterioration. Two articles in our last and present numbers illustrate very aptly the state of affairs. On the one hand, we have the Director of Kew tracing, with the aid of specimens furnished by Messrs. SUTTON, the progressive development of the Cyclamen; and, on the other, we have Mr. FRANCIS GALTON asking, for scientific purposes, what plants it would be most suitable to observe, and how to manage them, so as to bring about, in the shortest and most complete manner, the reversion to the primitive condition? We learn as much or more from our failures as from our successes, and on this principle we shall profit by the practical demonstration of the causes which lead to degeneration. Thus, an investigation which seems at first to be of a purely abstract character, is soon seen to be eminently practical.

Change of circumstances is followed by alterations in structure and appearance—this is what might have been expected; but there are other and very-marked variations which occur without, so far as we know, any correspondingly marked changes in the environment. In the progressive development of the Cyclamen, for instance, there has been no change of

treatment sufficiently great to account for the great variety that has ensued. A change presents itself, the quick eye of the cultivator notes it, favours its development, not so much by any active measures of his own, as by protecting it from injurious agencies and harmful competition. The nascent variation is thus allowed free play, and in this way the gardener is said to exercise selection. The cultivator cannot, however, create the variation, although he can and does control the circumstances which lead to its subsequent progress.

Cross-breeding and hybridisation are, of course, potent sources of change. It is said of the Cyclamen, that it is close-fertilised, that it has never been crossed by any other species. That may be so, but the term close-fertilisation is in this case not necessarily used in an absolute sense. It may happen that the pollen of a particular flower is applied to the stigma of the same flower, but more often it is the pollen from another flower of the same plant that is employed, or from a flower of another plant of the same strain or race. There are, therefore, various degrees of cross-breeding, and no one can demonstrate where cross-breeding ends and hybridisation begins. Some amount of cross-breeding may be expected even in the Cyclamen, but how far that amount is responsible for the changes that are manifest no one can say.

When we have allowed for changes of circumstance and cross-breeding in various degrees, there yet remains much variation, which, so far as we see, is not due to either of the causes we have mentioned. We call it spontaneous, innate, hereditary, a reversion, a property of protoplasm, and so, no doubt, it may be; but we must not allow these didactic expressions to conceal the fact that we are in reality ignorant, and that it behoves us in every way we can to lessen that ignorance. This is what Mr. GALTON proposes to attempt in his experiment.

He wants to breed back to the original form, and to ascertain by what stages and in what time the retrogression can be effected. A hardy annual is to be preferred, and one which has a well-marked variety—as, for instance, when the type has glabrous leaves, and the variety hairy ones, or one in which the variety is of dwarf habit than the type. From this point of view, some of the Sweet Peas seem to us adapted for the purpose, as the wild original plant still exists in Sicily. Dwarf and Runner-Beans might also be employed, but their parentage is not so definitely known. The China Aster is another good plant for experiment. The soil to be employed should be a light one, that is, one that is not rich in nutritive matter—a poor sand, or a sandy-loam to begin with—and employing in each generation a soil proportionately poorer, but not so destitute of food as seriously to affect the health of the plant. The water to be applied would of course be carefully measured, and the quantity allotted would depend on the character of the season.

By some such process of reduced nutrition and successive retrograde selection, that is by continuously selecting the worst forms instead of the best, Mr. GALTON would undoubtedly get something different from that which he started with, but we suspect it would be a depauperated form rather than a representative of the original type. This is precisely the point to be determined; and if any of our readers can furnish hints for the prosecution of the experiment to Mr. GALTON, they will be obliging him and furthering the cause of scientific horticulture.

In spite of what may be advanced against this system of garden decoration, on the score of inappropriateness and bad taste, it is certain that it hits the taste of the masses, and that it confers great pleasure to thousands who do not appreciate plants for their own sakes, but only as a display of colour or as parts of a design. It is certain, too, that a well-designed bed, which would be terribly out of place in a garden, or even in a park, when placed in a central situation in a town-square or before a railway station, or amid architectural surroundings, is not always so unharmonious and offensive as might be anticipated. Our continental friends indulge in these strange devices to a larger extent than we do, and however much we may dislike them as a rule, it would be affectation to deny their effectiveness in certain cases. Many are silly, glaring, and little better than outrages on taste. The worst specimens we have heard of are some in the United States. Still, it is not necessary they should be unharmonious and repellent; in the hands of a true artist they are capable of being rendered valuable object-lessons and things of beauty.

For those who have to construct these beds, and are at a loss how to carry out the work and what plants to select, we may call attention to the second edition of a book by Herr KARL GÖTZE. It is entitled *Album für Teppichgärtneri und Gruppenpflanzung*, or album for carpet-bedding and arrangement of ornamental plants. The fact that it is written in German by no means precludes its use by those not familiar with that language. In the first place, there are nearly 300 plans and 366 engravings, all of which are intelligible to gardeners of any nationality. Then there are copious lists of plants, arranged according to the use to which they may be put. These lists are very serviceable, and they afford an excellent illustration of the desirability of the use of Latin, rather than of vernacular names. As it is, the names are as intelligible as the pictures themselves; and neither Russian nor Turk need experience any more difficulty in the matter than the Germans, for whom the work is primarily written.

In order further to make the work useful to gardeners, a short garden dictionary is appended, giving the explanation of gardening terms used in Germany, France, England, Italy, and Holland. We have, therefore, no hesitation in recommending this volume to those of our readers interested in this kind of work, as they will find in it a larger number and a greater diversity of plans and illustrations than in any work of the kind that we know of. It may be had from Herr LUDWIG MÖLLER, of Erfurt, or from any foreign bookseller at the cost of a few shillings.

ARISTOLOCHIA GOLDIEANA.—One of the most extraordinary flowers now in bloom in the Victoria-house, Kew, is this West African species. Our illustration (fig. 116, p. 337) is about half the real size. The flower is naturally pendulous, or nearly so, the lower part of the tube is irregularly cylindrical, cream-coloured, smooth, and bent upwards nearly at a right angle into a funnel-shaped upper half. This part of the tube is marked with prominent purple ribs; and expands into a bowl-shaped three-lobed limb, strongly marked with purplish ribs, the three lobes prolonged into acuminate points; the interior of the bowl is yellowish, thickly marbled with velvety purplish-brown spots. The entire flower is as large as one's hat, and very striking in appearance, just one of those interesting plants which the Floral Committee would pass over as of no commercial value! Although in point of size, form, and colour, it is very attractive, we cannot say so much for the odour,

FIG. 116.—*ARISTOLOCHIA GOLDIENSIS* (HALF-SIZE) : FLOWER GREEN-COLOURED, WITH PURPLE RIBS AND SPOTS ON A YELLOW GROUND. (SEE P. 236.)

which is repulsive, though less so than in some other species. The plant has flowered previously in the Glasgow Botanic Garden and at Kew, but is so extraordinary and so rarely seen, that we need not apologise for repeating the illustration.

THE TEMPLE SHOW.—For the tenth time the Royal Horticultural Society will hold its annual flower show in the Inner Temple Gardens on May 26, 27, and 28. There is sure to be a grand display, judging from the large number of entries which have been received, and there is reason to believe that some of the exhibitors will show something original in the modes of displaying their plants. The judges will meet in the secretary's tent at 10.30 A.M.; the Fruit, Floral, and Orchid Committees will assemble at 11 A.M., and the show will open to the public at 12.30 P.M. An interesting feature of the catalogue will be an article on the "Royal Horticultural Society," from the pen of the President, Sir TREYOR LAWRENCE, Bart. Owing to the great pressure upon the society's officials, plants for certificate cannot be entered on the morning of the show. Messrs. H. CANNELL & SONS, of Swansea, will have a large exhibit of Gloxinias, Cannas, Calceolarias, Begonias, and Regal Pelargoniums. Messrs. J. VEITCH & SONS, Chelsea, intend to exhibit novelties from Japan, very fine Caladimms, Streptocarpus of a beautiful strain, &c. The cultivators of Orchids will come out in strong force, and many fine things may be expected from Sir TREYOR LAWRENCE, Baron SCHROEDER, Messrs. SANDER & CO., Messrs. VEITCH & SONS, and others. We are informed by the Secretary of the Royal Horticultural Society that Her Royal Highness the Princess of WALES has signified her intention to visit the show.

H.R.H. THE PRINCE OF WALES, who has recently visited Cheltenham, accepted, on behalf of the Princess of Wales, a basket of choice Orchid blooms, presented to His Royal Highness personally by Mr. J. CYPREA, of the Queen's Road Nurseries. The basket contained excellent spikes of *Odontoglossum crispum*, triumphans, and cirrosum, *Cattleya Mendellii*, *Laelia purpurata*, *Cypripedium Rothschildianum* and granle, and *Oncidium-obscurum majus*, &c. The presentation took place at the railway station, and the Prince graciously informed Mr. CYPREA that he thought the blooms very beautiful, and that he should have pleasure in conveying them home.

THE ROYAL SOCIETY.—Among the fifteen selected candidates for election this year we find the names of Mr. H. J. ELWES and Mr. G. R. M. MURRAY, the head of the botanical department of the British Museum, South Kensington.

HORTICULTURAL CLUB.—The usual monthly dinner and conversation took place on Tuesday, 11th inst., the chair being occupied by Sir J. T. D. LLEWELYN, Bart., M.P., and there was a good attendance of members. A paper was read by Mr. GEO. PAUL on the subject of *Amaryllis*. He entered at some length into their history and method of cultivation; he questioned whether a mistake had not been made in endeavouring to get the broad form of flower instead of the long tubular form of *Lilium longiflorum*, and thought perhaps something might still be done in that direction. Their slowness of increase militated against their more general cultivation. An interesting discussion followed, in which many of the members present participated; considerable surprise was evinced at the statement of the secretary, that he had had the hybrids of *A. vittata* raised by the late M. SOUCHEZ growing and flowering in the open air for the last twelve months; they were planted in the same situation as *Amaryllis belladonna*, i.e., in a border in the front of a greenhouse facing south, and passed through the severe winters which we have had of late without injury. A cordial vote of thanks was proposed by Sir JOHN LLEWELYN to Mr. PAUL for his valuable and interesting paper, and was carried with acclamation.

GHEENT QUINQUENNIAL.—Oh! how soon the years fly past! On our table lies the programme for the next quinquennial exhibition at Ghent in April next. Seven hundred and sixteen classes are con-

ferred. New plants, Palms, Orchids, Aroids, Cycads, Tree Ferns, Azaleas, Rhododendrons, &c., are among the principal objects of competition.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—We are requested to state that the fifty-eighth anniversary festival dinner in aid of the funds of this Institution will take place on Wednesday, May 26, at 6.30 for 7 P.M. (the first day of the Temple Flower Show), at the Hôtel Métropole, under the presidency of the Right Hon. Lord ROTHSCHILD. As a large gathering is expected on this occasion, the Secretary, GEO. J. INGRAM, 50, Parliament Street, London, S.W., will be greatly obliged if those friends who desire to be present will intimate their intention to him as early as possible, in order that the necessary arrangements may be made.

THE SURVEYORS' INSTITUTION.—The Annual General Meeting of the Institution, to receive the Report of the Council, and the announcement of the result of the election of officers for the ensuing year, will be held on Monday, May 31, 1897, at 3 o'clock. The prizes awarded to successful candidates, in connection with the recent preliminary and professional examinations and junior meetings, will be presented by the president at the Annual General Meeting.

VICTORIAN ERA FUND.—Mr. R. O. WATERMAN, Secretary and Treasurer to the Gardeners' Mutual Improvement Society, Woolton, Liverpool, writes:—"I might be allowed to state as a suggestion for the above what my committee propose doing. The committee of the Liverpool Horticultural Association have placed at our disposal tabling at their summer show, July 31 and August 2, at Sefton Park, where we hope to arrange an attractive exhibit of plants, fruits, flowers, &c. The proceeds to be devoted to the above deserving fund. This appears a simple means of raising a considerable amount if adopted throughout the country, especially near large towns, where flowers, &c., readily obtain purchasers. Exhibitors and other persons interested would willingly supply the necessaries, and this is especially applicable to Rose shows. If the committees of the societies are unable to make the necessary arrangements, the management could be handed over (as in this case) to some other society, or a few willing helpers.

THE COWTHORPE OAK.—Two young Oak trees were planted on Tuesday afternoon, the 11th inst., at Cowthorpe, near Wetherby, to commemorate the celebrated tree [figured in *Gardeners' Chronicle*, January 19, 1895, p. 73. Ed.], which stands there still, but is greatly decayed, and may not endure much longer. The old tree is of great girth, measuring more than 50 feet at 3 feet from the ground, and is probably the thickest Oak in the world. The young Oaks were raised from Acorns taken from the old tree by Mr. John Clayton, of Bradford, in 1893. The late Mr. Montagu, of Igouathorpe, approved of this method of perpetuating the memory of the wonderful tree, and kindly agreed to it before his death. At the ceremony of planting the trees, there were present Mr. CLAYTON of Bradford, Messrs. FARRAR & MILLWARD of Harrogate, Mr. CASS of Cowthorpe, and others.

THE THERMOGRAPH AT THE BERLIN EXHIBITION.—In his prospectus, the exhibitor, Mr. OTTO BOHNE, Berlin, S. Prinzstr., 90, says:—"The thermograph is a new instrument, registering the changes of temperature. Its appliance in various kinds of business has proved most successful, being also adapted to secure a constant and sure control over the heating of stoves, &c., and to furnish proof of any negligence which may have occurred at any time." The instrument may be connected with an electric bell, so that when the temperature is reaching maximum or minimum an alarm will be caused, no matter how great the distance of the instrument. No doubt for scientific experiments it will prove to be of great value. Its cost is £8. *Bechnick.*

"COTTAGE GARDENING."—The ninth volume of this very inexpensive publication is before us. Each number costs but one halfpenny, and contains eighteen

or more columns, and two or three illustrations. It is published weekly by Messrs. CASSELL, and is edited by Mr. W. ROBINSON.

CYCLAMEN LATIFOLIUM (*persicaria*, *Hort.*). On the 22nd of last month, MM. VILMORIN ANDRIEU ET CIE. are reported to have exhibited before the National Horticultural Society of France the wild form of *Cyclamen*, showing the degree of perfection attained in modern developments.

FLOWERS IN SEASON.—We have received several plants of *Myosotis alpestris gracilis* from Mr. F. C. HEINEMANN, seed-grower, Erfurt, Germany, a variety not much known in this country. The plant is of neat, dwarf, compact habit, well fitting it for market-work, dividing-lives and edgings to beds of other spring-flowering plants, table and room decorations, and other uses. The flowers are pale blue, small, and numerous produced. The plants sent had been lifted from the open ground, and potted, and sent off at once, travelling in capital condition to London.

THE ROYAL CALEDONIAN HORTICULTURAL SOCIETY has resolved to celebrate the Diamond Jubilee year in several ways in connection with its autumn show to be held on September 8 and 9 next. In the class for the most tastefully-decorated table of dessert fruit, a Veitch Memorial Medal will accompany the first prize of twenty guineas, and the second and third prizes will each include a Victoria Jubilee Medal. Similar Medals will be awarded with the prizes for the best groups of miscellaneous plants arranged for effect, the money prizes being exactly similar in value to those in the fruit classes. The exhibitor of the best-arranged table of various cut flowers will be awarded ten guineas and a Jubilee Medal; and the second and third prizes will also include such medals, but of differing value. A class in the vegetable section will be distinguished in precisely a similar manner. Furthermore, the Council has decided that after the expenses of the show have been defrayed, the surplus funds shall be devoted to charitable purposes directly connected with horticulture. We anticipate the show will be a very fine one.

THE ALPINE-HOUSE at Kew is now full of beautiful and interesting plants from the Falkland Islands, as well as from regions nearer home, such as *Oenium parviflorum*, a little gem, with prostrate habit, small circular rugose leaves, and pure white flowers; *Oxalis enneaphylla*, from the same region, with nine glaucous leaflets folding one over the other, and relatively large white flowers, is very attractive; *Ranunculus trilobus*, various *Androsaces*, *Ranondias*, *Haberlea rhodopensis*, *Cassiope fastigiata*, *Campanula thrysoidea*, *Arum albatipatum*, and various *Saxifragas* are among the plants we noticed in a hurried walk through. We strongly advise plant-lovers to pay an early visit.

THE QUEEN'S REIGN.—Mr. HENRY RUMSBY CANNELL, M.S.A., is to give a lecture, exhibiting tinder-box, flint, and steel, showing the old-fashioned mode of producing fire, explaining numerous alterations and events that have occurred; also the rise and progress of the people, and of the country. The proceeds are to be handed over to the Royal Gardeners' Orphan Fund, of which H.R.H. the Princess of WALES is a patroness, his Grace the Duke of BEDFORD President, and Mr. H. CANNELL one of the founders. Seventy children are at this moment receiving 6s. per week from the Association. Tickets, 6d., 3d., and 1d. each.

ORCHIS MORIO.—Mr. ENOLEHEART writes:—"I send you a small gathering of *Orchis morio*, that you may see how very pretty it is in some of its varieties. The pure white is fairly common in our pastures, the decidedly pink less so. It is curious that out of a very large number of spikes which I gathered over a considerable stretch of ground on Sunday last, every one had the pollinia of all its flowers intact, even spikes somewhat on the wane. The pollinia which are wanting in the flowers now sent have been withdrawn by myself. Has the moth or other insect which commonly fertilises this *Orchis* failed to appear here this season? The

weather has been sunny by day, and sufficiently warm at night to keep insects on the wing. In withdrawing the pollinia of *O. morio* by a sharp pencil thrust into the flower, I observe that their subsequent depression is less than in the case of *O. mascula*, if Darwin's drawing is accurate (*Fertilisation of Orchids*, p. 15), i.e., that they remain at a greater angle to the horizon. This means, I suppose, that the stigma of *O. morio* is higher above the head of an insect entering the flower than it is in *O. mascula*.

THE SOUTH AFRICAN FLORA.—A gentleman in the Cape Colony writes to tell me he is able to furnish me with seeds of every South African species, and will send me twenty packages of seeds every week. I beg to invite all interested in the very important, enormous, and most beautiful flora of South Africa to communicate with me on the subject immediately after reading this. *M. Buisson, Middlebury, Holland.*

DICTIONNAIRE ICONOGRAPHIQUE DES ORCHIDÉES.—A new issue of these useful illustrations of Orchids, accompanied by the little *Chronique Orchidicole*, has reached us, and found to be of equal importance to its predecessors. The genus *Cologyne* is commenced by the usual scientific description and table of essential characters, and plates of *C. cristata* and *C. cristata alba* given. Most of the other species illustrated are of the ordinary showy kind, the only one specially interesting botanically being *Lycaste l. siglossa*, a species not often seen in gardens. The others well illustrated are *Odontoglossum Rossei majus* and its variety *rubescens*; *Catleya Trianae* and its variety *alba*; *Dendrobium Warlianum*, and *D. W. album*; *Cypripedium Godseffianum* var. *Jupiter*; and *C. Spicerianum* and *C. S. magnificum*, neither of which by the way can the artist be accused of having "overdone."

SPRING - GARDENING AT BELVOIR CASTLE.

The woods around this famous place were fast putting on their spring mantle of greenery, and the beautiful gardens, unique of their kind in Great Britain, were looking their best, when after a lapse of eleven years we again visited it.

The genial guiding-spirit of the place, and part-creator of the woodland-gardens, William Ingram is, alas! no more, and another gardener has taken up his onerous duties.

If to Ingram much of the initiative in regard to the improvements at Belvoir is justly due, we must concede to the present head-gardener, Mr. W. H. Divers, the carrying out of much needed improvements in the management of the gardens, the vineries, pits, and plant-houses, a greater regard to cleanliness and orderliness, matters of first-class importance in any garden, and especially so at Belvoir. Unfortunately the pressure of the times is felt by Duke and peasant alike, and the inevitable reduction in the garden-staff has taken place here; still, it is at the present unaccompanied by any visible effect in the upkeep of the garden.

The Vines, which had been starved at the root, and unskillfully treated at the top, have much improved, although their great age might have tempted many a gardener to clear them out, and plant new ones in new borders, so generally unsatisfactory being the attempts made to put new life and vigour into almost dry bones.

There is, fortunately or unfortunately, as may be, a reverence at Belvoir for the antique, which extends to many things besides gardens and gardening, and the present Duke of Rutland being in favour of the retention of the old guarded Vines, they are making fairly strong wood, substantial leaves, and shapely bunches of medium size in all of the vineries. Mr. Divers, in improving the Vines, has relied upon frequent dressings of artificial manure, the securing of good drainage and applications of rich pasture loam and crushed bones. Very early Grapes are not wanted, so that the Vines are not distressed by hard

The area of 7 acres forming the vegetable garden was dug or trenched in every part, and numerous new beds were becoming visible, and old ones in process of being cleared off the land. This vegetable-garden, with its unusually high wall, rounded angles, and ornamental entrances, is, as all visitors to Belvoir know, a fine feature of the place. The walks, or rather roads, are of great width, the central one being not less than 20 feet, the side ones 12 feet. All are edged with Box, the formidable task of relaying which was recently completed.

Fruit trees of various kinds, dimensions, and ages, clothe the walls in countless examples, of which, with the exception of young ones of recent planting, were loaded with bloom in the case of the Pears, and with fruits in that of the stone-fruits. It is a work requiring much labour to cover and uncover daily the great area of wall planted with such kinds as need protection in the spring, and a simple plan is adopted, namely, to fasten "Frigi Domo" or close netting to the top of the wall, then place smooth quarterings under the coping and extending some 4 feet from the base, and sufficiently close together to prevent the material touching the face of the wall. The curtain is lowered and raised in great lengths by a man or two working from a ladder at the opposite side, or standing on the wide coping of the wall, and secured when not in use at the top—no rollers, rings, cords, and pulleys being employed.

In consequence of the great number of spring-flowering plants employed in the various parterres round the castle, and the necessity of having two-year-old plants in the case of *Polyanthuses*, *Alyssum maritimum*, *Arabis sempervirens*, *Heuchera sanguinea*, &c., and of dividing and planting out many other species to grow into serviceable stock for putting in the beds in the autumn, a considerable area of the vegetable garden is occupied with these spring beds. An acre or more immediately in front of the vineries in this garden is likewise planted with perennials and bulbs, and the collection is particularly rich in long oblong beds, with Box edgings, and narrow walks of gravel between. Immense lots of *Narcissus* and *Violets* are grown, the former for cutting and planting in the grass and the beds, and the latter for putting in the beds only. Those who have visited Belvoir may skip the next few sentences.

The site of the present structure on the top of an abrupt hill, once difficult of access on all sides, but now connected with the range of hills of which it formed an outlying spur by a wide and naturally-effected embankment, is about 470 feet above sea-level, and 250 feet above the level of the kitchen garden. From the terrace and windows of the castle beautiful and very extensive views, north and eastward—so far, indeed, as Lincoln and Newark, are obtained. From the earliest times it was selected as a place of strength, British, Roman, Saxon, and Norman having held it in turn as a fortified position, dominating a wide stretch of fertile country; and during the civil war, being held for the king, it withstood a siege of some duration, and only capitulated on being bombarded by a mortar brought for the purpose from Reading by the parliamentary troops.

On the north-east the ground is very steep, but it has been rendered easy of management as grass land by three wide and low terraces; and on other sides also, excepting that those are furnished with narrow winding walks and ancient specimens of Oak, that do well here on the tenacious earthy soil, common Yew, Portugal Laurel, and a wealth of exotic flowering shrubs.

Nothing that is ancient is to be found on the exterior of the castle, and inside there is but little, if we except a portion of the cellars. The present structure dates from the second decade of the present century, and was greatly injured by a fire in 1841 when approaching completion, many valuable articles, tapestry, books, &c., being destroyed, the loss of which was irreparable. This portion was soon rebuilt by the then possessor, but being constructed of a different kind of stone, it is easily distinguished from the other portion.

Close to the castle itself no gardening of any kind is attempted, if we make a narrow strip on a bastion enclosed with a low embankment wall on this side overlooking the woods and pleasure-grounds. This small garden was furnished at the time of our visit with a mixture of bulbs and spring-flowering subjects, the beds being bordered with ancient Box

edging 1 foot high and broad, the middle of which had been cut out, thus forming a flat top, a double line. The reason for this being done by Ingram might be found in the death of the central portion from old age. The position is a warm one, and vegetation was very forward, Roses of various kinds being already in flower, and a couple of big specimens of *Magnolia Soulangiana* formed shoots of white and lilac-colored flowers.

Amongst others on the higher wall of the bastion the following were remarked:—Several Figs, *Rosa Banksii*, which blooms abundantly, and is never cut by frost; *R. simplifolia*, *R. Gloire de Dijon*, *Catherine Mermet*, *Marshall*, *White* flowers; and others; besides *Chimonanthus fragrans*, of whose blossoms fell the air with fragrance in late winter; of *Jasmines*, *J. nudiflorum*, flowering for the second time this year; *Lonicera Standishii*, with flowers deliciously fragrant for a great part of the year, never producing many blooms, however, open at any one time; the highly ornamental *Callifera* *Myrtilifolia*, *Photinia arborescens*, the young leaves and shoots of which are of a rich reddish-bronze in this season, and the flowers white, coming in panicles; *Crataegus pyracantha*; *Ilex* in much variety; *Clematis*; *Cornus* in variety, including the rarely *C. aurea*; *Pyrus coccinea*, and others; *Malus baccata confusa*, a graceful, dwarfed, creeping plant with white flowers, the first noticed; *Stenactis*; and *Avara myriophylla*, an excellent plant for clothing a wall with bright shining green foliage.

On the slope at the foot of the outer wall of this outwork of the castle there grew, in the shelter of Big Yew trees, a rounded specimen of *Chaenactis* from the garden, three of the Spanish Whin about 1 1/2 feet high and 2 feet high, and a small plant of the Wig-bush *Ribes Cuscuta*.

By following the walk at the foot of this slope the towering side of the castle came into view, and turning to the left, at the end of the walk we entered the bordering of the castle garden. This small parterre, the first reached by anyone coming from the castle at this point, consists of a number of irregular-shaped beds, and some of regular geometric outline, a few of which are planted similarly in pairs. We visited the contents of some of these beds as they now and will continue to appear, but do not describe the contents of the beds, although differing in the kinds and varieties of the plants used to fill them, rely chiefly for effect on various *Aubrietias*, *Alyssum saxatile*, *Saxifraga muscoides* var. *Atropurpurea*, *Tulips*, *Fansies*, and *Primula polyanthus*. A big oval bed was planted with the rich-colored *Aubrietia ovalis* as an edging, one foot wide, the next a border of *Leichtlinii* as an edging one foot wide, the next a border of *Veitch's* strain of *Primula polyanthus*, followed by a row of *Tulip Keizer's Kroon*, intermixed with *Magnolia cordifolia purpurea*, and the central area with some dark red-bronze kind of *Wallflower*. As an example of another kind of planting, a narrow oval with high sides (2 feet high) had an edging of *Crataegus* for a border, next a row of the white variety of *Myosotis distillatoria*—a capital subject where a low white-flowered plant is a desideratum; then a row of the dark purple colored self-Fansy *Admiration*, then double red-edged *Tulips*, and behind these came *Saxifraga crassifolia* behind all the other edgings, and *Emmenanthe radicans variegata*, the central space being filled with what should have been the true Belvoir yellow *Wallflower*. A circular bed at one of the corners of this parterre contained *Myosotis alpestris Victoria* (which is a variety that flowers later than the *distillatoria*) intermixed with some *Primula polyanthus* and yellow *Fansies*, an edging 1 foot wide of *Aubrietia græca* giving the desired finish to the whole.

The beds we most admired were two of a star-shape, planted with *Flox* anemone, dotted over with white *Tulips*, bounded by a broad row of Gilbert's *Harbinger Polyanthus*, creamy white, with a yellow eye, and very early to flower; then came *Fansy Admiration*, followed by an *Aubrietia*, and lastly a row of a red Daisy.

As a variation of this design were two stars, in the centre of the pretty, fragrant, pale lilac *Flox* divaricata, the *P. canadensis* of some, with *Versailles* Brilliant *Tulips* intermixed, occupied the central area, followed by *Primula polyanthus* in a mixture of colours; then came *Skyrark Fansy*, a free-flowering variety, white with a blue edge, and lastly *Aubrietia Leichtlinii*.

A much-raised bed, with the sides faced with Ivy, was planted with *Skyrark* and *Chreden Purple Fansies*. These raised beds are the least pleasing, presenting, as they do, a tumsh appearance, with but little elegance, their height being out of proportion to the width. The parterre was finished on the upper side by a crescent-shaped bed of large *Flox* anemone, with the flowers from the earliest part of the year; and we noted *Franchis brenialis*, the leaves now dying down; *Emmenanthe*, *Magnolia ligulata*, the earliest species to blossom; *Myosotis*, *Arabis*, and *Boreocornium phagnaganum excelsum* in bloom at the present time. In the summer time *Hymea elegans* and *Chimonanthus* flowers continue the show. The late-flowering *Arduw Gem Fansy*, together with single-flowered *Tulips*, made a nice display.

One of *Leichtlin's Aubrietias* named Ingram is a fine specimen, the colour a bright rose-purple, and the flowers of nearly the size of *Versailles*. This fine variety, named by Royal Standard *Tulips*, had a rich effect. The late-flowering *Arduw Gem Fansy*, together with single-flowered *Tulips*, was permissible, but rather bizarre. *Flox* *divaricata* and *Tulip Couleur Cardinal* will not be, the latter scarcely to take rank with the colour out of the former. A second row to take rank with the white ones, was a fine example of *Magnolia multiflora* in flower. We noted a very beautiful object in the castle garden, and a hedge of *Kerria japonica*, an old-fashioned plant seldom given the position it

deserves in a garden, shut off the garden from an adjacent walk.

The Statuary Garden is situated on a lower level than the one from which we have just departed, and derives its name from some statuary representing the seasons, dating from the days of Queen Anne. To the right on looking down into this miniature garden is a fine specimen 70 feet high of *Abies pectinata* (Silver Fir). This parterre, lying deep down amongst tall trees, consists of a series of steps, the upper one formed of small oval beds filled with purple Pansies, red Tulips, Aubrietias, with Daisies forming the lines of division. The middle step consists of beds of white and blue-flowered *Myosotis* mixed with yellow Wallflowers; and the beds on the lowest step are planted wholly with Wallflowers. The prevailing tint is blue, and the effect in early morning or late evening very charming.

The Duchess' Garden, the one most remote from the castle, being about ten minutes' walk from the last, is situated in a curve of the hillside, and about half way down the declivity, with a rich foreground of woodland at a distance of 100 yards, and a precipitous bank at the rear, the middle distance being furnished with a rather intricate mass of flowering shrubs, slender Conifers, Birches, &c. It is very charming, unique of its kind, and almost inimitable, failing similar surroundings.

A walk skirts the uppermost series of beds, another running lengthwise at a lower level. A plan of this garden is given in the *Gardener's Chronicle* for April 10, 1880, p. 457, and we do not remark any alteration having been made in it since that time, the mode of planting the beds presenting very similar features. The newness of the surroundings, due to extensive felling, have wholly disappeared, and the exotic and native shrubs, as well as the masses of flowering in the moist, sheltered hollow. As in the other gardens, the prevailing tints are blue and purple, obtained by using extensively *Phlox divaricata*, *Aubrietias*, and Pansies. Wallflowers are used to impart lightness. A square bed, cut into four triangles by a cross, having a circle in the middle, that is, a green lawn of an irregular shape, that the areas are of equal length, was pretty. The filling of the triangles consisted of *Phlox divaricata*, *Aubrietia*, and red and white Daisies, with margins of golden *Pyrethrum* and *Arabis*.

The largest bed on this bank is planted in various lines of considerable breadth with the white *Myosotis*, *Alyssum*, *Scabellula*, white Pansies, yellow *Polyanthus*, *Phlox*, *anemone* and *divaricata*, and *Skyrlark* Pansy.

The lowermost series of beds are planted in similar way lines with *Myosotis alpestris* Victoria, a neat hilled, small-flowered variety, and a white form of it, a great similarity in the style of planting followed in the castle garden being remarked.

A pretty feature noticed in the Duchess' Garden was a horse-shoe-shaped bed filled with yellow Wallflowers, and edged all round with *Myosotis alpestris*. Amongst plants that have become naturalised in this part of the grounds requiring merely to be kept free of that encroaching to the gardening, the everywhere present *Goutweed*, are *Anemone nemorosa* fore-plein, and *A. Robinsoniana*, the first with white, and the second with light blue-coloured double flowers. *Heuchera sanguinea* continues to be used for its pretty dark bronzy-green leaves and light scented flowers, but not so largely as formerly. Several square patches of *Tussilago fragrans* now in full leaf may have pervaded the air heralding with the perfume of its blossoms early in the year.

Shrubs in flower at this point worthy of notice were *Azara microphylla*, just going over, the fragrance of the tiny blossoms being still perceptible; *Alnus incana* silver-cherry, the orange-colored flowers just opening; *Spiraea Thunbergii*, a very fine seedling *Rhododendron* with hundreds of corymbs of rose-crimson blossoms; *R. Falconeri*, a big plant, was covered with heads of white blossoms, and a nightingale hidden away among its branches was pouring forth floods of song.

Some large plants of *Camellias* were literally smothered with fresh as well as fading double, red blossoms. The beautiful scarlet-flowered *Rhododendron Thomsonii*, which had been loaded with blossoms, was just going over. A large number of plants of *Saxifraga petata* were showing for the flower. *Halaxia tetraetris*, seldom observed of large size, forms here a bush of considerable dimensions, as does *Acer polymorphum*; and *Arundinaria falcata* and *Bambusa Metake* grow vigorously, and large examples of both exist hereabouts.

The rock garden, made on the hillside at some little distance from this garden, and within view from it, is thickly planted with spring-flowering plants, Ferns, bulbs, &c. *Vesicaria urticulata*, very early in bloom and very free, and 2 feet in height; and *Veronica rupestris*, excellent for clothing rocks, were remarked, the latter not yet in flower.

Presently, all the shrubs must be cleared away, and its place occupied by the gaudier, and certainly less pleasing, flowering plants of summer. We had looked on the scene late in the day, when the sun was setting, and lengthening shadows fell across the glen; in the early morning, when the sun's rays gilded on flower and leaf, wet with dew, and at midday, both of all hours, give us those of early morning for viewing the spring flower-gardens of Belvoir Castle.

HOME CORRESPONDENCE.

THE RENAISSANCE OF THE HOLLYHOCK.—I am surprised that "D. T. F." should agree with me on so many points, and then put himself to so much

trouble to differ with me on one on which he seems a little rusty; namely, the raising of Hollyhocks from seed in Scotland. "D. T. F.'s" advice as to the treatment of seedling Hollyhocks may do well enough in the south of England. But when he comes to some of the coldest quarters of Scotland, where they are only from six to eight weeks clear of frost out of the fifty-two, and the thermometer goes down from 8° to 10° below 32°, Fahrenheit, almost every spring, he would find that seed sown in the open air in March or April would only produce small plants, and so weakly that they could hardly be expected to stand a severe winter. I have tried both ways, and have come to the conclusion that the best time to sow seed is in March, and in heat, and work on as formerly advised. I have hitherto practised with success what I preach. "D. T. F." seems to put great faith in Mr. Forbes' collection, and his methods of propagation. It would be interesting to know whether the cuttings are struck in heat, or out in the open air, and whether the budding and grafting are done out in the open air or not. From what I know of the climate about Hawick, I hardly think they are. Another thing in favour of seedlings is, that those who cannot afford to pay such large prices as are usually asked can, for a nominal sum, work themselves into a good strain of healthy plants. "D. T. F." seems to take objection to the Spruce Fir branches as protection during winter. I should not readily think it necessary to remind him that protection is better than cure. D. L. M.

FRUIT PROSPECTS.—All kind of fruit-trees, with the exception of Damsons, and one or two varieties of Plums, have been, or are still covered with blossom, and up to so late as May 10, the prospects of a good fruit season were very promising. Although one or two sharp frosts were experienced during April, very little damage appeared to have been done, with the exception of a few of the earlier bunches of red and white Currants, or the most exposed branches of these bushes growing in the outside rows of the fruit-quarters, and these bunches were denuded of half their blossoms. During the last few days the weather has been such as to make the earlier rose prospects extremely doubtful. On the morning of the 11th we registered 5° of frost; the afternoon previous we had a few falls of hail and rain, but with a good wind, the foliage and bloom were dry, or nearly so, before the frost commenced, therefore little or no damage was done; but during the evening of the 11th, it commenced to rain about 7, and continued until nearly 11. Almost immediately afterwards it began freezing, so by midnight the whole of the surface of the woodwork on garden-lights, &c., was coated with ice. Next morning we had registered 7° at 3 feet 6 inches from the ground. Of course it is early yet to speak with certainty as to the actual amount of damage the frost has done, but the Pears which were just setting appear to have suffered most, the ground underneath the trees being covered with the embryo fruits. The early blossoms of the Strawberry have had their pistils blackened where unprotected. Wall trees, which have had their coverings removed, are well clothed with foliage, which has protected the young fruit to a great extent, and which appear to have escaped so far any serious damage. The larger trees growing in the orchard, and more especially Apples, were, previous to the 11th, literally covered with their bright showy blossoms, but these are now of a dull sickly colour. The smaller trees growing as pyramids or cypresses do not seem to have suffered so much, as their blossoms still retain their healthy appearance. One can only hope that from the abundance of the fruit-blossoms on most trees, sufficient may have escaped to produce a fair crop.

G. Woodgate, Holleston Hall Gardens, Durlston-on-Trent.

FRUIT TREE GRAFTS FAILING TO GROW.—This season we find that the grafts on the Plum are doing very badly in this district [Northampton] owing, probably, to the harsh, drying winds that have prevailed. I have never seen the like before. Hundreds of grafts are quite shrivelled up. With showery weather some of these may come round, but it looks as if they would have to be cut off at the joints of all kinds. Will some of the readers of this paper inform me if such a state of things is common this year? H. K.

COCKROACHES.—In consequence of a paragraph that appeared in Answers to Correspondents, I have received a large number of letters from your readers. My efforts at clearing cockroaches were

confined to the Sheffield Workhouses, where the pest swarmed, and I was quite successful in clearing it. I did not contemplate making my remedy public, but owing to the many requests made to me I have arranged to put it on sale, and it can now be obtained from Mr. Hewitt, chemist, 66, Division Street, Sheffield; Messrs. Dunnell & Pater, chemists, Broomhill, Sheffield; and the Apothecaries Company, Virginia Street, Glasgow. All the tins bear my signature across the label, and I guarantee the efficacy of the paste in clearing cockroaches. Particulars are given in your advertising columns, and I shall be greatly obliged if you will kindly insert this letter, as I believe it will benefit your readers, and greatly relieve my correspondence. E. Howarth, F.L.S., Sheffield.

PHORMIUM TENAX AND VARIETIES.—Mr. Pettigrew's experience with seedling variegated New Zealand Flax is the same as mine, that is, that when any variegated variety forms seed, it is rarely if ever that a variegated or white seedling can be got to live, which is because there is little healthy sap or chlorophyll in the leaves. Plants raised from seeds that have been sown in the garden will often come with leaves quite green, that is, healthy, and from which all have doubtless been derived. *Phormium tenax* var. *atropurpurea* will sometimes come true from seed, and many, although taken from the same seed-plot, will be the true P. *tenax*. I have planted clumps of P. *tenax* variegata, *Colensoi*, and *Veitchi*, but in course of time most of them reverted to the original species. P. *t. atropurpurea* is, I think, the handsomest variety. W. O. Pota, Cork.

CYTISUS PRÆCOX.—In your issue of May 8, you have a note on *Cytisus præcox* x, in which the writer expresses his ignorance of its origin. It may interest him and other readers to know that it was found among a bed of seedlings of *C. purgans*, some thirty years since, by my grandfather, the late George Wheeler, of the Warminster nurseries, and I have in my possession a photograph of the original shrub. I cordially agree with "W. J. B." that this distinct early and free-flowering variety deserves much more attention than it gets, as for the edges of shrubberies and large mixed hedges applied to the same object than a good specimen simply covered with blossoms it is in mid-April. H. J. Wheeler, The Nurseries, Warminster.

ELWORM IN PASTURES.—I was surprised to see on p. 323 of last week's *Gardener's Chronicle*, Mr. J. Willis writing to the effect that small doses of certain artificial manures applied to pastures formed a remedy against elw-orm. Although Mr. Willis is a specialist on artificial manures, he has evidently had, if any, very little practical experience in destroying elworm pests. No doubt this is a bold assertion, but nevertheless it is true, as may be seen by following closely what he has said on the above subject, p. 323. Mr. Willis first of all informs us that, "if the elworm is in the pasture, the infested soil should not be used." I should like to ask your correspondent to what species of elworm his indefinite remarks apply, and also why the turf should not be used? There are very many different kinds of elworm found in England; some of them, however, do not attack or destroy any plants under the gardeners' care. If soil contained only harmless species of elworm, why should it not be used for growing plants? A few of the harmful species are as follows: *Tylenchus devastatrix* (stem elworm), which attacks Clover, Oaks, Potatoes, Onions, &c.; *T. obtusus* (stem and root elworm), which attacks Vegetable Marrows, Carnations, Melons, Dracenas, &c.; *T. triticeus*, found in the seeds of the Wheat plant; and *Heterodera radicola* (root-elworm), which attacks Lettuce, Beans, Cucumbers, Tomatoes, &c. The last-named is the worst of all the elworm pests, and if the turf were infested with this species, it ought not to be used for potting any kind of soft-wooded plants in unless the soil be previously disinfected. The other species named above are present in most turf- soil; indeed, we have never yet examined a soil which did not contain some elworm. I have seen it stated in many text-books on agriculture that kainit, basic-slag, and other chemical manures would, if applied, eradicate elworm from soils; but from many practical experiments carried out with the greatest care, it has been found that ten times the amount advised by Mr. Willis and the text-books writers will not do so! Mr. Willis further tells us to take some of the infested turf, mix with it kainit and basic-slag, and watch the result. This is all very well from a scientist's point of view, but what practical gardeners want to know is how much kainit and basic-slag to use per load of soil; and also

whether they (the manures) will kill the eelworm if used. When gardeners are compelled to, they can carry out the "watching for result" process without being told to do so; but Mr. Willis' advice would have been more valuable if he had first of all carried out the experiment, and then given us the results. There is still another sentence on p. 323 to which I should like to make a few remarks. Mr. Willis says that, "a little sulphate of iron for watering will assist the plants in overcoming the eelworm attack." It might do so, but what quantity are we to use? Perhaps it may interest Mr. Willis to know that in one experiment 82 ozs. of sulphate of iron in 12 cwts. of infested soil, and in another 1 lb. of sulphate of iron in 160 lb. of infested soil, did not affect plants or kill eelworm. Fearing I may be depending on your valuable space, I will leave the remedies we have found successful until a future issue; but before closing I may say that water at 130° Fahr. will kill eelworm, and if turf infested with this pest be treated with sealding water it will prove a cheap and effectual remedy in destroying eelworm. A *Notice*.

DARWIN TULIPS.—There seems to be prevalent a notion that the section of late-flowering single Tulips having the above appellation is of the late Charles Darwin's raising. That is not so. The raiser was Mr. Krelage, the well-known bulb grower, who, having evolved this beautiful section from out of others by intercrossing and hard selection, feeling that the section presented an admirable illustration of the progress of evolution, named them Darwin Tulips, in honour of the great apostle of evolution. The flowers of these Tulips have nothing in them that is quaint or singular, such as may be seen in the Parrot section; rather they are remarkable for fine root form, and singularly beautiful colours in exceeding variety. Having already Van Thols, Dutch, English, Parrots, late, and a numerous species, there can be no room for objection to the addition of yet a further section under the appellation of Darwin, and a section, too, that when well known promises to become most popular. *I*.

PREMATURELY-DUG BULBS.—In the few remarks you kindly published in the *Gardeners' Chronicle* of May 8, I endeavoured to explain how Mr. Joridan succeeded in conserving prematurely-dug bulbs in a manner at once simple, and devoid of much labour, and perfect as regards the means of retaining the names of the same. The thing in this matter of recently dug wild gardening is carried out at Royston's Park, I write in particular of the general excellence of the spring-flowering bulbs, and drew the inference that Mr. Joridan's new plan of treating his bulbs was a successful one. To whatever purpose the bulbs thus conserved are put, I am not able to state; suffice, that all that are there grown are worthy of admiration. Last week Mr. Jenkins asked whether I intended to tell the readers of the note, in all sincerity, that the best beds were obtained by the method of defoliation I had described. My former communication entirely negatives such a supposition. Is it necessary for me again to inform your correspondent that I was dealing with bulbs prematurely dug up? Can your correspondent show, by any possible amount of word-twisting, how any bulbs so dug up can be used for filling the beds the next year in anywise to resemble those specially prepared for what he calls the "best beds"? As the subject will not bear discussion, the oft-quoted "grain of salt" is not in requisition. Happily, I only endeavoured to describe the method practised by Mr. Joridan, and I thought out and practised the method myself; I should have been the more prominently subjected to the charge of plagiarism which is made against everything new, or which traverses old methods and practices. As the subject of "barbarous defoliation" has been mooted, I think it should not be allowed to rest without a few more remarks, albeit only scientists and those versed in plant physiology are capable of dealing with it in all its bearings. I may, however, ask at what stage of growth or age of leaf does defoliation become "barbarous"? In other words, when do leaves cease to perform their necessary functions? I refer now to deciduous plants. An Apple-tree, for instance, forms its flower-buds prominently whilst the summer's leaves are perfect, and before any signs of fading or disease are observable; the Peach-tree has its leaves brushed off with a besom whilst they are perfectly green and apparently full of vigour as they ever were; Potatoes may be dug when full grown, even if the skin should peel off them with slight rubbing, and they will keep as well and prove so floury as those left in the ground until winter, notwithstanding the fact that the

haulm is perfectly green. Again, Onion-bulbs do not seem to enlarge in circumference after their tubular leaves cease to grow; Dahlias and Jerusalem Artichokes are all but suddenly cut down by frost when growing vigorously, yet they produce, nevertheless, perfect tubers, and have continued to do so through a long course of years, still maintaining vigorous health and a capacity for propagation for an indefinite time. And bulbous plants, when do they cease to receive assistance from the leaves? Tropical bulbous plants have to make their growth during a short rainy season, for once that is past, the tropical sun soon lifts up all surface moisture wherein their shallow roots rest, then comes a sudden and intense aridity of the air and soil—yet these bulbous plants survive. When do Hyacinths and Narcissus leaves cease their office, obedient to the demands of the plants? Is it when growth, and with growth useful activity ceases, or do the leaves in decay feed the bulbs? When Mr. Jenkins can answer these questions, he will be in a better position to talk of barbarous defoliation. *William Earley*.

CATALPA BIGNONIODES.—Seeing in the *Gardeners' Chronicle* a record of an old Catalpa syriaca, and judging from the photograph, I think my tree far older than that of the one shown, and far bigger in the timber. I give the dimensions below, but am afraid to say the age after the assertion that the tree represented, if not the first, was one of the first imported to this country:—Girth 3 feet 10 in. from ground, where it divides into three branches, 13 feet 10½ inches; girth 7 feet from ground, first branch, 6½ feet; second branch, 6 feet; third branch, 4 feet 4 inches. Spread, east to west, 55 feet; north to south, 47 feet 6 inches. Height, about 37 feet. *H. T. Pitt*.

SOCIETIES.

ROYAL HORTICULTURAL SCIENTIFIC COMMITTEE.

MAY 11.—*Present*: Dr. M. T. Masters (in the chair); Mr. Douglas, Mr. MacLachlan, Rev. W. Wilks, Dr. Miller, Dr. Bonavia, Mr. A. Suttou, and Rev. G. Henslow, Hon. Sec. **Business.**—*East Trees*.—Mr. Roland Smith, of Shrewsbury, forwarded some living specimens received by him from Mr. J. Jones, Chelmsick Pools, Church Street. They were described as attacking Plum and Apple grafts, Roses and Raspberry buds. They proved to be *Otierrhynchus pipiens*. The trees and bushes might be sprayed, though a better plan is to shake the boughs over a large sheet of paper, in which they can be caught and then destroyed.

Birch Branch with Phytolacca.—Dr. Masters showed specimens illustrating the early stage of the attack on boughs by this insect. It is not often the commencement of the so-called "witches' brooms" can be detected as in this instance. **Abies bracteata.**—He also exhibited sprays of this hardening tree from Tortworth, remarkable for the silvery undersurface of the leaves, which are about 3 inches in length. It is a native of S. California.

Abies Menziesii.—He also showed a branch of this splendid timber tree from Vancouver laden with Catkins, from Tortworth (East of Dacot).

Flowering-shoots of the Eklivarillo (Sealling) Apples were received, remarkable for having no petals. They were sent from the Glestown Gardens, Ross. There were 600 bushes of twelve years' growth, all being similarly affected. No particular cause could be suggested.

Dr. Masters presented a single specimen of the flower of *S. incomparabilis*, of a somewhat novel character. The perianth consists of twelve pieces regularly arranged in "threes." The short cup-shaped corona, as well as the stamens, were totally absent; but the styles above the tube were free and petaloid, suggesting the normal condition in an *Asis*.

Scolytus (C)—Mr. M. Taylor, of The Gardens, Pembidw Hall, Nanncery, sent some remarkable specimens of a fungus, consisting of large branching lumps, which appeared in a Mushroom-bed. They were forwarded to Kew for investigation.

Method of Grafting.—Mr. ROBERT SMITH, of Bradwell Villas, Bishop Street, Sturbury, sent a number of specimens of grafts, illustrating a new method. This being, that in preparing the scion, while one "tongue" is inserted as usual, the opposite half of the scion is carried over the flat top of the crown, and inserted on the opposite side, or two grafts may be thus inserted on opposite sides of the stem, the result being, as shown in the specimens sent, that the summit is completely covered in with new growth. This was seen in small specimens of whip-grafting, but none were sent to show how far large crowns would become covered. Another advantage arose from the new method of preventing loss of grafts by wind breakage, for it thus gave a better and stronger union. It was thought by Mr. Douglas that it was a decided improvement upon the old method, as long as the scion and stock were of the same size; but further information was desirable as to the success

when the surface of the stock neck exceeded that of the scion. See *Gardeners' Chronicle*, 1874, vol. ii., p. 359. **Double White Auricle.**—Mr. R. DEAS sent a plant which was the result of fifteen years' selection from a single white variety; the petals were not of a pure white, but slightly yellowish-green tint.

THE TULIP CONFERENCE AT REGENT'S PARK.

At the Conference held on the 12th inst., in connection with the exhibition of Tulips, which was reported in these columns last week, there were read the following three papers:—1, "The History of the Tulip," by Mr. J. W. BENTLEY; 2, "The Hybridisation of Tulips, and Raising of Seedlings," by the Rev. F. D. HOMER; and 3, "The Cultivation of Tulips," by Mr. C. W. FOSTER. The meeting was held in the Museum, and the attendance was less than two score. The chair was taken by Mr. J. JO. WENNER, who, in opening the proceedings, addressed to the audience a few words of encouragement in their efforts to popularise in the Southern Counties the culture and love of Tulips as they are regarded by the florists. He spoke of certain indications of a re-assuring kind that he had observed, and incidentally mentioned that the late Dr. Hogg, who had acquired a considerable collection of Tulips, had once given the sum of £20 for a single bulb.

THE HISTORY OF THE TULIP.

Mr. J. W. BENTLEY, Hon. Sec. of the National Tulip Society, and an authority upon the history of the florists' Tulips, gave a brief discourse upon their history since, in 1559, they were cultivated in Angsburg, according to Gesner, which history has been perpetuated by the Tulips Geneeriana. The regard held by the Turks for the Tulip no doubt existed for years before the love or knowledge of them travelled westward. In 1577 Tulips had reached England, and little time elapsed before the English florists had raised many seedlings of their own. In 1618, thus, Sir J. Parkinson was familiar with 174 varieties, and in 1665, in Ray's catalogue there were 184, whilst in a subsequent edition there were 300 recorded. The Tulip mania, with which everyone is more or less familiar, was passed by the lecturer in a few words, it was merely a form of gambling. Early in the eighteenth century, viz. 1710, The States-General ridiculed at the Tulip raisers, on account of the excessively long names given by them to the varieties, and the same paper quoted a declaration by a florist to the effect that his bed of Tulips was of more value than 100 acres of the best land in the country. Many of the Dutch Tulips were thought by Mr. Bentley to have been French seedlings, but the French were so frequently embroiled in warlike proceedings, that the cultivation of them was more common in Holland.

At the commencement of the present century, Tulips were cultivated in considerable quantities in the Netherlands, where Dutch varieties; but immediately after this time the British raisers bestirred themselves, and in 1820 the position of British Tulips was assured. Until years later, the southerners had the business in their own hands, but after 1840 the midlands caught up the declining interest in the south. Since then the "tulip" has been in a measure lessened, and what interest has survived has gone north. There was little seed saving and Tulip raising carried out at the present time, but the work is still practised by the Rev. F. D. HOMER, and by Mr. JAS. THURSTON, CANOEIC, Staffordshire, the one of the objects of the conference was to stimulate an interest in the cultivation of Tulips in the south, and he hoped it would be successful. The English florists' Tulips were later in flowering, larger, and of better form than Dutch roses. The flower-stem should be sufficiently strong to support the flower erect. The six segments should be broad, rounded, equal in size and shape, that when expanded would form half of a hollow cup. The florists' regulations as to colour were next given. The base should be pure white or yellow, stemms pure as base, and anthers black and black (see report of the show in last issue, p. 327).

The characteristics of the roses, and hybrid-men were then briefly discussed. The biazares have a yellow ground, with brown or blackish markings, and are very vigorous. Roses and hybrid-men have a yellow ground, but in the former case the markings are of rose, red, or crimson, and in the latter of purple, black, or violet. The secdling form of the flower before it is "bred" or "retified" is known as a "breeder." After it has broken into feather or flame it is retified, and is a flamed or feathered rose, biazare, or hybrid-men, as the case may be. The differences between the branched flame and the marginal feather colour on the segment is well known. Mr. Bentley was unable to suggest any explanation of the reason for the retification, except that it was evidently a step in their insuration or history. Retified varieties could be propagated truly by offsets. A good strain was necessary, even in the case of good varieties for these differ much. The best flowers as breeders were often found in the retification, and a variety of poor colour when a breeder often makes a desirable retified variety. Seclion was a variety good in all three classes, but this was the case in Sir J. PAXTON, either as feathered, flamed, or breeder. Dr. Harly and Modesty were good in two, and the flower of Seclion in three. The retification, and a variety of other flared. So that the grower had experienced of various kinds; indeed, it was this succession of anticipation, disappointment, and unexpected delight that made the study and culture of Tulips a never-failing source of interest and pleasure.

THE CULTIVATION OF THE TULIP.

Mr. C. W. NEEDHAM, Hon. Treasurer of the National Tulip Society, commenced his practical paper by remarking that in almost all descriptions of soil and locality the Tulip would exist and produce a floral display, but in order to obtain perfect flowers, the plants need careful cultivation and a perfect attention to small details. The position of the beds should be sheltered a little from the east and north. The beds should be 4 feet wide, well drained, and raised 6 or 8 inches above the level of the ground. If not well drained naturally, it would be well to take away the soil to a depth of 2 feet and put in a layer of rough rubble, and so drainage water should be carried with one that will conduct the surplus water some distance away. Ordinary well manured soil from the kitchen garden was an excellent medium for the bulbs to grow in, and it should be porous rather than stiff. Old turf that has been stacked a twelvemonth was also especially suitable when available. The bulbs should be put in rows across the bed about 6 inches distant each way; or if the object was to provide a floral display only, they might be planted at distances of 4½ inches. If the varieties were similar, two bulbs might be placed in a hole. When the soil is finished, the bulbs should be covered by a depth of 4 inches. If it be necessary to add manure, it is best applied as a top-dressing, using thoroughly well-decomposed manure for the purpose. It is an advantage to change the soil each season where this is practicable, and would that had been richly manured for a preceding crop is best, as it would require no additional manure at time of planting. If a little stimulant is required, moderate applications of nitrates, superphosphate of lime or kainit are best. In order to obtain pure, perfect blooms for exhibition, some growers found it to be an advantage to grow the bulbs alternately strong and weak. Every other year they would be cultivated in what is termed a "fat bed." Grass-feeding was certain to tend to coarseness in growth and in flower. The old growers used to talk of "staving their flowers into purity."

The correct time to lift the bulbs was when the stem was drooping, and would bend double without breaking. Great care was necessary to ensure that the bulbs were dried in a cool place. On account of the bulbs being allowed to be burned by the sun. Enthusiasts would require luck with divisions at some distance apart, in the order the bulb was planted in the bed, so that when the boxes were full the bulbs would be placed exactly as before lifted. In any case, it would be necessary to take care they were stored in a suitable position, and in such a manner that their nomenclature was not disarranged, and their identity thereby lost. The Tulip-grower required a book, in which he would enter the characteristics each variety displayed, with such observations upon them as circumstances suggested. At the end of the season, the collection would be weeded out according to the register in the book.

The chief source of injuries to Tulips whilst growing was hulkstoms, and bright sun succeeding frost. If the flowers were desired without blench, it would be necessary to protect them by blinds of stiff tiffany or netting, which should be drawn across the beds immediately above the plants. It was a critical time for the Tulip when the bud was just above the ground—it was often ruptured by frost at that period. Exhibitors frequently protected their Tulips by movable frames, that could be placed over them at critical periods, and removed for different purposes at other times.

HYBRIDISATION AND RAISING OF SEEDLING.

A very interesting paper by the Rev. F. D. HORNER upon this subject was read by Mr. BENTLEY. The reverend gentleman commenced by insisting upon the condition necessary in the hybridisation of any plant with a view to obtaining improved progeny, viz., that of parentage. In the selection of parents, much thought and care were essential. The hybridist need not be careful to select "rectified" varieties only, as breeders were just as good, and, indeed breeders generally carried more seed than a rectified variety.

Then Mr. Horner enumerated the characteristics desirable in a good Tulip. Form and colouring were such necessary considerations, and neither need be given the precedence over the other, but there was further room for improvement in form, such as in perfecting the roundness of the cup, increasing the shoulder, and the breadth of the segments, also in clearing the ground colour, and in improving the markings.

In order to accentuate the class distinctions in the florists' flowers, it was essential to use only pure blood, i. e., to cross bizzars with bizzars, roses with roses, &c., otherwise flowers with indefinite and undesirable markings would result. Before any flower is fertilised, it was necessary to see that the stigmatic surface was in condition, and that it should be guarded by a shield of cotton-wool, as well from the pollen of the same flower as from that of others that might be conveyed by bees, &c. This shield would have to be removed when cross-fertilisation was to be effected, and this cover, the stigma might be again guarded with a new shield of the same material. At the time the bulbs are usually lifted, the new bulb attached to a plant that has been cross-fertilised may be detached and lifted, and reared as ordinary ones. It has been no point in the development of flower or seed. The seeds are best sown as soon as ripe, or early in September, in boxes or pans, under glass, if preferred, or in

the open air, covering them about a quarter of an inch deep. If the seed is not sown until February, the seedlings will be up in May. They first appear similarly to an Onion, with one leaf only, and though increasing each year in size, as the bulb increases also, one leaf only will be produced until the bulb has reached its age to flower, which will vary from four to seven or eight years, according to whether the bulb produces a "dropper bulb" or not after the fourth year (see fig. 117). If it produced a "dropper bulb" the flowering stage is considerably delayed. Seedlings should be selected as soon as possible, though it was not always advisable to pass final judgment upon a variety for the first few years. All seedlings exhibiting poor form in the flowers should be destroyed before they have become "rectified." If it had been strictly done in earlier years, there would now be fewer flanged and feathered varieties with attenuated petals, possessing little to recommend them, except satisfactory markings. Generally, the bizzars showed the greatest development at present in form and markings.

in the season his Snappragons (*Astrichinus*) were attacked by a disease caused apparently by the same fungus (?)

Mr. KREBAGE, Haarlem, remarked that in Holland the fungus disease had been observed, and that it was shortly to form the subject of a scientific enquiry, but in the meantime cultivators were of opinion that it was the result of a soil possessing an insufficient quantity of calcium or lime.

Mr. R. DEAN said in Belfont, Middlesex, he had been unable to grow certain plants owing to fungus attacks, and it appeared that if a grower had there was something that tended to produce a disease in Sweet Williams, for they would not succeed there.

Mr. CHATER thought that the trouble was resultant from damage only.

The CHAIRMAN said that it appeared to be the same in the case of the Tulip diseases they had found it in many others. The best thing to do was to make the culture as perfect as possible, to keep the plants in such perfect health that the spores of a deleterious fungus could not affect them.

Mr. DEAN subsequently differed from Mr. Needham in the necessity of the bulbs should be placed in the beds 9 or 4 inches apart was quite sufficient, and the leaves then served to protect the plants in some measure from hail and other injury. At Long Ditton the best results had followed moderately close planting.

Mr. CHATER was of the same opinion as Mr. Needham, and favoured more sparse.

A question was asked as to whether it was not possible to give some explanation of the change described as "rectification," but beyond the statement that the "broader" stage was an immature form, none was given of the cause of the change. There was not even an intelligent theory. Mr. R. DEAN asked Mr. Bentley if he had ever known of a "rectified" flower reverting to the "broader" form, and in reply the latter gentleman stated that they so far lost their character that the base colour changed and was diffused, but that in all cases he had observed the feather or flange could still be seen, and the deterioration was due to gross feeding. Mr. DEAN said his experience had been similar.

Mr. Krebage having been asked to explain the meaning of the word "byblenem," said that in England the meaning of the word was imperfectly known. "Byblenem" was plural and meant several, the singular being "Byblenem." It was difficult to explain the meaning the word had, but literally it was "second section of the stem." Its meaning was secondary to "first," and he supposed that at some time this class was considered a second section or class. Asked by Mr. DEAN if in Holland the Tulip bulbs were accustomed to grow "droppers" (see fig. 117), Mr. KREBAGE said that botanical species occasionally did so. Such varieties as were in the habit of producing them were planted over a hard bottom of stones. The florists' Tulip, a seldom "dropper."

Votes of thanks to the Chairman and Essayists concluded the proceedings.

CAMBRIDGE PHILOSOPHICAL.

At a meeting held on Monday, May 10, 1897, Professor LIVINGE, Vice-President, in the chair, the following communications were made to the Society:—

I. "Observations on Stomata by a New Method," by Mr. FRANCIS DAWSON, President.

The method consists in the use of "Chinese sensitive-leaf," i. e., thin sheets of horn treated in a special manner. When a strip of this substance is placed on the stomatal surface of a leaf, it gives evidence of the condition of the stomata by its movement. If they are open, it curves away from the source of moisture; if shut, it remains stationary. By means of a simple apparatus, the degree of curvature of the horn is recorded. All the ordinary experiments with stomata can be easily and rapidly shown with a hygroscopic of this sort.

By taking readings at regular intervals the diurnal course of the stomata can be studied; in this way it has been shown that the nocturnal closure of the stomata is a periodic phenomenon like the "sleep" of leaves.

A number of observations were made on the effects of the withering of leaves on the stomata; it was shown that while the stomata of certain species simply close as the leaf withers, in others the first effect is a well-marked opening. This fact is of importance in connection with the stomata of the stomata, since it indicates the sense which the pressure of the surrounding epidermic cells has on the guard-cells.

It was shown that many plants open their stomata in long-continued darkness; this fact bears on the mode of action of the guard-cells, since it shows that they do not (as is often asserted) lose their turgescence when the assimilation of CO₂ is prevented.

II. By Mr. Bateson: "Notes on Hybrid Cinerarias, produced by Mr. Lynch and Miss Pertz."

It is stated by many writers that the garden cineraria arose as the hybrid offspring of several species of *Senecio* from the Canary Islands. This statement has been questioned by Mr. Theobald Dyer on various grounds. The author exhibited hybrids raised from *S. cruentus*, *S. multiflorus*, and *S. Heritieri* (banatus) raised in the Cambridge Botanic Gardens by Mr. Lynch and Miss Pertz, which illustrated the very great variability which appears in the offspring of the various crosses. In particular, specimens of *Heritieri* \times *Senecio* and of the reciprocal cross were produced, showing excessive variability, and proving how greatly the peculiar characters of *Heritieri* may be obscured in the offspring, even of the first cross. Five specimens of multiflorus \times *Heritieri* \times *Senecio* were exhibited, each of which was exceedingly distinct from the others. Experiments had entirely confirmed Darwin's observation,

FIG. 117.—TULIP WITH "DROPPER" BULB.

The New Bulb is placed at the bottom of a tube or sheath prolonged downwards.

(See Report of "Tulip Conference.")

THE DISCUSSION.

A considerable discussion was engaged in by several of the gentlemen present, the greater part of which had reference to a disease by which the plants are sometimes attacked. Mr. Wright was surprised that more had not been said by Mr. Needham respecting the disease, and after referring to many instances in the south where it had done much mischief, invited the latter gentleman to inform the conference whether it was prevalent in the north, and if so, if the cultivators there had found means to prevent it becoming an epidemic. Mr. Needham replied that he was unaware that the disease had been so common among northern collections as it was in the south. From the appearance of diseased plants in various parts of Tulip-growing counties, they were convinced that plants were not attacked by the fungus before the epidemics had been broken by hail or frost, or some other cause. They admitted, however, that when the fungus had obtained a footing upon such a plant, the spores from the same were afterwards sufficiently strong to successfully attack a healthy and unmanured plant. Mr. BENTLEY replied to much the same effect. Mr. W. BARR also attributed the fungus to be an after-result of damage to or weakness of the plant. A gentleman remarked that his Tulips were attacked by a fungus in spring that worked much injury upon them, and that later

that Cinerarias are self-sterile in a high degree. They hybridise, on the contrary, with great readiness. An accidental hybrid between Herford's garden Cineraria 2, and the reciprocal were taken, and the two plants being quite unlike each other. One seedling multicaulis x garden Cineraria 2, had been produced which was almost entirely female, a few anthers only appearing in later inflorescences. These experiments were to be continued, but so far as they have gone they have been very interesting, and show that the Cineraria was a hybrid between several species, cruentata, floridica, and probably multicaulis being among them. The two first are named by most writers as probable parents.

ROYAL BOTANIC.

MAY 19.—The annual summer exhibition of the Royal Botanic Society was held on Wednesday last in the usual spot in the society's gardens at Regent's Park. In comparison with the display last year, the exhibition recently held was not weaker; in comparison with that it should be, however, seeing there are upwards of twenty classes, it was unsatisfactory. The society will probably have some difficulty in restoring the popularity of this show, seeing that the Temple Show is now so great a success, always at a date but little removed. Mr. Sowerby is, however, making efforts to bring about this result, and if the best methods are used, more or less success will assuredly follow. The comparative absence of competitive collections was in some measure atoned for by the trade displays, and though small, the exhibition was a pretty one, and being held in most auspicious weather the visitors to the gardens were numerous.

Below we have noticed the exhibits other than competitive.

HONORARY EXHIBITS.

Exhibits of Roses were made by Messrs. Wm. Paul & Son, Waltham Cross, and Mr. W. A. Wood, Waltham Cross, and at Waltham Cross. Messrs. Paul's collection was a very fine one, and exhibited a careful arrangement. Standards or tall plants with furnished stems of such varieties as Crimson Rambler, Claire Jacquier, Pride of Waltham, and White Lady, were dotted among the well-flowered dwarf plants of many varieties. Boxes of cuttings of blooms and plants of Adiantum Ferns gave a nice facing to the group. The new Tea Rose Enchantee was represented by some very pretty flowering sprays of pale flesh coloured bloom. Mr. Russell's exhibit included, in addition to plants in pots and cut blooms in variety, a few dwarf plants in flower of the new and vigorous growing variety Mrs. Russell.

Mr. CHAS. TURNER, Royal Nurseries, Slough, made a display with well flowered plants of desirable varieties of Indian Azaleas, interspersed with a few Spruces.

New or interesting plants from Mr. W. PULL, 556, King's Road, Chelsea, included Anmia rotundifolia, noticed at the Drill Hall last week, a variegated variety of Ficus radicans, Asparagus Sprengeri, Davallia eppihyia, and Draecena rex, having broad leaves, widely margined with yellow.

A very commendable group of miscellaneous plants that might have been mistaken for one from Messrs. Laing or Peck, was exhibited by Mr. H. SCOTT, 4, Campbell's New Cross, E. of the Holmes, Regent's Park. It was staged with considerable taste, though a few of the plants might have been disposed more effectively. Mr. Scott also contributed a group of Pelargoniums in flower.

A display of herbaceous Calceolarias in bloom was made by Mr. JES. R. BOX, West Wickham and Croydon. The flowers denoted a good taste.

Hardy Rhododendrons in wickham varieties were shown by Messrs. J. W. WATERER & SONS, Ltd., Bagshot, Surrey. The plants were from 2 to 3 feet in height, and well flowered.

Messrs. T. F. RIVERS & SONS effectively ornamented one of the half circle little monuments with a group of Nectarine and Peach trees in pots, all of them almost perfect in appearance, and splendidly crested with handsome fruits.

Double-flowered Begonias were shown by Mr. THOS. S. WARE, Hale Farm Nurseries, Tottenham, in a few choice varieties. The Jubilee Begonia is a pretty flower with salmon scarlet outer petals, and white centre; Prince of Wales is a striking showy scarlet, with a small pure white centre, being a new break in this section; Golden Queen of England is a good smooth-petalled Camellia-like flower of pleasing tint.

Messrs. S. RIVERS & CO., Watford, had tasteful floral arrangements of diverse description.

An exhibit of fruit, vegetables, and flowers grown in the vicinity of Regent's Park by Mr. KELL, gr. to Mrs. ANSON, was exceptionally commendable as being from a local garden. This included a couple of Nectarine trees in fruit, a couple of dozen well fruited Strawberry plants of the variety Royal Sovereign; Peas, Sutton's Seedling Marrowfat, ready to gather; French Beans in a similar stage, and some Goshoms, &c.

A fine display of Tulips was made by Messrs. P. BARR & SONS, King Street, Covent Garden, London; a great many of the late-flowering varieties were represented in excellent condition in this collection. Several other species of hardly any name were included, also, such as Prince of Orange, a very brightly coloured flower of large size. A few varieties of the florist's section were exhibited to name upon trays. Altogether a very bright exhibit was made.

An exhibit of Mr. H. O. TANSHER, 106, Brimpton Road, S.W., illustrated the systems adopted in Japan of arranging cut flowers and foliage in positions as if growing.

Obituary.

MR. DUNCAN MCELLEAN.—We note the death, on April 19 last, at the age of 85 years, of Mr. Duncan McElean, for many years superintendent of the Glasgow public gardens. The deceased was a native of Luss, Dunbartonshire, a place famed for the beauty of the surrounding landscape, which must have awakened in him a taste for landscape gardening that he carried out with so much success in the parks of the northern city. He was appointed superintendent of the parks in 1853. At that time Glasgow possessed only one park, The Green; but in 1852 the corporation had purchased the land of Kelvin Grove for the purpose of a public park.

Sir J. Paxton was consulted and furnished a plan for laying out the ground, and the carrying out of the same was entrusted to the newly-appointed superintendent, and he performed the work in an excellent manner. Four years later the Queen's Park was laid out according to plans made by Sir J. Paxton; Alexandra and Maxwell Parks were also under his charge, the former having been laid out by him, and the latter much improved after it came under his care. After forty years' active service, Mr. McElean retired in 1893, and at that occasion his friends presented him with this portrait, which now adorns the walls of the Corporation Galleries.

MARKETS.

COVENT GARDEN, MAY 20.

Table of market prices for various flowers and vegetables. Columns include item names, quantities, and prices. Items include Anemones, Azaleas, Carnations, Eucharis, Iris, Lilium Harrisii, Lily of the Valley, Mignonette, Maidenhair Fern, Marguerites, Mignonette, and various sprays and bunches.

FRUIT.—AVERAGE WHOLESALE PRICES.

Table of average wholesale prices for various fruits. Columns include item names, quantities, and prices. Items include Apples, Nuts, Cob, Peaches, Medium, Second, Pine-apples, Chael, Strawberries, Grapes, Muscats, Peas, Artichokes, Apples, Currants, Cauliflowers, Cucumbers, Green, Horse-radish, Mint, Mushrooms, and Potatoes.

VEGETABLES.—AVERAGE WHOLESALE PRICES.

Table of average wholesale prices for various vegetables. Columns include item names, quantities, and prices. Items include Artichokes, Apples, Cauliflowers, Cucumbers, Green, Horse-radish, Mint, Mushrooms, and Potatoes.

POTATOES.

Finest quality standing colour have advanced a shilling; trade very dull for second-rate samples; Dunbar Main crop, 10s. 6d.; Saxons, 7s. 6d.; Glancie, 6s. 6d.; Main crop, 5s. 6d.; do., Giants, 5s. 6d.; do., Saxons, 4s. 6d. to 5s. per ton. Curary, now 13s. to 15s.; Malta, 10s. to 12s.; Jersey, 10s. to 12s. John Bath, Wellington Street, Covent Garden.

PLANTS IN POTS.—AVERAGE WHOLESALE PRICES.

Table of average wholesale prices for various plants in pots. Columns include item names, quantities, and prices. Items include Adiantum, Aspidistra, Azaleas, Calceolarias, Cinerarias, Draecena, Erica, Evergreen Shrubs, Ficus, Ferns, Fuchsia, Genistas, Hidcotyles, Hydrangeas, Lycopodium, Lobelia, Magnolia, Palms, Pelargoniums, Poinsettias, Primula, Spina palmata, and various sprays and bunches.

BEHINDING PLANTS AND ROOTS FOR THE GARDENS in variety coming very good.

THE WEATHER.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Days above and below 42° Fahr. "Days below" continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

Table of weather data for the week ending May 19, 1897. Columns include Date, Day, Temperature (Day, Night, Accumulated), Rainfall (10ths, Ins.), and Brioist Sun. Data is provided for days 05 to 19.

The districts indicated by number in the first column are the following:—

- 0, Scotland N. Principal Wheat-producing Districts; 1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S.; 6, Principal Grazing, &c., Districts, 6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; *Channel Islands.

ENQUIRY.

"He that questioneth much shall learn much."—Bacon. WATER-LILIES DYING OFF.—A correspondent sends the following communication, together with a large mass of Water-Lily root. "The root sent is that of the common Water-Lily. I don't know what is the matter with it. I planted a dozen of them six years ago, which grew wonderfully till this year. I have examined them at various times, but I can find no trace of growth. [There are a few healthy buds visible. En.] The pond is formed in a peat bog, the bottom of it being reat, accumulated mud, and vegetable matter; the water, which is of good quality, is furnished by a spring, and the depth in all parts of the pond is 2 feet, and width 70 yards by 30 yards. The pond is much infested by water-rats; there are also a few ducks on the water. Last year we had a pair of swans, but as soon as the flowers of the Water-Lilies made their appearance they gobbled them up, so we had to shift the swans to another pond in the locality. Some persons think that it is the rats that are eating the Lilies, others that the ducks are the delinquent. I have watched them both, but could not detect either in interfering with the roots. I shall be exceedingly thankful to have the mystery unravelled."

NOTICES TO CORRESPONDENTS.

APPLE SHOOTS: J. W. The buds had partially become fruit-buds, but from some climatal or other circumstances, they, as it were, altered their mind. Thus the half-and-half character of the development.

A JOB OF RENOVATING A SMALL GARDEN: N. M. The charge seems to be by no means excessive, and is less than labourer's pay would amount to, so that you get nothing for your skill as a garden-craftsman. As no estimate was made, the owner will doubtless have to pay your bill. Can you not obtain professional advice in the neighbourhood, so as to get the work valued?

BOOKS: Otto Schatz. A small manual, *The Peach and Nectarine*, published by Mr. Upcott Gill, Bazaar Office, 170, Strand, London, W.C., 1s. 7d. by post, would answer your purpose.

CHRYSANTHEMUM: J. C. The bloom of the variety, W. H. LINDA, is a very good one for the date, but Chrysanthemum being superfluous flowers at this season we cannot favour them. Try to extend the season by obtaining good blooms in late January and February, after which month the less we see of large Chrysanthemum blooms the better—until October, at least.

CORRECTION.—Mr. St. Julien Arabin, Belmont Nurseries, Portsmouth, Southampton, desires to inform our readers that Mr. J. Fulford was not appointed manager of the nurseries, as was stated in a recent issue of the *Gardeners' Chronicle*, but to some other office in the same business. The manager of the glass department, recently appointed, is Mr. Tyler, who was with Mr. H. E. May of Edmonton for many years.

CUCUMBER DISFIGURED: A. G. B. The injury remarked is of a mechanical kind, the nature of which we do not know.

FIGS DROPPING FROM POT-TREES: B. C. M. Dryness or excessive wetness of the soil at an early stage of growth causing check to development. As the season advances, the evil usually declines.

FINGER-AND-TOE, OR ASHURY: T. C. R. The disease chlabbing is found in Crucifers only, and is due to a fungus, *Plasmodiophora Brassicæ*. The best method of averting an attack, for it is infectious, is to constantly change the crops, never following a crop of Cabbage, Cauliflower, &c., by one belonging to the same family, and to plant no seedlings which possess swellings on the root. All frames and pits in which the early sowings are raised should be disinfected with burning sulphur; and if the soil can be spread out and similarly disinfected, it will afford more complete security. Leave no remains of diseased plants in the ground, but dig them up, so as to leave nothing behind, and clear forthwith, or bury them the 6 spits deep, as by trenching the land is readily done.

FRUITS AND LEAVES OF STRAWBERRY INJURED: G. M. T. No fungus; but most probably caused by draughts of frosty air impinging on the plants, arresting development, and at last setting up decay.

INSECTS IN PALM SEEDS: G. B. The insects infesting seeds of Chamærops are no doubt minute beetles, but it is impossible to give a name without seeing some of them. The eggs are probably laid when the seeds are soft, and from those seeds with holes in them the perfect insects have no doubt escaped. Suspecting the seeds to have germinating power, there should be no *prima facie* reason why they should not be sown. The insects would not be likely to attack any part of the plant but the seeds, and it would probably be several years before the plants were in a seed-bearing condition, even if allowed to arrive at that stage. As a matter of precaution, we would advise that the seeds be placed with a little naphthaline in a practically airtight box for a few days before sowing. R. McL.

INSECT ON DENDROBIUM: H. K. The beetle damaging *Dendrobium* is *Diaxenus dendrobii*, several times noticed in this Journal. Its origin is supposed to be Brazil or Assam, but all the known examples have been found in Orchard-houses in this country. It is no doubt imported in the plants in the larva or pupa state. Whether it actually breeds here is uncertain. R. McL.

INSECTS: T. W., Blochium. Millepedes: very common indeed, and equally harmless.—*Cucurber*. We do not find any insects likely to have injured your plants, and the roots seem healthy.

MANURE FOR ROSE AND FRUIT TREE STOCKS: W. H. B. In reply to an enquiry on this subject, it may be

stated generally that manures are either forcing or maturing in their effects. Sturdiness of growth can only be secured by the process of maturation and solidity of the plant-tissues; this will be effected by mineral manures of which the ashes of plants are constituted, such as superphosphate of lime, basic slag, bone meal, potash, and the like. Vigour of growth and succulence, on the other hand, are obtained by the application of nitrogenous manures, of which may be mentioned nitrate of soda, sulphate of ammonia, dried blood, guano, &c. To aid the decomposition of the dung which has already been applied, give during the summer the following ingredients per acre:—nitrate of soda 100 lb., superphosphate 300 lb., kainit salt 200 lb. Mix together and apply at two dressings. Or, about 2 ounces of the mixture may be sown per square yard around each tree. Lightly fork or rake in. Ammoniacal guano applied at the rate of from 1½ to 2 cwt. per acre, or 1 ounce per square yard, twice during the growing season will be found of great benefit. The nitrogen and phosphate present in good guano are in such different degrees of solubility that they supply plant food most slowly and evenly through a series of months, the exact time being by other fertilizer. It is therefore particularly adapted for sturdiness combined with a free growth of wood. J. J. Willis, *Hampden*.

MANURES FOR FRUIT TREES: W. H. B. Superphosphate of lime, either animal or mineral, potash; sulphate of ammonia, or nitrate of soda, if the land be poor in nitrogen; bone-meal, kainit, lime. Quantity, separate or alone, from 2 to 3 cwt. per acre, at twice or thrice, with the exception of the last three, which may be used much more freely; soot also is good as manure.

MARKET GARDENING: Alpha. The cold wind-swept stretch of country between Chester and Liverpool is not one which a skilled grower would select in which to grow produce for market; some warm Welch valley, or a spot near the seaboard of South Wales, South Devon, South Cornwall, Sussex, or the indented coast of South Essex, would be preferable even should all the culture be carried on under glass, and still more so if out-of-doors crops be those chiefly depended upon. Round London for a distance easily reached by horse and waggon—say 15 miles—land of good quality is obtainable without much difficulty, but rent is higher and labour dearer than in more remote districts. The Vale of Aylesbury, now well served by railways, could be a good place to start in business as a grower for market. That part of Kent stretching from Maidstone and Rochester towards Swanley, Ottington, and Westerham is a favourite gardening district, as is shown by the great number of orchards, Hop gardens, Strawberry, and Raspberry gardens, &c. existing there.

MUSCAT OF ALEXANDRIA GRAPES, DISEASED, SENT IN TIN BOX, WITH AN UNSIGNED NOTE ACCOMPANYING THEM.—The fruits show signs of "spot," *The sporum leucolor.* There is no known cure, although it might be prevented by the use of the Bordeaux mixture in an attenuated form, or the free use of flowers of sulphur in the spring-water and in evaporating pans, and as a smog, mixed with whitewash on the hot-water pipes. Cut off and burn every affected berry, and avoid suddenly opening the air of the vinery.

MICRO ORGANISMS, &c.: C. D. M., Bombay. It requires a volume to answer your questions. We think you will get what you want in the earlier chapters of *The Natural History of Plants*, by Kerner, Oliver's translation.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—H. J. R., Florence. *Cypripedium* *Gardneri* is a species of *C. pubescens*, and could not be applied to the specimen you send, which is *C. God-froyae*.—*F. R., Wilton.* The name *Maxillaria vanilloides* is applied in gardens to the species of which you send a flower, but we are unable to verify the name; it is near to *Miltonia spectabilis* radians, but the spaces between the lines on the lip in yours is lilac colour in place of white. The three *Odontoglossums* are all varieties of *O. luteo-purpuraceum*, an extremely variable species.—*G. G. Claytonia proflata.* *R. H. B.,* The weed is *Actinella mollissima*. If a lawn be badly infested, nothing less than deep digging and sowing with the best lawn mixture is of any use. Where the weed is not very abundant, dressings of manures to cause the grasses to grow close and thick and smother the plants do good. These

are rotten manure, nitrate of soda, sulphate of ammonia, dried blood, &c.—*Rob. Roy.* *Tilia Europæa*.—*Alta.* *Lanium maculatum*; 2; *Prunus Padus*; 3; *Polyanthum angulare proliferum*; 4; *Cyperus laxus variegatus*; 5; *Ardisia crenulata*.—*J. M.* *Prunus Padus* (Bird Cherry).—*Jane Eyre.* *Ceanothus azureus* var. *Giroire de Versailles*.—*J. M.* *Prunus Padus*.—*G. C. I.* *Limonanthus Douglasii*; 2; *Scilla campanulata*; 3; *Cheiranthus ochroleucus*; 4; *Valeriana officinalis*; 5; *Euphorbia Cyparissias*; 6; *An. Epimedium*; we cannot tell which without the flowers.—*H. C.* *Crotilla Emers.*—*Scapple Plant* *Chromola*, *Ocoidium splachnatum*.—*Bulbous Plant in box with Scyllanthus.* *Trinitia crocata.*

PEACH-BROWING OF THE ROOTS: L. P. The cause of the disfigurement is due to a fungus. Change of ground or sowing on prepared soil placed in holes made with a large dibber, are remedies. Fungus-infested land might be dressed with gas-lime in the autumn.

PEACH LEAVES: J. P. Peach-blisters, caused by a fungus; cut off the leaves and burn forthwith.

PEACHES: A. S. The fruits are mid-wooded, and should be cleared off and burnt. Apply flowers of sulphur to the trees when the leaves are moist. The latter are injured as if by scalding. There is no fungus on them.

PHALANOPSIS: A. G. Soto Fiorotini. The collapse of the tissues shown in the leaf of your *Phalænopsis* is common in *Phalænopsis* under cultivation, and may generally be taken to indicate something unsuitable in their surroundings; or a check in the nutrition of the foliage at some time or other. Sometimes the evil arises from the plants being placed where the direct heat from the hot-water piping reaches them; at others a sudden fall in the temperature may cause it; or defective ventilation. The cause is difficult to name unless one is in a position to see the plants in the situation they were when the mischief happened.

PLUM TREES: H. D. The silver-leaf disease, very common in Rosaceæ. Its origin is mysterious, probably due to a fungus. Cut away freely all diseased portions, and feed the trees well, and they may outgrow it; but generally they die, whether under glass or outside.

SOFT-SOAP TO KILL APHIS: A Reader of the Gardeners' Chronicle. Two to three ounces in a gallon of warm water; half-inch of tobacco-water, or a handful of Quassia Chips soaked in the soap-suds for twenty-four hours would make it more deadly.

STRAWBERRIES BY POST: R. G. Wrap each fruit separately in a soft leaf, say those of the French Bean, Lime-tree, &c., and then place on a bed, half-inch thick, of the softest green moss, in one layer only, with moss between the fruits, in boxes of 8 by 12 by 2½ inches. Several boxes might be tied together if necessary.

TO CLEAN FLOWER-POTS: M. P. If you do not want to wash them, you might make a fire of garden rubbish, and place the pots thereon, and thus destroy all conifers, moss, mould, &c., that may be adhering to them. We should not advise you to use "weed-killer," as it contains arsenic, some of which might impregnate the pottery, and injure the plants placed in the pots. Plan to bury dirty pots in the soil, in coal-ashes, letting them remain for several months, then cleaning them with a dry brush or wisp of straw.

TOBACCO PAPER: Fannygator. The sample sent seems to be all right, but if it be not, we have no means of knowing. Probably the quantity employed was too large for the houses, considering the very tender and easily-injured condition of the foliage and fruits of the Peaches.

TOMATOES: W. de Son. Your fruits are affected with "spot" fungus (*Cladosporium fulvum*), many times figured in these pages. Remove and burn all fruits that are observed to be attacked, and it is important that this be done before the fungus has an opportunity to spread.

THE
Gardeners' Chronicle.

SATURDAY, MAY 29, 1897.

ARBOR-DAY.

NOTWITHSTANDING the luke-warm water which Mr. J. MacDonald poured so plentifully on this project in general, and on the planting of fruit trees in hedge-rows in particular (see p. 292), it is to be hoped that a good deal of extra planting will be done alike in and around towns, and in the country generally, in the sixtieth year of the Queen's reign. Now, too, that trees and hardy plants of all sorts are rendered portable, and therefore suitable for planting at any season, it may be hoped that the act of planting one or more fruit, or other trees, may not be omitted from the functions of the Diamond Jubilee festivities. Already, and very largely through the stimulating example of our Royal House, some event in the lives of many of our greatest men are commemorated by trees, some of which adorn our landscapes. If I remember rightly, it was one of the Dukes of Argyll who said to one of his sons—"Aye, be sticking in a tree, Jock, it will grow while ye sleep;" advice which showed a keen eye for the main chance. Heartily accepted and energetically pursued, it has changed many a barren wild into a profitable forest, and transferred many deficits at the estate bank into substantial balances on the right side; and still there is room enough and to spare for thousands of Arbor-days before the great national work of afforesting our waste lands is completed. Neither should immediate money-profit be the be-all and end-all of our plantings. As you so well said in your leader, we should plant our roads, walks, and footpaths, for shelter, shadow, landmarks, and wind-breaks. Memorial and hedge-rows, shrubs, groups, avenues, home woods, form the essential parts of our richest and most mellowed landscapes. These link the present to the past by the strongest and tenderest ties, make the dead planters live again in their beautiful products, and enrich and ennoble the beauty and verdure of our trees and shrubs, with the sweetness and the light of sentiment.

All this seems so natural and so desirable that it seems difficult to imagine that anyone can be opposed to it. And very possibly Mr. J. MacDonald is not opposed to Arbor-day, nor to fruit-trees in hedges in the abstract. Oh, no! he simply means not there, not now, not so. By all means spread greenery galore in your wide parks, crowd your high-walled gardens with fruits of many colours. But as to planting them against dusty roads, to make thievery of the boys and girls going to school, of the tramps and the travellers, and trespassers and hedge-gappers, or of the open-eyed cattle on the ponice for weak places in the fences, such folly and wickedness cannot be thought of.

Perhaps all this may be put more brightly and pithily in a sentence or so, thus:—Cast not your pearls—that is, your fruit and other trees—

before the stock and the swine, lest they steal your fruit, break your trees, tread down your fences, and, mayhap, turn again and rend you. Will they? I will not, cannot believe it for a moment. All experience—and it is accumulating every day and each hour—is dead against it.

One of the most cheering facts of the century and age is the safety of parks and gardens, as well as of fruit where it is most exposed, and wholly trusted to the general public. School gardens, the growing love of Nature, technical education, lectures, the penny press, the enormous spread and growing popularity and cheapness of horticultural literature, are fulfilling many of the purposes of a popular university in teaching our children their humanities, not the least important of which consists in the knowledge, care, and tender handling of trees, plants, fruit, flowers.

When every home and school child has a fruit tree, bush, or living plant of its own to cultivate, all to and for itself, this last complaint of injury or loss to wayside or hedgerow trees, fruits, and flowers will become less and less, and every free citizen and romping boy and girl will become a protecting policeman to those mute ministers of beauty and plenty that shall early in the twentieth century convert tens of thousands of miles of bald, bare, sunburnt, dusty highways and bye-ways into arbours of verdure, and avenues of Apples, Pears, Cherries, Plums, Walnuts, Chestnuts, Acacias, Mountain Ash, Planes, Damsons, Bullaces, Sloes, Thorns. The want of fruit by the roadside, its absence from hedgerows, its scarcity in so many gardens and allotments, its miserable quality, its dearthness in so many rural districts, are the chief causes of petty thefts and thoughtless injury where either exists. Plant more fruit trees and bushes, trust school and other children more, and let them see and know that they are trusted, and the depredations will cease in proportion till they become so small as not to be worth considering. It is not only quite possible to plant fruit trees near a hedge without injuring the latter, but it would often be easy to form the fences of fruit trees and bushes, such as Damsons and Gooseberries, Bullaces and Sloes.

As a lasting memorial of this Diamond Jubilee year, what more beautiful or gracious souvenir could be suggested than the clothing of several thousands of the miles of our bare walls that disfigure our towns and rural districts? Large numbers of these may be planted with Peaches, Nectarines, Apricots, Apples, Pears, Plums, Cherries, and the shorter ones with Gooseberries, Currants, Raspberries, Roses. Some years since I passed through a village near Oxford, and noted that almost every cottage by the side of the public highway was embowered rather than covered with golden Apricots, which paid the rent of the houses and small gardens, leaving a handsome margin after paying the shoe-bills of the family.

Anyone knowing Cambridgeshire, and East Anglia in general, will be able to recall not a few illustrations of Pears, Cherries, Apples, Apricots, and specially of Gage and other Plums, that have paid the rent of the house as well as clothed them with beauty for years.

Some of the famous backs of the colleges of Cambridge also afford fine examples of Pears and other fruits in clothing high walls with beauty and plenty. There are also some notable trees in the old gardens and orchards of East Anglia as if to prove that the wasted orchards, alas! all too common, did not originate either in the soil nor the climate, but with their tenants, owners, neglecters. Distinguished students of older times, such as Milton, seem to have had their Arbor-days. Hence we have the venerable remains of Milton's Mulberry at Cambridge, and many have enjoyed Addison's long walk at Magdalen College, or the Broad Walk at Oxford. And while not a few of the old giant trees are going or have already gone, young and smaller ones are springing up in various places, one of the most promising of Pears on the Quince, and Apples on the Paradise, forming

the fine new gardens occupying the space between the Botanic Gardens and the Great Eastern and other railway stations at Cambridge.

Not a few towns, notably Perth, used to be famous for its Jargonelle Pear trees within the city, and it is to be hoped that its growing stock-market and expanding railway traffic have neither lessened their numbers nor lowered their quality.

Nor need the fruit from hedge-rows be so inferior or worthless as Mr. MacDonald assumes, as to make it as hardly worth growing or gathering. A little extra skill and forethought might easily render hedge-rows some of the most perfect sites possible for fruit-growing.

Sufficient soil may readily be had or provided; excess of water is impossible on the crown of a ditch-bank, or the top of a hedge-row; light, air, dew, rain, abound.

But it would be a waste of space to argue the point *de novo*. After all, fruit and other trees in hedges are not so rare as to be unseen and unknown, or seen only as mere scarecrow bogies, perched or crowded up as warnings to fence-breakers, stock-loosers, and producers of rubbishy fruit. All this is begging the entire question to frighten Arbor-day planters from our waste places, road-sides, hedgerows, bare walls, houses, railway embankments, allotments, and small gardens.

But why should they pause in their great and patriotic work of planting? Your correspondent seems almost to give up his whole case against fruit-tree planting in hedge-rows when he chronicles the effects of a hungry Elm-tree on a crop of Potatoes as his strongest charge against it! Neither I, nor you, nor anyone else want to spoil a good hedge for the satisfaction of growing inferior fruit.

Quite the contrary, and there is no reason why the waste walls, treeless hedge-rows, should not become coigns of vantage for the higher culture and more telling display of superior fruits. Such is also the teaching of Mr. MacDonald, only a few sentences before his summary of evils and mischiefs of hedge-row and roadside planting. The following sentence is so valuable that I must quote it entire.

"Where the hedge-rows are under the supervision of the County Council, such plantations (that is, of fruit-trees in them) would be a great advantage as examples for their instructor to demonstrate upon, as the position they occupy would be such, that even those who ran, or rode either, could read exactly." And to read to any good purpose of pleasure or profit the trees and the crops must prosper. Permit me to conclude with the closing sentence from your leader on p. 236, for the special management of Arbor-day road-side and hedge-row planters. "A man who plants a tree properly is a public benefactor; if he can combine his beneficence with a village festival, and so lighten the dulness of village life, while at the same time evoking a spirit of patriotism, he will be a three-fold benefactor." *D. T. Fish.*

NEW OR NOTEWORTHY PLANTS.

TREVORIA CHLORIS, *n. gen. et spec.**

This is the second of a number of new genera of Orchids which I have discovered during the twenty-one years of my travels in the Andes. Both *Trevoria* and my *Gorgoglossum* are old acquaintances of mine;

* *Trevoria*, *n. gen.*—Sepala crassiniscula, libera, patentia sequilongis, concava, columna basi oblique inserta, lateralibus ovatis maximis. Petala crassa, patentia, tertia sepalis concavis angustiora. Labellum carnosum, concavum, erectum, cum basi columnae immobilitate articulationis, antice trilobum; lobis laterales erecti dolabriformes, columnam laxo semianplectentes; lobus medianus continuus linearis hastatus, acuminatus, porrectus; discus angustatus, acute unguiculatus, pectus in ligula carnosus, libera, columnae equilonga et parallelis protractis. Columna longissima, teres, spica clavata v. abrupte truncata, alba, in imo basi geniculata, apud Cinnamodium planum v. leviter convexum, reclinatam, exaristatam(?). Restellum bidentatum, membranaceum. Stigma fovea sub rotunda transversa excavata. Anthera terminalis opercularis, membranacea, 1-locularis. Pollinia 2, vermicis, oblique pyriformia, pectice sulcata, longipendiculata, debicantibus albis. Caudiculi ligulati s'g.

but owing to their great rarity, and their growth in habitats very difficult to reach, insufficient floral material have made it hitherto impossible to publish them (see fig. 128).

Gorgoglossum Reichenbachianum, Ledeburn (M.S., 1879), was met with in December, 1879, in one single specimen on the Western Andes of Ecuador, at an elevation of 300 to 600 metres above sea-level. The single specimen was duly given to the late Professor Reichenbach; but the flowers, having lost their pollinia, he did not venture to describe the plant, and it wandered with some 3000 other numbers of the herbaria for twenty-five years to the grave at Vienna. Some eleven years later, when I knew already the fate of my unique *Gorgoglossum*, I undertook an especial journey to the locality in order to secure a few plants for cultivation in one of my estates in the Cauca. Only five plants were found, of which to-day one exists in my possession, and another in that of Sir Trevor Lawrence, the rest having been lost on the sea-voyage.

set seed-vessels, but no flowers. The plants I tried to take to the Cauca for cultivation, but alas! they were stolen from me by some rascal at Esmeraldas during my absence from the steamer, together with a number of other botanical treasures. Nothing more was seen or heard of this plant, which, by-the-by, looked quite novel and interesting until last year, when during an exploration of a certain portion of the Western Andes of Colombia, with a view of projecting a map on behalf of the Cauca Government, a few plants of this species of Orchid were observed. The species found in Colombia is, however, quite distinct from that of Ecuador. The latter grows at an elevation of 500 metres above the sea, and produces flower-spikes of from twenty to thirty flowers, the size and character being as yet unknown, while the Colombian one inhabits a region from 1,500 to 1,700 metres above the sea (as far as observed), and bears racemes of only three to five—commonly, only three flowers.

As a genus, *Trevoria* is very characteristic and

I have named this genus of Orchidaceæ in honour and commemoration of Sir Trevor Lawrence, one of the most enthusiastic orchidists that ever lived. *Trevoria* has to answer our purpose; *Lawrencea* and *Lawrenella* being already in existence in Composite and Malvaceæ respectively. May Sir Trevor's love of Orchids *perdue sempervivax* as *Chloris* the goddess of flowers. *Popayan*, February, 1897. *P. C. Lehmann*.

HOME CORRESPONDENCE.

CAPTURE PLANTS FOR INSECT PESTS.—As one of the earliest cultivators to employ Mustard-seed plants and dross as decoys for dipterog and destroying wireworm, I was much interested in your note of last week in *Gardeners' Chronicle*, p. 305. It will prove glad news to many that wireworms will forsake Carrots and Parsley to feed on Lettuces. It is less surprising that the mole-cricket, where it proves

FIG. 118.—*CALADIUM ALEANENSE*: BRONZY-GREEN, CRIMSON CENTRE.

CALADIUM SPECIOSUM: VIVID GREEN, WITH BROAD CREAMY-WHITE VEINS.

(Exhibited at the Temple Show by Messrs. F. Sander & Co. See Report, p. 553.)

My first acquaintance with *Trevoria* occurred in 1857. Only three specimens were seen, bearing thin, drooping spikes, about 40 cm. long, of thickly-

modica: glandula parva clipeoides. Capsula fusiformis, leviter acuta, delicata.

Herbæ epiphytica: Americæ tropicæ, pseudobulbis elongato pyriformibus, non compressis, 1-foliatis. Folia ampla, subcoriacea, plicato-venosa, in petiolum contracta. Scapi ad basin pseudobulborum inversi simpliciter. Racemi laxè pauciflori, floribus maximis, carnosis, pedicellatis. *F. C. Lehmann*.

Trevoria Chloris, n. sp.—Laxe caespitosa. Pseudo-bulbi longe pyriformes. Folia oblonga lanceolata, acuminata, longe petiolata, plicato-venosa, usque 0.40 m. longa, 0.10 m. lata. Spica pendula pauciflora, vulgo 3-flora. Bractee triangulo cuspidatis, cucullatis. Sepalum dorsale oblongo-lanceolatum, acuminatum, revolutum, 0.35 m. long., 0.15 m. lat. Sepala lateralia ovata, oblique acuminata, 0.05 m. long., 0.03 m. lat. Petala ligulato-falcata, torta, cuspidata, 0.06 m. long., 0.008 m. lat. Labellum supra descriptum; hypochilium 0.02 m. long., epichilium ligulatum 0.04 m. long., 0.004 m. lat. Flores carnosæ, viridæ, discus albus.

Hab. Colombia: crescit ad arbores in silvis densis, humidis, ad declivitates occidentales. Andium occidentalium civitatis Popayan alt. s.m. 1500—1700 m. mense Septembri—Ocotubri threns *Hedb.*, No. 10,625. Ledeb. *f. Plant. M.S.*, t. 1077. Popayan mense Febr. 1897. *F. C. Lehmann*.

distinct. Its nearest neighbours are *Coryanthes*, *Schlimia*, *Stanhopea*, and *Gorgoglossum*, but it is distinguishable at first sight from either of them. *Trevoria chloris* produces large fleshy wholly green flowers, placed on the drooping spike in the manner of the buckets on a dredger-chain. The narrow disc of the lip and the thick coriaceous process at its base are the only different coloured organs in the flower; they are pure white. Both from a morphological, as also from a physiological point of view this genus is very novel and interesting. The position of the column and lip, standing straight upright in an ureolate manner, the thick fleshy process at the base of the lip, being of exactly the same length as the column, and standing parallel and closely adpressed to that organ, the peculiar shape and insertion of the stigma and several other items are wholly novel, and the arrangement of them to each other may set at naught some of the pet views of modern hypercritical speculators with respect to the aid of insects in the fertilisation of Orchids, or give rise to quite new conceptions.

destructive to indoor or ridge Cucumbers, should be allured from the Cucumber roots through a bait of mealy Potatoes. A serious question arises in connection with most capture plants; viz., the future effects of the special feeding on the reduction or increase of the pest. It seems quite conceivable that a liberal ration of such capture-plants as Mustard, Lettuces, Potatoes, Carrots, succeeded in not simply diverting the pests from one crop to another, but also in destroying pests, or forcing them to shift their quarters. In a word, more practical evidence seems wanted to prove that the Lettuces and Potatoes, not only saved the Carrots, Cucumbers, Parsley, through feeding the pests on pastures new and sweeter, but that the capture-plants weakened and decimated the pests. In our earlier attempt with capture-plants, the main object was destruction rather than diversion. The theory and practice was and is on the old lines, to begin with feasting and end by totally destroying the wireworm. Few of the worms that fed on Clover that was Mustard lived to feast another day. Cultivators are grateful for temporary relief from these and other insect-pests. But a permanent deliverance would prove a far

greater boon. Wireworms perished through their eating of Mustard to excess, and its consequences. Have any equally destructive effects been noted from over-feeding on Potatoes or Lettuces? Or has any one found feasts of Lettuces to lull wireworms into inertia for good? Anyhow, Lettuces seeds are plentiful enough, the plants grow quickly, and it is something gained to be assured the wireworms prefer Lettuce to Carrots and Parsley, and so the two last crops are saved through the temporary diversion, if not the destruction, of the wireworms. *D. T. F.*

AQUILEGIAS.—Dr. Williamson, in his interesting paper on these hardy plants, winds up by pronouncing for *A. chrysantha*, as the very best and strongest. That is so in relation to pure species, though next to it I have found *A. corulea* to be robust and beautiful. But following upon the crosses made by Mr. Jas. Douglas some years since, and which gave to us such charming hybrids, I some years ago also crossed *A. corulea* with *A. chrysantha*, and *vice versa*, getting as the product practically identical results in plants that were stronger, more floriferous, and consequently much more effectual than either parent. *A. corulea* bloomed earliest, the hybrids were intermediate, the

FIG. 119.—FRUITS OF DRACENA GODSEFFIANA.

issue of this journal, an article appeared over the signature of Mr. Macdonald, decanting on the disadvantage of fruit trees in hedgerows. In choosing trees for hedgerows, it is essential to consider what they may be forty or fifty years hence as regards their size, form, and money value, not omitting their value as picture trees. Of those species which are suitable for growing in hedgerows, there are the common Horse-Chestnut, common Ash, English Oak, Sycamore, white and purple Beech. Other varieties may be added, but those mentioned are valuable for their timber, and if judiciously planted and mixed, would give a pleasing effect to the eye of the traveller, and greatly enhance the beauty of the landscape. [We fear that the timber merchant would give but little money for hedgerow trees. Ed.] Mr. John Morrison, Coney Park Nurseries, Stirling, in his prize essay on "Hedgerow Trees," written for the Highland and Agricultural Society of Scotland, prefers trees planted 2 feet in front of the hedge, rather than in the line of hedge itself, and for the reason that they are apt to make gaps and spoil the usefulness of the fence; and by planting in the manner indicated by him this objection is obviated, the fence being preserved intact. Trees standing singly are more

FIG. 120.—DRACENA GODSEFFIANA: LEAVES GREEN, SPOTTED WITH YELLOW; FRUITS ORANGE-RED.

(Exhibited at the Temple Show by Messrs. F. Sander & Co. See Report, p. 323.)

straw-yellow *A. chrysantha* coming last. If the growth of the first named was but moderate, that of the latter was tall and rather loose. Here, again, the hybrids were intermediate, and combining the large flowers of both in diverse hues and shades, produced them in greater abundance and more compact form. A row of the hybrids beside rows of the parents out-distanced them in effect and in beauty materially. Many of the Messrs. Veitch & Sons' lovely hybrids no doubt have both Skinneri and californica blood in them, as well as that of the two species I have named. Only ignorance of the Columbo in all its pristine as well as hybrid beauty keeps

it out of our gardens. Yet from a few cheap seed packets, the seed being sown at once, may be obtained next year scores of plants, giving the most quaint, picturesque, and beautiful flowers that hardy plants produce. Old plants become rather exhausting of soil, and it is a good plan to raise some seedlings every year, and destroy those that are some four years old, planting each season in fresh soil. *A. D.*

HEDGEROW TREES.—The subject of trees in hedgerows is an important one, which it might be of advantage to many readers of the *Gardener's Chronicle* to discuss at some length. In a recent

exposed to severe winds than in a plantation, and care should be taken to supply them, as far as possible, with the power of resisting the storm. This can be done to a great extent by pruning, which leaves the least area of crown to be acted upon by the wind, whilst giving the tree the power of strengthening its roots. Any straggling branches should be shortened, so as to afford the desirable balance which a tree ought to have. The rule would be, allow the top of the crown scope, but to shorten the side branches when and where necessary. By so doing, the result will be a fine, stubby, firmly-standing tree, possessing great power of resistance to

the wind. Cut off the lower branches from time to time, until they are clear of the top of the hedge, and have a clean stem of from 10 to 12 feet in height, or, at the least, considerably higher than the hedge, which will allow direct sunshine to reach the hedge plants. *A. J. H.*

BUD VARIATION IN PYRUS (CYDONIA) JAPONICA.—A deep scarlet shrub of this species, which has been growing in the garden here for a number of years, produced last year a clump of bloom of a pale pink colour. I marked the twig, and find this spring five clusters of blossom of the same tint. The whole branch bearing these flowers consist of about five shoots, and stands out conspicuously from the rest

to the cultivator or raiser of new varieties. Ed.] But the process as presented by Mr. Galton seems to be singularly difficult to conduct. In all our work in relation to flower development the practice has been invariably to select the best form for seed-production or breeding, and thus go on from year to year in higher development. That being so, could not all that Mr. Galton desires be obtained by proceeding on the reverse process, literally one of backwardation, by selecting not the best, but the worst product of every fresh sowing of seed, and thus see how soon or how long it may be possible to arrive at the original starting-point. Why not try the finest strain we have now of the Cincarra, or Cycloneu, or Chinese Primrose, or even the tuberous

ley's Seedling. The samples sent were good samples of the respective varieties, the Prince Albert being abnormally destitute of colour. The Apples were cooked in their rinds in a quick oven simultaneously, the Prince Albert having about ten minutes more to cook the fruit to a similar good edible condition. The difference in favour of the superior quality of Bramley's Seedling was strongly marked. I have no hesitation, however, in adding that both Apples are proving useful and popular in various places, and some of the samples sent are likely to keep till June, though the late Dr. Hogg gives January as the season for Bramley's Seedling, and October to March as the season for Lane's Prince Albert. As already stated, both are in fresh sound condition on May 12. Perhaps

FIG. 121.—*CYPRIPEDIUM CHLOLEARE*: STANDARD WHITE, WITH GREEN VEINS; PETALS PURPLISH-SPOTTED; LIP DULL PURPLE, DOWNY.

(Exhibited at the Temple Show by Baron Schroder. See Report, p. 353.)

of the tree, with its deep red blossoms. The petals come near in colour to those of the Apple, having their edges fringed with white. Now, as far as I am aware, the scarlet is the original colour, and the white and pink-flowered shrubs we see also in gardens are varieties. Perhaps some of the readers of the *Gardeners' Chronicle* will be able to say whether these latter have arisen through bud variation, somewhat after the fashion of the above case, or through variation in seedlings. *J. Parkin, Blithwaite, Chorlton.*

RETROGRADE SELECTION.—Whilst to an ordinary gardener what Mr. F. Galton proposes to do in relation to tracing back the development of a garden plant of some annual description to its origin seems sheer waste of effort, no doubt it will present interesting experiment to the student in plant evolution [and by no means without value

Begonia? because all these have been evolved out of very inferior origins. *D.* [No plant of hybrid origin is available. *ED.*]

BRAMLEY'S SEEDLING AND LANE'S PRINCE ALBERT APPLES.—A good deal has already been written about the relative and comparative merits of these two Apples. Through the kindness of Mr. Merryweather of the Southwell Nurseries, I have had the opportunity of tasting or re-tasting both to-day, May 12. A correspondent on May 1 assured us that Bramley's Seedling was a fine cooker, but very sour. We did not find it the latter at all; but the same correspondent wrote that Bramley's Seedling did not keep till after Christmas, and yet here we have just eaten it in splendid condition on May 12. Neither can I endorse the opinions of other correspondents, that the quality of Prince Albert is equal or superior to Bram-

it may prove useful to give Dr. Hogg's estimate of these two Apples in his latest edition of the *Fruit Manual*. "Bramley's Seedling: fruit large, 3½ inches wide and 2½ inches high, handsome, and at first sight resembling a Blenheim Pippin. It is oblate, even in its outline, and with fine, rather distinct knobs at the crown; skin very much covered with a tinge of pale red, which is much striped with darker red, and where shaded the ground colour is yellow; eye rather open, with erect segments, which are reflexed at the tips, and set in a wide, round, saucer-like basin; stamens median, tube funnel-shaped; stalk very short, sometimes a mere knot; flesh with a yellowish tinge, tender, and with a fine brisk acidity; cells round, axils open. A very valuable cooking Apple in use up till January;" and Dr. Hogg adds, "it is a Nottinghamshire Apple, and was sent me by Messrs. Merryweather & Son, of Southwell."

One is amazed at the truth of the description of Lane's Prince Albert: "Fruit large and handsome, $\frac{3}{4}$ inches wide and $\frac{3}{4}$ inches high; short, conical or ovate, even and regular in its outline, with broad obtuse ribs round the crown; skin smooth and shining, fine grass-green at first, but changing to clear pale yellow as it ripens; where exposed to the sun it is pale red marked with broken streaks of bright crimson; eye rather small, close, with erect pointed segments which are relaxed at the points, set in a deep saucer-like basin; stamens basal, tube funnel-shaped; flesh tender, juicy, briskly and agreeably flavoured; cell elliptical, axially, cord-like." Dr. Hogg adds, a very excellent culinary Apple for October to March. It was raised by Messrs. Lane & Son of Berkhamsted. The tree is a marvellous bearer, and rarely fails to

other crops, contiguous to express and other railways, one can easily read between the lines his anxiety to console artists, landscape gardeners, and lovers of nature, who may have failed to establish bracken. Virtually, and in his most sprightly manner, he proceeds to point out how very much they may have gained in safety, and in profit, through their failure to brackenize their woods and landscapes. And it would be difficult to place a more vivid anti-bracken object-lesson in your pages than that of the late, deeply lamented Mr. Findlay, of the Manchester Botanic, struggling to the waist or neck in a veritable maize or tangled sea of bracken; the vision will probably suffice to give pause to the most bracken-stricken enthusiast. And yet possibly few landscape gardeners would regret indiscriminate raids on bracken more than Mr. Simpson, surrounded, almost

the roots early in April, will kill the major part of them. But it cannot be needful to wage a war of decimation, to say nothing of extermination, against bracken. Mr. Simpson's spark-guards on funnels would prevent the firing of bracken and other crops, timber-yards, &c. The beating back of such crops from the sides of the line would also do much in the same direction. The early cutting or harvesting of bracken would reduce the risk of fire to nil, for bracken is by no means inflammable till dead ripe. Cutting the crop before this stage of perfect maturity would also improve its fibre for paper-making, and possibly for other trade purposes, as well as greatly improve bracken for the bedding of live-stock, and the protection of fruit-blossoms, Roses, &c. In some of our best nurseries nothing else but sprays of bracken have been used for the protection of Tea and other

FIG. 122.—MACARIA PANDANIFOLIA (CYPERACEÆ).

(Exhibited at the Temple Show by Messrs. F. Sander & Co. See Report, p. 353.)

produce a crop. Singularly enough Dr. Hogg fails to name the stalk, which is long and slender, and turned to one side. D. T. F.

HOW TO DISESTABLISH BRACKEN.—I have seldom enjoyed an article more than that of Mr. Simpson, of Wortley, on the above in a recent number of the *Gard. Chron.* There was a freshness about it born of the woods of bracken so vividly described. No doubt, under such fiery conditions as environ the woods of Wortley, dried bracken may at times prove a huge tinder-box to set the woods and forests in a blaze; and hence Mr. Simpson's vigorous protest against fringing our railways, canopied with streaming comets of red-hot sparks, with powder-dry bracken in autumn time, unless taking the precautions to confine the fire-showers to the barren track of the line, or beating back or cutting down the bracken to a safe distance. While doubtless Mr. Simpson's main object in writing was to ensure the greater safety of plantations, ripe corn, hay, and

honeycombed, with railways, as many of the plantations and pleasure-grounds in the North are, it was doubtless his duty to call out fire at every sign of wider risk or of fresh danger. Neither will anyone who knows Mr. Simpson, accuse him of exaggerated views of the vicious of the bracken, its tinder-like inflammability, or the speed and energy of its combustion. The only match, or rather master, in speed and intensity of heat that I have met with was found in a mixture of bracken and pampas-grass. A match was set to a group on a hard dry March day, and in an instant the whole was in a fierce blaze, and a very expert movement was needed to save clothes and a severe scorching. The bone dry pampas went off more like an explosion than an ordinary fire. Dry bracken burns almost as swiftly, but nothing like so fiercely. I fear there is no easy way of getting rid of bracken. In woods, the roots of the trees prevent steam-ploughs, smashers, &c., working with much effect or freedom. On poor Heath land in the open, such implements, or forking, or digging-out

tender Roses for years; the lightness, mobility, toughness, and durability render it the most effective wall-screen in fruit blooming time, also the safest shelter to all semi-tender Roses. Bracken is also a capital protection to early Potatoes, Peas, Beans, Lettuces, Parsley, &c. Unless the paper-mills will take all Mr. Simpson's early harvested and tough fibred bracken, possibly he might be able to put a few hundred tons on the rail at fairly remunerative prices for protective and bedding purposes. If harvested sufficiently early, there would be no fear of the spores converting our fields and gardens into wildernesses of bracken. Room enough and to spare may mostly be found on all estates for fine groups and tangles of bracken without injury to young woods. Few could see masses or crowded plantations of this finest of all our native Ferns, not omitting the *Osunda regalis*—I mean the common bracken, *Pteris aquilina* in many varieties, with its brownish lush-green fronds, tender and crisp; about 3 inches high, or its stout, wide, creeping rhizomes, without

recalling some old-world superstitions or facts of these juicy leaflets and stems being esteemed as good for food, and that the glutinous rhizome of the closely allied species, *T. saccata*, is still eaten by the aborigines, and known as the edible Fern of Tasmania to-day. When some new chef shows us how to cook and eat our bracken shoots and roots in safety, and our manufacturers convert their fibre into good paper, possibly the Wortley bracken, now condemned as dangerous and useless, will rank as a profitable crop, as well as stand out more prominently than ever as a thing of beauty and a joy for ever. Early in the twentieth century it is hoped Mr. Simpson will be able to chronicle the effects of the renaissance of our old excellent Fern on the popularity and prices of our native Asparagus. *D. T. F.*

PROGRESS OF THE CYCLAMEN.—The editor has done me the honour to reprint in his pages the paper read by me before the Royal Society. No doubt, to save time, he has supplied, for the most part, his own illustrations. They will serve, though I think those given in the original paper, which were carefully drawn, to show the dimensional changes in a more convincing manner. But I must disclaim all responsibility for fig. 114, which is entitled the "Crested Cyclamen," and cited on p. 331 as representing the "Bush Hill Pioneer." It does not do so, but was avowedly the product of the artist's fancy, and a conjecture as to what might be, not anything that so far actually exists. *W. T. Thidston-Dyer.* [We regret that by an inadvertence the wrong block was used; the correct one will be found in our number for January 30, fig. 18a, p. 76. Ed.]

KEW GARDENS.—In taking a quiet look over the externals of Kew Gardens the other day, for I did not visit the houses, I endeavoured to enjoy them very much as an absolutely unprofessional person might be expected to do who had an innate love of the beautiful. Possibly it is difficult to do so, as the professional Adam will crop up in the breast of the best of us, and the tendency to criticise will assert itself; yet, in spite of this irrepressibility, I could but enjoy the gardens most truly. So beautiful and so well kept, for here again the gardener will always be true, were they that I fear would leave critics to rest, and thought only of the delightful surroundings. Really, looked at from the purely uncoloured visitors' point of view, it seems almost impossible to find anywhere near town or in the country such a delightful place as Kew is. Such noble trees, such beautiful flowering ones, such remarkable collections and combinations of shrubs, such lovely glades, such charming expanses of verdure, such music of birds, such soft sweet air, and all so near to London, with its noise, its smoke, and its hurry and drive of life. Poets and writers may cherish the paradise of rural scenery, and much of it is indeed beautiful, but millions of British people visiting Kew on a warm sunny May day, would aver that the gardens were the loveliest they had ever seen. All this is after all more of garden praise than of scientific work, but the present management have in a remarkable degree shown how science in the form of botany and horticulture as exemplified in the creation of that which is beautiful in gardening, can go hand in hand. After all, it is only those who see Kew that can fully realise what the gardens really are. *A. D.*

EEL-WORMS IN PASTURES.—If "A Novice" will kindly refer to the enquiry of "M. F." in the *Gardener's Chronicle* of May 1, p. 296, he will see that the eel-worm mentioned is *Tylenchus devastatrix*, which is exceedingly mischievous, and spreads with great rapidity. I had doubts as to the pest being *T. devastatrix*, so recommended a manurial mixture which I knew would greatly benefit the pasture, and doubtless assist the plants in overcoming the pest if it did exist. "A Novice" will see that the reply states—the treatment will not entirely destroy the pest. In fact, if "A Novice" has had any experience with *T. devastatrix*, he will know full well that it is extremely difficult to eradicate when once established; and I repeat, that turf known to contain this pest should not be used for potting purposes. Miss Ormerod says:—"It should be borne in mind that eel-worms can be conveyed in infested earth. They are thus conveyed on wheels of carts, in earth clung to farm implements, and to garden tools, and even on the boots of farm-labourers; and from their power of progressing a small being makes much trouble." Doubtless a chemical agent might be found which would destroy *Tylenchus*, but this would mean destruction of the growing plants also. When dealing with crops or delicate plants, it is not

easy to destroy an established pest without injury to plant-life also; therefore I say try remedies and watch the results. So far as I know there is no *Tylenchus devastatrix* in this neighbourhood at the present moment, and we do not wish to impart any; consequently cannot carry out the experiment "A Novice" suggests. If gardeners when they are troubled with injurious insects or fungoid diseases would try certain remedies and watch the results, reporting success or failure, in this or in similar journals, they would be doing good work. I shall be interested to learn the remedies which "A Novice" says have been found successful in combating with *Tylenchus devastatrix*, and I am sure Miss Ormerod would also. This talented lady and Dr. Ritzema Bos, director of the Phyto-Pathological Laboratory at Amstcrdam, a great authority on this kind of infestation, have been working for several years past on this and similar subjects. *J. J. Willis, Harpenden.*

LILIUM THOMSONIANUM.—In alluding to *Lilium Thomsonianum*, Royle in his *Illustrations of the Botany*, &c. of the *Himalayan Mountains*, vol. 1, p. 388, 1839, says: "I have named this species in honour of my friend, Dr. A. T. Thomson, Professor of Materia Medica in University College, author of lectures on botany, 1822." *J. E. T. A.*

A FINE DENDROBIUM FALCONERI.—I send for your inspection a photograph of a *Dendrobium Falconeri*, grown at The Mount, Castlehead, Paisley, by Mr. Matthew Strong, the gardener at that place. It possesses eighty-two flowers. Towards the end of the month of September it is taken into a cool greenhouse and rested there until it shows its flower-buds—generally about the beginning of April, when it is taken into the intermediate-house. In most *Orchid Manuals* it is recommended to be grown in strong heat; but Mr. Strong has grown this in an intermediate-house, which he finds the most suitable for the plant. *Robert Macfee.* [The photograph shows a pretty plant, but it is, unfortunately, unsuitable for reproduction. Ed.]

PREMATURELY-DUG BULBS.—Your correspondent, Mr. Earley, p. 341, does well to call attention to the manner in which that clever gardener, Mr. Jordan, the superintendent of the Regent's Park, prepares and stores his bulbs for spring bedding. I once had the pleasure of looking round" with Mr. Jordan, and the only thing I can compare his store to was the old florists' Tulip stores, when single bulbs of some kinds were worth £50 a-piece, such was the order and care, and their skins shone like the finest Dutch bulbs. Perhaps Mr. Jordan would himself describe his method of drying and ripening the bulbs? *R. M., Newbury.*

THE WEEK'S WORK.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorking.

Water for Orchids.—Without any doubt the health of Orchids, when under cultivation, depends upon the quality of the water afforded, the time, and the manner of its application. It is now pretty well known that rain-water is the best for these, as for every other species of plants, and as much as possible of that which falls on the houses, sheds, &c. should be led to underground tanks and house-cisterns, other means being taken to supplement the water supply in periods of drought, adding some occasionally to the rain-water, and thus eking out the quantity. A sufficient quantity of pure rain-water should be set aside for syringing purposes, other kinds of water leaving a deposit of some sort on the pseudo bulbs and leaves, which stops up the stomata, and is unsightly. River-water is generally preferable to that from underground sources, but whenever obtained the latter should be exposed to the air in open cisterns for some time before it is used. A tank in one or two of the warmest houses should be provided with a hot-water pipe of small dimensions laid round the tank, and as near to the bottom as possible, with valves on the outside to regulate it. This is not recommended with the object of increasing the humidity of the air, evaporation by this means being productive of the dreaded "spot"; moreover, evaporation from this source is dangerous to the health of the plants generally when the temperature of the houses is much below the proper standard. At this season, and during the summer months, the temperature of the water for watering the plants in the East Indian-house should be about 65°, and in the autumn it should be reduced to about 63°, and in very cold weather to 60°.

For the Cattleya, and other intermediate-house plants, the temperature of the water should be reduced several degrees below these figures, and for *Oncotlossus*, *Macleodias*, *Oncidium*, and other cool-house *Orchids*, it should be as warm as the night temperature of the house. Affording water, syringing, damping, &c., will take up much of the cultivator's time during the next three months.

THE FLOWER GARDEN.

By CHARLES HERRIS, Gardener, Drogheda, Maidenhead.

Bedding Out.—Spring bedding plants will now have to be lifted to make room for those about to be planted. If the drying winds and fine weather continue, extra care will be required in transplanting, in order to preserve the stock for another season. *Primrose* and *Polyanthus* may be divided, and afterwards planted at about 6 inches apart each way on a shady border. Here they will develop into good clumps ready for transplantation in the autumn of the following year. *Pansies* and *Violas* should be laid in temporarily in drills, and these and all other subjects must be well supplied with water when necessary.

Tulips and *Narcissus*, if they are to be planted again, must be lifted with all the soil that bangs to them, and laid in trenches in the reserve garden, and if allowed to ripen off naturally, the bulbs will not seriously suffer; and as soon as the tops wither and can be bent without snapping, they should again be lifted and spread out to dry in a cool shed preparatory to cleaning and storing.

Narcissus poeticus and *Jonquils* may be lifted, and after the beds have been dug and manured, the bulbs may be planted back in patches of five or six, at 9 inches apart, selecting the largest bulbs. The to s, if twisted into a knot, will not be in the way, and providing the beds are to be planted with *Pelargoniums* or similar plants, these are easily planted between, and when cleared off in the autumn the bulbs have made a good start. Several beds are annually treated in this way here, and the bulbs flower satisfactorily.

Wallflowers.—To produce good stocky plants for next season's flowering, the present is a good time to sow the seeds. In light soils, a north border forms a suitable position for the seed-bed, and in any case a cool and partially-shaded site is desirable. After the soil has been raked down and the surface made fine, draw shallow drills 9 inches asunder, and in these sow the seeds thinly. The seedlings may be thinned and left to grow large, or they may be transplanted to about 8 inches apart, as soon as they have formed three or four leaves. If it be a dry time, afford water to the drills with a fine-rosed can on a short time before sowing the seeds. *Veitch's Blood Red* and *Belvoir Castle Yellow* are good strains of dark and yellow *Wallflowers*. *Fairy Queen* or *Primrose Dame* is a pleasing *Trineus* colour, but it lacks fragrance. *Sturton's Earliest of All's* *Wallflowers* are early-flowering varieties, and a fair proportion of double flowers may be obtained from a selected strain of the *Double German variety*.

Canterbury Bells.—Seeds may be sown now, similarly to *Wallflowers*. *Campanula pyramidalis* and *C. p. alba*, and the perennial varieties, may also be grown in this way out of doors.

THE KITCHEN GARDEN.

By W. FORT, Gardener, Highgate Castle, Newbury.

Spinach.—If a regular supply of fine *Spinach* is demanded by the family, a sowing should be made once a fortnight, the plant bolting quickly, even when thinned early. If a mild or disused hotbed be available, seeds of the *New Zealand Spinach* may be sown, and as a few plants of this soon covers a good space, and will yield many pickings of thick succulent leaves, a few plants will usually suffice for the needs of a large establishment. *Orach*, or *Mountain Spinach*, may also easily be grown, and should be given a trial where ordinary *Spinach* fails, as it sometimes will, on dry hot soils.

Late Broccoli.—The *Late Broccoli* are now coming in apace, and notes should be taken of new varieties to serve as a guide in the future. That well-known old variety *Cattley's Eclipse*, is still one of the most trustworthy, and *Sutton's Late Queen*, and *Veitch's Model*, are also very superior *Broccoli* at this season. If seeds of these varieties have not yet been sown, no time should be lost, strong and well-matured plants being required to withstand the inclemency of an ordinary winter, and all crowding in the seed-bed, or afterwards, should be avoided.

Tomatos.—The out-of-doors plants require a rich but firm soil, and a sunny position either on or in front of a wall after planting. Afford water freely till the roots have seized upon the soil; apply a slight staway mulch, and stake and tie the stems securely. If a stimulus to growth be required when the plants are in bearing, let it be in liquid form. Plants growing in the open air are the best when kept to one stem, all laterals being removed as fast as they appear. Tomato plants standing in the open should be stopped at 3 feet from the ground; and, given a warm summer and well-prepared plants, heavy crops of fruit are obtained.

FRUITS UNDER GLASS.

By F. HARRIS, Gardener, Eastnor Castle, Leicestershire.

The Early Vinery.—The Grapes in this vinery, if the Vines were started in December, should now be in process of colouring, a stage at which the Vines should be freely afforded air to ensure good colour,

Succession Vinerias.—The Vines in these vinerias, the thinning being finished, will require much attention in regard to the stopping of the laterals, keeping the borders, if inside, in a proper condition as regards water, and damping of the paths and surfaces generally. Aged Vines carrying a heavy crop of bunches, will be greatly benefited by liquid-manure mixed with hot-water, so as to make it tepid, copiously afforded to the borders when the latter are in need of moisture. Careful ventilation is very necessary at this season of sudden bursts of sunshine and cold winds, or evils of various sorts will be met with. Afford air in small amount as soon as the warmth begins to rise in the morning, gradually increasing it till the maximum is reached for the day. By affording air at this season as much as possible by the upper ventilators or lights, the impinging of cold draughts on leaves and bunches will be avoided. Never open ventilators all at once to a great extent, this being a fruitful cause of mildew, rust, &c.

to shelter itself in cracks and crannies in the bark, woodwork, courses of the brickwork, to the soil beneath the hot-water pipes, consequently the gardener will do well to keep as much as possible all such places well moistened daily either with clean water or manure-water, and sulphur be intimately mixed with such swill-water, much good will be done. ED.]

PLANTS UNDER GLASS.

By G. H. MARCOCK, Gardener, Luton Hoop Park, Luton.

Richardias.—In order to keep up the supply of spathes from November till late in the spring, two methods of cultivation are called for. For the plants to produce early spathes, they should be rested at this season, removing them for this purpose to a half-shady place out-of-doors, and gradually withholding water; and when the leaves are decayed, turning them on their sides, and if necessary, piling the pots on one another. In this condition, they may remain till the first week in August, when the tubers should be shaken out of the pots, the offsets removed, and the main roots repotted with a moderate degree of firmness in a mixture of loam, leaf-soil, sand, and some horse-droppings rubbed through a $\frac{1}{4}$ -inch sieve. Stand the repotted plants in a cold-frame, and place in the greenhouse in September or early in October. For the main supply of spathes, I rely on those which are planted out in shallow trenches, as for Celery. In these trenches is put a compost consisting of loam, leaf soil, and short-dung, in equal parts, thoroughly mixed together. The plants are taken out of the pots, three-fourths of the old soil shaken off, and all of the offsets removed, and the mass of roots planted 2 feet apart in the trenches, and copious applications of water afforded. Beyond keeping the trenches free from weeds, but little else is needed, unless the season be a dry one, when an occasional watering will be necessary. Early in September, a bright, clean spade, should be pushed down by the side of the plants, 6 inches from the base, in the form of a circle, preparatory to lifting them about the end of the month.

Cyclamens.—The final shift will now be needed by these very pretty, useful plants. Seedlings raised last autumn should be potted in 4 1/2" and 3 1/2", the strongest tuber going into the larger size of pot. See that the drainage of the pots is well done, always placing a handful of finely-broken crocks over the larger crocks. The soil used at the time should consist of equal parts rich loam and leaf-mould, with plenty of sand added. The tubers should not be placed deeper in the soil than three-quarters of their diameter, and the potting should be done with moderate firmness. The re-potted plants may be stood in a warm pit or low house close to the glass; and if round about the pots, common moss be placed to the depth of 2 inches, a genial degree of humidity will be maintained round about them. A temperature of 60° by night, and 65° by day, and shading from bright sunshine, should now be afforded them. J

THE HARDY FRUIT GARDEN.

By H. W. WARD, Rayleigh, Essex.

Young Plantations of Gooseberries and Currants.—The soil between rows of Gooseberry and Currant cuttings (as well as young plants that were struck last year), which were transplanted in rows wider apart last autumn or spring, should be kept well stirred with the Dutch-hoe. The frequent loosening of the surface-soil between young trees, and garden crops generally, serves in a great measure to compensate for a deficient rainfall during April and the four following months. Unless a free use be made of the Dutch-hoe between rising crops during dry weather, the soil, by reason of the combined influence of heat and drought, becomes baked and cracked in more or less degree, and afterwards requires a digging-fork to break the surface, in order to prevent the parching of the soil, and to prevent the reaching the roots through the fissured land, and at the same time preparing the soil for the reception of rain.

Miscellaneous Work.—Water wall-trees at the roots and wash Peach trees overhead with clean water in the afternoon. Thin and pinch off the young shoots, and train those that will be retaining. Thin out crops of Apricots and Peaches in the manner recommended in a previous calendar. In the case of robust-growing Pear and Plum trees which have set heavy crops of fruit, thin the clusters of fruit a little, and in proportion to the number left, so will the size of the fruits be small in size.

FIG. 123.—*OLLARIA STELLULARIS*: HARDY WHITE-FLOWERED SHRUB.
(Exhibited by Messrs. Veitch & Sons at the Temple Show. See Report, p. 353.)

while the amount of moisture should be reduced. If the border lacks moisture, which should be ascertained by the test-stick or a hand-fork carefully used, a thorough application of tepid water, sufficient to moisten it to the bottom, should be afforded. Be careful, however, to afford no water to the soil if it be moist enough for the needs of the Vines, or shanking of the berries will probably occur. If any shanked berries become visible in the buoches, remove them, and thus allow the remaining fruits to fill up the vacant space. Close the vinery moderately early if the ripening of the fruit must be hastened, and in the evening—say, at 7 o'clock—a small amount of air should be admitted at the apex of the vinery. Foster's Seedling and other white Grapes need as much direct sunlight as may be allowed without causing the scalding of the berries.

Late Vinerias.—The Vines in most late vinerias are now in blossom, or they have set; if the former, the same kind of treatment should be afforded as that I have previously advised; and if the latter, let the worthless or badly-set bunches be removed, and a day or two afterwards thin the bunches to the number the Vine or Vines can perfect—and so far as may be pretty equally divided over the Vines. See that all bunch-bearing laterals are properly secured to the wires; and keep all other lateral growth in check by removing them by degrees, not cutting out a large number of them at one time, and thus injuriously checking the growth of the plants. Let the borders, paths, and walls be well damped once or twice a day, and sprinkle manure-water on the paths the last thing in the evening, which is inimical to the dreaded mite (*Tetranychus telarius*) Red-spider. [This insect appears

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY,	JUNE 1	Devon County Agricultural Society's Show (5 days).
THURSDAY,	JUNE 3	Linnean Society.
FRIDAY,	JUNE 4	Royal Horticultural Society meet.
FRIDAY,	JUNE 4	Royal Botanic Society, Lecture.
SATURDAY,	JUNE 5	(Sac. Franc. d'Hort., London, Isle of Wight Horticultural Society meet.)

SALES.

TUESDAY,	JUNE 1	Imported and Established Orchids, at Protheroe & Morris' Rooms.
FRIDAY	JUNE 4	Imported and Established Orchids, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—58° 6°.

ACTUAL TEMPERATURES:—

LONDON.—May 26; Max., 60°; Min., 51°.

PROVINCES.—May 26 (6 P.M.): Max., 58°, The Scow; Min., 49°, Sunning Head.

The Temple Show.

As we write the rain is falling gently enough, we will hope, to satisfy the needs of the gardeners without interfering with the success of the Temple Show, which is in progress as these pages are passing through the press. The show itself is larger than ever, if that be possible within its narrow limits. We are inclined to say it is better than ever. It certainly is so in some respects. It is less crowded, more refined, the general quality is higher, and it is exceptionally rich in examples of good culture. Extensive elimination has taken place, and thus a better view of the plants is obtainable, and there is less repetition of common subjects. In a word, it is more choice. Owing to the comparative absence of crowding, the general effect is superior; but there is still a monotonous flatness, and a lack of those imposing groups which render the continental shows so remarkable.

Of absolute novelties there are not very many. The most striking new plant is a large-flowered variety of *Hydrangea hortensis*, shown by Messrs. JAMES VEITCH & SONS, the leaves of which are very large and dark green, and the barren flowers are over 2 inches across, and of a bright rose-red colour. We hope to figure this next week. Messrs. F. SANDER make a fine display with various species, some of which are figured in the present issue. Among Messrs. SANDER's plants are *Dracena Godseffiana*, like a climbing *Aucuba*, with its spotted leaves and red berries; *Anthurium bogotense*, with deeply cordate, three-lobed leaves, the central one prolonged into a long, spear-like point. *Caladium albanense*, with narrow spear-shaped leaves, wavy at the margins, and of a dull red colour.

Canna indica variegata, said to be imported from the Solomon Islands, has the leaves striped with cream-yellow. The collector says the plant is even more striking than *Heliconia illustris*.

Mapania pandanifolia is a sedge-like plant, with arching green leaves, 2 feet long and 1½ inch wide. When full-grown, it is said to be 4 feet high. *Philodendron imperiale* var. *Lauchena* is a scandent species with ovate cordate leaves, 6 to 9 inches long, bright green, heavily mottled with milky-grey.

Petunia Mrs. Fred. Sander has large full flowers, 4 inches across, and nearly as deep, the colour rich rose-red, the flowers suggesting *Malmalson Carnation*. A white-flowered double *Petunia*, named *Mrs. J. Jefferies*, is also of *Carnation*-like appearance.

Davallia hirta var. differs in habit from the type, and promises to be a useful decora-

tive Fern for the warm conservatory. It is the only plant that obtained a First-class Certificate from the Floral Committee. SANDER's *Streptocarpus* are remarkable for the large size of their flowers. *Arisema Bakerianum* is a near ally of *A. fimbriatum*, but is smaller, with green and brown unstriped spathes, and a hairy spadix.

Rhipsalis salicornioides is a queer-looking Cactus with drooping glass-wool-like branches, and small yellow and orange flowers. *Astille Lemoinei* *Gerbe d'Argent* is a variety with rosette-like flowers.

Clematis Marcel Moser, shown by MOSER of Versailles, has flowers 8 inches across, with numerous spreading segments coloured pale rose, with a broad band of cerise down the middle of each.

Mr. W. BULL, Chelsea, showed *Ficus radicans variegata* with silvery variegated leaves, suggestive of those of *Euonymus radicans*. He also showed *Anemion rotundifolia*, a new introduction with pinnate fronds 2 feet long, each bearing about ten pairs of ovate pinnae, the largest 1½ inches long. *Crimum Moorei variegatum* is a new plant of last year with leaves variegated with cream-yellow.

Phyllocacti are making progress in popularity, thanks to the efforts of Messrs. VEITCH, who have raised many new seedlings, a selection of which were shown, two of them obtaining Awards of Merit.

Streptocarpus were shown, the three sections, *gratus* (*Watsoni*), *pulchellus*, and the *Rexi* group being better than we have ever seen them.

Messrs. WALLACE showed several new forms of *Calochorti*, *Iris Hartwegi*, *I. lupina* (Award of Merit), *I. Korolkowi*, *I. Gatesi*, and *Brodhams*, and an interesting set of hardy *Cypripediums*.

Orchids have, we fancy, been shown more numerous but scarcely more finely on other occasions. The exhibition of these plants is of the first-class order for interest and beauty, and there are one or two gems of the first water.

Roses are marvellous: the groups of Messrs. TURNER, W. PAUL & SONS, PAUL & SONS, MOUNT, among others, are specially worth the attention of the connoisseur. Messrs. W. PAUL & SON show in addition three new varieties, *Empress Alexandra* of Russia, a peculiar orange-salmon colour; *Sylph* and *Medea*, a pale creamy-sulphur colour. Messrs. VEITCH have a mixed group of great beauty, with noble spikes of *Eremurus* arising from a background of *Azaleas* and *Lilics*—and we know not what.

Caladiums are shown in fine condition by Messrs. PEED, LAING, VEITCH, and others, and constitute one of the specialties of the show.

Messrs. CANNELL & SONS distinguished themselves by a group of *Cannas*, the brilliancy of whose colours defy reproduction by any process at our command.

Gloxinias are shown in splendid state by Messrs. SUTTON & SONS, LAING, CANNELL, CARTER, and PEED. Messrs. DOBBIE surprise us with *Dahlias* in May, and Messrs. VEITCH show a curiosity we should be glad to see again—*Campanula Balthiniana*—said to be a hybrid between *C. isophylla* and *C. fragilis*, and having long-stalked ovate leaves, toothed at the margins with a green disc, and a creamy margin.

There are several rockery groups to which special attention should be paid for their beauty, viz., two from Messrs. BARKHOUSE, one from Messrs. CHEAL, in which the rocks wanted more covering; one from the Guildford Hardy

Plant Nursery. These are delightful features, but it is impossible to describe them at length.

There are some other groups more patriotic than tasteful. A beautiful arch of *Asparagus* is ruined by a cockney crown of everlasting at the top; and of another display of a similar character perhaps the less said the better, after we have given due credit to the excellent intentions of the designers.

Outside, Messrs. FISHER, SON, & SIBREAY, have a remarkably fine group of Japanese Maples and other hardy shrubs.

Messrs. BAER & SONS showed a huge leaf of *Gunnera manicata* as big as a good-sized leaf of *Victoria regia*, but in its appearance highly suggestive of *Rhubarb*.

Fruit and vegetables were not largely shown, but the quality was excellent.

Of foreign exhibitors, whom we always like to see on such occasions, we may note Messrs. LINDEN, PIETZ, MOSER, JULES IIVE, and PEETERS.

Notwithstanding the rain which fell during Wednesday, we are pleased to hear that the receipts taken upon that day exceed those taken upon the opening day at any of the nine previous shows.

The Exhibition was honoured by a visit from H.R.H. the Princess of WALES, H.R.H. the Duke of YORK, Princess CHAS. of DENMARK, and Princess VICTORIA. The Royal party were received and escorted through the marquees by Sir TREVOR LAWRENCE, Bart., and several members of the Council, and remained in the gardens for three-quarters of an hour. On Thursday morning the show was visited by Sir WM. HARCOURT.

The arrangements throughout appear to have worked most smoothly, and though the space allowed each exhibitor was considerably less than that asked, we have heard of no unpleasant incident. The bulk of the work has fallen upon the Rev. W. WILKS, Secretary of the Society; Mr. J. WEATHERS, Assistant Secretary; Mr. S. T. WRIGHT, Superintendent of the Gardens at Chiswick, and his assistant, Mr. T. HUMPHRIES.

LINNEAN SOCIETY.—An evening meeting will be held on Thursday, June 3, 1897, at 8 P.M., when the following papers will be read:—1, "Observations on *Ternites*," by Dr. G. D. HAVILLARD, F.L.S., &c. 2, "On the Genus *Ramulina*," by Prof. T. RUPERT JONES, F.R.S., and F. CHAPMAN, F.L.S., &c. A rare Crustacean from Tasmania (*Anaspides tasmanica*), by Prof. G. B. HOWES, F.L.S., &c., will be exhibited.

NATIONAL VIOLA SOCIETY.—The first meeting of the Floral Committee was held in the Reading-room at the Royal Botanic Society, Regent's Park, on Wednesday, the 19th inst. Owing to the early date and untoward season only a few *Violas* were staged, the only one gaining a Certificate being "*Endymion*," a pale yellow, superb bloom of this variety being staged by Mr. W. BAXTER, Woking.

A COURSE OF BOTANICAL LECTURES is being delivered at the Apothecaries Hall, Blackfriars, E.C., by Professor OLIVER, of University College. The course deals with the diseases of plants, and the subject of the first lecture, delivered on Tuesday afternoon, was "*The Plant in Health and Disease*." The remaining lectures will be delivered on consecutive Tuesday afternoons at 3.30, and will treat of "*Witches' Brooms*," "*Some Diseases of Cereals*," and "*The Diseases of Timber*."

BRIGHTON AND SUSSEX HORTICULTURAL SOCIETY.—The monthly lecture in connection with this Society was delivered by Mr. R. DEAN at the Oddfellows' Hall on the 20th inst., the subject being, "*The Gooseberry, its History, Types, Cultivation, &c.*" The chair was taken by Mr. MILES. There was a numerous attendance, and the lecture well received.

FIG. 124.—CALADIUM RONCADOR: DARK ROSE, WITH BLACK AND GREEN VEINS.

(From a photograph by J. Gregory.)

(Exhibited at the Temple Show by Messrs. J. Peed & Sons. See Report.)

FIG. 125.—NEW DWARF CALADIUM THOMAS PEED: BRIGHT ROSE, WITH CARMINE VEINS;
MARGINS SUFFUSED GREEN.

(From a photograph by J. Gregory.)

(Exhibited at the Temple Show by Messrs. J. Peed & Sons. See Report.)

FIG. 126.—DOUBLE BEGONIA DUCHESS OF MARLBOROUGH: ROSE OR SALMON-PINK.
(From a photograph by J. Gregory.)
(Exhibited at the Temple Show by Messrs. J. Laing & Sons. See Report.)

FIG. 127.—SINGLE WHITE BEGONIA LADY HAMILTON.
(From a photograph by J. Gregory.)
(Exhibited at the Temple Show by Messrs. J. Laing & Sons. See Report.)

FIG. 128.—TREVISIA CHLORIS: FLOWERS GREEN. (SEE P. 315.)

A, plant reduced to show habit; B, C, lobes of the lip; D, anther-caps; E, pollinia and caudicle; F, lip-plate, lost (seen from the side); G, glandularium; H, capsule.

FIG. 129.—GLOXINIA PRINCE OF WALES.

(From a photograph by J. Gregory.)

(Exhibited at the Temple show by Messrs. H. Cannell & Sons. See Report.)

FIG. 130 —GROUP OF FIBROUS-ROOTED BEGONIAS.

(From a photograph by J. Gregory.)

(Exhibited at the Temple Show by Messrs. Sutton & Sons. See Report.)

A competition with specimen plants of *Pelargonium* and *Astilbe japonica* was held previously to the lecture, some excellent examples of the former being staged.

YORKSHIRE NATURALISTS' UNION.—The 131st meeting will be held at Cotherstone, for the investigation of the Valley of the Balder, on Whit Monday, June 7, 1897. Permission to visit their properties has been kindly granted by Lord STRATHMORE, Monsignor WRIHAM, and Mr. T. HUTCHINSON. The district for investigation is the picturesque Valley of the Balder, and the gorge through which it flows. Three miles above Cotherstone it is occupied by the reservoirs of the Stockton and Middlesbrough Water Board. The general body of naturalists will leave Cotherstone station upon the arrival of the 11.19 A.M. train, and investigate the Balder Valley as far up as convenient in the time at their disposal, under the leadership of Mr. J. G. BRASS and Mr. RIDLEY. The geological party will be led both on Saturday and on Monday by Mr. W. HEEDMAN, F.G.S., of Newbigin. Mr. W. Y. VITCH also hopes to accompany the party. The geological section will be officially represented by its president, Mr. WM. HORNE, F.G.S. *Botany.*—The botanical section will be officially represented by one of its secretaries, Mr. JOHN FARRAR, F.L.S. The hryological will be represented by Mr. M. B. SLATER, F.L.S., and Mr. R. BARNES. The vertebrate section of zoology will be represented by one of its secretaries, Mr. OXLEY GRAHAM, M.A., M.B.O.U. *Birds.*—Lists have been furnished by Mr. J. W. GELDARD, of Darlington; Mr. JOSEPH WEARMOUTH, of Ravenstonedale (formerly resident in Upper Teesdale); Mr. LITTLE (native of Barnard Castle), Mr. BOROOWDALE of Paisley Castle, and Mr. CHIFFEAUX of Cotherstone. Although notes are given of about 108 birds. Mr. ARTHUR CRAEFTER, West Hill, Halifax, is the secretary for this meeting, and he will furnish applicants with programmes and any information that may be required by intending excursionists.

ANTHURIUM SCHERZERIANUM.—Mr. ELPHINSTON, Shipley Hall Gardens, Derby, sends us some very fine cut spathes of this species, which are marvellous indeed, as compared with the figure of the plant as first introduced, and excellent illustrations of superior cultivation. The specimens before us are all direct descendants of the species, and not hybrids. They are remarkable, not only for size of spathes, but for variety and richness of colouring, varying from pure red and spotted forms, through scarlet to deep crimson. The larger spathes measure about 6 inches in length by 4 inches in breadth.

HERBACEOUS CALCEOLARIAS are less cultivated in gardens than formerly, but they are certainly very showy, and are inexpensive of culture. Mr. H. AUSTIN, Abermaide Gardens, Aberystwith, has about sixty plants in flower in the conservatory, where they are doubtless much admired. From a photograph we have received, and which represents three of these plants, it is evident that the plants have been well grown, and carry a nice wealth of bloom.

THE JUBILEE.—In anticipation of the QUEEN'S Jubilee, Messrs. BRADBURY AGNEW & Co. are preparing a collection of Cartoons from *Punch*, illustrative of events in the long reign in which Her Majesty's personal connection has suggested the subject for the week's picture. Toby, M.P., has written the letterpress explanatory of each Cartoon, in its continuity forming a record of the QUEEN'S reign. *The Queen and Mr. Punch*, which will be published on June 1, contains sixty pictures by LECHE, TENNIEL, and LINLEY SAMBOURNE. The last named artist has drawn a special picture of the QUEEN for the cover of the book.

PLANT PORTRAITS.

CALPURNIA AUREA, *Garden.*—Greenhouse shrub, with a superficial resemblance to the Laburnum.
 CATEPAVA LURIDA V. 1., 1. ardens; 2., Moortchekersky; 3., albo-marginata; 4., Luckienko; 5., Melniko; 6., Hambournto. *Lindley*, t. 41 to 44.

SOCIETIES.

ROYAL HORTICULTURAL.

THE TEMPLE SHOW.

MAY 26, 27, 28.

GROUPS OF PLANTS.

An extensive collection of Japanese Acers came from Messrs. W. FROXON & Sons, Sutton Court Nursery, Chiswick, most of the varieties grown in English gardens being there, viz. *Acer palmatum sanguinifolium*, the deepest coloured variety, a reddish copper; *A. septentrionale*, leucopy purple foliage; *A. palmatum tricolor*, pale pink and creamy white; *A. japonicum laciniatum*, green coloured, holedly divided leaves; *A. palmatum roseum marginatum*, one of the most pleasing of the fine anti-leaved varieties; *A. p. roseum marginatum*, green with red leaf margin, one of the prettiest of them all; *A. p. tricolor*; *A. dissectum purpureum*; *A. palmatum dissectum purpureum*. The group was relieved by a few *patulis* of *Lilium longiflorum* var. *Harrisii*.

A particularly bright group was set up with much good taste by Messrs. W. BALCHIN & Sons, Nurseries Huscock, Hive and Brighton. The groups consisted of pyramids composed of *Erica verticosa magnifica*, *E. Cavendishii*, and *E. Spenceri*, a lovely rose-coloured flower. The middle pyramid was built up of *Rhipis salicifolia* in the central place at the back, then a line of *Phloxesca prolifera*; below this a circular band of *Bonia serrulata* with a plant of *Pimelia decussata* at each end; then a row of *Ophiopogon Jaburan variegata*. Ferns filled up the intervening spaces, and the group was fronted by *Coprosma Baneriana variegata*, *Lechthymia biloba major*. Such a fine display of these old-fashioned hard-wood plants is seldom seen.

Messrs. R. & G. CUTBUSH had at one end of a long table filled with Orchids a removal group of *Azalea rustica*, a. mollis varieties, and crosses between these most dwarf examples growing in pots and pans. *A. rustica floreplo Normae* is a bright salmon red; *A. r. Martii* is a variety, the reverse of the outer segments yellowish white; *A. r. p. l. Ribera*, bright yellow; and *A. r. Meene*, white suffused with pink inside and yellow outside, were the best; *Ghent Azalea Pallas*, yellow and orange red. Of *Azalea mollis* there was great variety, and these, having large flowers, make a more gorgeous display than the other varieties which the group consisted. For indoors early work, and for planting in beds outside, nothing can excel these plants in brilliancy of effect.

Messrs. F. SANDER & Co showed a number of plants of a double flowered variety *Potamo*, named Mrs. Fred Sander, a showy pink-coloured flower, with fringed petals, closing inwards, and forming a globular flower-head. Other plants in this group of miscellaneous plants were a fine large *Davallia hirta*, see fig. 131, p. 355, a densely habitated Fern of imposing appearance, the decomposite pinnæ springing from the rachis in close order, and being thence less much serrated.

Begonia Silver Grey, a handsome foliage variety of dwarf compact habit; a white *Polyantha Rose*; *Sander's Snowball*, a profuse bloomer; *Anthurium Rothschildianum* in a number of varieties. These showed different degrees of spotting, and in one case the absence of any. In the case of spotted varieties the ground colour is white, and if sometimes suffused with red, the spots are in all cases of a scarlet colour.

Several *Streptocarpus* with large flowers, including *Sander's White*, which is nearly pure, but less in size than some others; *Dracena Sanderiana* a beautiful example four feet high a three feet wide; *Caladium speciosum*, white green with broad creamy-white veins; *Caladium Allouense*, possessing narrow leaves of red and green both illustrated in fig. 118, p. 340; *Begonia Captain Holford*, a silver-leaved variety with crisp leaves marginated; *Wendlandia*, also silver; *Magnolia grandiflora*, see fig. 122, p. 349, a *Dracena*-like plant, but caulescent as seen, with narrow (1 inch) leaves, the longest of which were 24 inches long; *Anthurium bogotense*, a bold habitated imposing looking species with univulve leaves, set on neat branched pedicels; *Dracena Godoliana* (in fruit see figs 119, 120, p. 347, a plant with green coloured oval leaves, set in pairs and triplets on slender branches, a distinctly ornamental species.

Begonia Comtesse de Teilsou, rich, deep green leaves edged with a darker tint of green; a distinct, strong plant; *Erichecia Fascinator*, with pale green leaves and close compact habit; *Begonia Duches* of Sutherland, green leaf, digitate in form, and blotched with white; a plant of *Rhipisalis Salicoides* in flower; a new variegated-leaved *Camelia*, the variegation consisting of green and creamy white in suffused stripes, more or less distinct; *Philodendron imperiale* var. *Luxumum* in which the leaves of the type are suffused with a silvery tinge; *Begonia Windsor Geny*, pink on silver. The remainder of the plants consisted of *Anthurium Scherzerianum*, *Heliopsis*, an *Abutilon* with variegated leaves, *Asparagus plumosus*, *Nepenthes* a few; *Petunias*, *Orchids* in variety; the tricolor form of *Hypericum Morsinianum variegatum*, the colour of the leaf of which comes out well under full sunshine.

Messrs. JAS. BARNBROOK & Sons, nurserymen, York, had erected out of cork and covered with fibrous material, on which were planted out Ferns, small Palms, *Silphofloria cuneata*, *Odontoglossum crispum* and other *Odontoglossa*, *Maranta Veitchii*, *Cypripedium bellatulum*, *C. Rothschildianum*.

Miltonia vexillaria in variety, *Sobralia macrantha*, *Cattleya* in variety, *Palms*, *Caladium argyrites*, *Asparagus plumosus*, *Azalea indica roseo-ora*, &c. As an example of a method of making a wall, &c., with flowering and foliage plants it was an instructive feature.

Messrs. W. & J. Brown, nurserymen, Stamford, Grant-ham, and other places, arranged a small group at the end of the central table, that consisted of a quantity of furnishing plants, such as *Carnations*, *Zonal Pelargonium* *Hyacinthus*, *Solifloria*, *Geranium*, *Centauria*, *Peonies*, *Zinnias*, and *Chrys. Turner*; *Machet Mignonette*, *Saxifraga pyramidalis*, *Lilium longiflorum*, a twofold of blooms of *Rose Niphetos*, decorative *Pelargonium* Mrs. W. Wright, *Kalosanthes*, M. Pfitzer, with light red flowers, and K. M. Buchner, with white and pink flowers; small Ferns associated with *Dactylis glomerata* variegated.

Messrs. T. CURTIS & Sons, Tunbridge Wells Nurseries, exhibited a group of Japanese Acers, which matched those of Messrs. FROXON on the opposite side of the entrance, the varieties being almost identical, but the plants generally were of greater age and size.

Messrs. WILLS & SICKS, Onslow Crescent, St. Kensington, put up a group at the end of the large marquee, as wide as the same, and measuring about 10 feet from the front to the back. The general idea was that of specimen foliage plants of graduated height arranged at a distance of one to three feet apart. Between the plants the intervening space being covered with *Maidenhair Fern*, *Salignella douglasii*, *foliate Begonias*, small plants of the dwarf *Maranta* and *Kerchovenia*. The principal plants were a fine *Aralia Clabrieri*, about 10 feet high; *Pilea rotundifolia*, *Aralia nymphefolia*, *Anemosa sativa variegata*, *Alouca Lindleyi*, *Thunbergia alata*, *Demarexia polyandra*, *Kentia Edmonstone*, a fine specimen 12 feet high, and of nearly the same stretch of crown; *Anthurium crystallinum* a faultless example; *Dieffenbachia Bausei*, *Alouca Rodrigueziana*, *Dracena latifolia*, very fine; and an unusually nice plant of *D. Goldiana*; *Holconia filistylis*, *Yucca filamentosa*, a perfect *Sandersonia*, *Alouca Hart*, *Alouca fortensis*, *A. Thibautiana*, *A. Mrs. Martin Cluzac*, a striking plant; *Phrynium variegatum*, *Calamus longipes*, *Stenonema grandifolia*, a striking broad-leaved plant; *Alouca Sciendi*, *Kentia Canterburyana*, a perfect example of this well known species of *Palm*; *Chamaerops staurocampa*, a *Palm* of bold contour; *Dracena Sandersonia*, *Martynia coccinifolia*.

Mr. W. LEROUX, florist, Putney Park Lane, S.W., arranged a mixed group of flowering and foliage plants. The salient plants were very fine, *Lily* of the Valley in groups, dropped in among the *Maidenhair* and *lowly plants*; *Azalea mollis*, with heads of about 4 feet in diameter, six bright coloured varieties, and a large number of small examples; *Crotons*, *Dracena Gailloylei*, masses of *Lilium longiflorum* var., *Asparagus plumosus*, ornamental leaved grasses, *Aralias*, &c., and at the back a number of *Palms* of various species.

Messrs. JAS. VETTER & Sons arranged a grand display of hardy flowering and picture plants of the most beautiful quality of Japanese Acers, *Prunus Pissardi*, and *Bambusa*. The back row plants consisted of very finely flowered *Hydrangea paniculata*, *Genista scoparia Andreum*, *Lilium longiflorum* var. *Harrisii*, *Azalea mollis*, *Cytisus precox*, *Halesia terrarum* in bloom, *Clatonia alnifolia*, a stout bush of *Olestra stellaris*, see figs 123, p. 347, white flowers; *Clatonia alnifolia*, a bushy plant of the variety *Montan* *Peonies* with deep rose and pale blush coloured, grand flowers; then came hybrids of *Azalea mollis* and *A. sinensis*; *A. rustica*; *A. r. duo pleno Ribera*, with bush coloured flowers appearing in great numbers, which received an Award of Merit. Facing these were *Hydrangea* *Prunus Pissardi*, *Bambusa*, *Erica verticosa*, with bright pink abortive flowers and numbers of others in the centre of the corymbis; *Weigela rosea* *Eva Ratke*, with deep crimson coloured flowers; *Olestra Huxleyi*, *Arum* *Donax variegata*, *Cytisus purpureus flore albo*, some *Lily* of the Valley, with very large flowers, some plants of *Daphne Quercifolia* with brightly flowering *Eromurus himalaicus* very fine large and tall spikes; *Andromeda speciosa cassinifolia*, the white flowered *Azalea viscosa*, and *A. rosiflora* with double flowers of soft pink tint. The crosses of *Azalea mollis* and *A. sinensis* are particularly productive of rich colours, and a large flower, pleasing variety. *Spiraea astilboidea floridissima*, a desirable variety. It does not differ from the type except in prolificacy of blossoms.

Some hardy flowering shrubs shown by Messrs. J. VETTER & Sons, for which space could not be found in the marquee, were placed outside, among them being a plant of *Chionodoxa virginea*, *Galearia arborescens purpurea*, *Hypericum Morsinianum*, *Lithospermum prostratum*, *Cytisus elongatus*, *Geausta pilosa*, and others.

JOHN WATERER & Sons (Limited), Bagshot, showed a comprehensive group of Japanese Acers in small examples.

Mr. LEONARD B. HONEY, of Gunning Hill, near E. J. Holford, (see fig. 124, p. 347), exhibited outside one of the tents a great group of Cape *Pelargoniums* with most fine foliage, admirably grown and trained, and mostly of an unusually large size. He also showed four single, white-flowered examples of *Marguerites* in full flower; and five well-foliated colonial bushes of small-leaved *Aspidistra* *Aspidistra* var. *Cliffordii*, *Phloxes*, *Flanra*, *Sax* & *SUNWAY*, *Humboldt*, near Sheff field, arranged a long bed in the open air with chiefly Japanese Maples, Tree Lvs., &c. The Maples consisted of large and small plants of the better known varieties. Other plants remarked were *Rubus fruticosus variegatus*, *Andropogon japonicus variegatus*, *Myrica verticillata* var. *Cliffordii*, *Thunbergia*, and others. *Lilibeopsis Boniana*, *Sambucus racemosa plumosa* ather, a good shrub for cold districts, *Cornus Spachii aurea scabra variegata*, used in the North

instead of the leader *Earl Nequedo variegatum*, which it greatly resembles in general appearance; *Betula purpurea*, noted in well coloured examples. The Tree lves are excellent for covering large spaces under trees, relieving the monotony of the common lvy, and for furnishing heds.

Mr. H. HOWELL, King Street, Hamersmith, had a small group of Ferns in flower.

The GUILDFORD HARBLY PLANT NURSERY Co. had a background of Conifers and other plants, and a foreground of an Alpine garden planted with many subjects. Chief among them *Androsace*, *Anemone*, *Arenaria*, *Abrietta*, *Cypripedium*, *Platanus*, *Erigeron*, *Centauria*, *Lithospermum*, *Malva*, *Ranunculus*, *Asiatica*, in variety, *Veronica*, *Viola*, &c.—a charming feature well worked out.

Messrs. BACKHOUSE, of York, had also a delightful group of alpinas, artistically arranged.

ORCHIDS.

That the show of Orchids was one of the best seen at the Temple was the opinion of connoisseurs, and the remark, well merited by the show in general, was applicable in the highest degree to the splendid group staged by Sir FREDERICK LAWRENCE, Bart., the President, whose collection was one of the finest, and certainly the most interesting to the plant-club group staged; and the most judiciously arranged. The Orchid-grower, Mr. W. H. WITTE, should be complimented on the admirable effect made. In the background, the fine specimens of *Thunias* were very effective, among them being the purple *T. Bensoni*, and the lighter-coloured *T. pyrarnicum* and *T. Marshallianum*. He and there appeared the most effective arrangement of specimens of *Epidendrum radicans*, and *E. O'Brienianum*, the purple *E. arachnoglossum*, and the singular *E. Mooreanum*; and richness of colour was made by the fine specimens of *Cattleya Mossii*, *C. Mendellii*, &c. Throughout the group, not less noticeable than the perfection of the flowers, was the remarkably fine condition of the buds bearing them, and this applies especially to the fine specimens of *Cypripedium* of many kinds, both species and hybrids, the foliage of *C. Lawrenceanum* and other marble-leaved species being very beautiful. Some of the most remarkable were *C. Stonei*, with twenty-four flowers, and a lesser plant of a magnificent variety of the same species, *C. × concavilveum*, *C. × Eleanor*, and *C. × Leahyanaum*.

The Masdevallias were represented by a very fine collection, the varieties of *M. Harryana*, supplying the brilliant scarlet, purple, and marvellous colours. Of them, *M. Harryana fuscoculata*, a large scarlet with yellow tube, was the finest. Of the lesser kinds the most interesting specimens were *M. bicoloripolia*, *M. × Mundyana*, *M. × Henriette*, *M. eudata Shuttleworthii*, *M. × Garreana*, *M. Harlesna*, &c. Other remarkable things were splendid forms of *Zygopetalum*, *Pteronidium*, some pretty *Epidendrum Andresii*, and its hybrids *E. × Andresii-Walshii* and *E. × elegantissimum*; *Laelia Cattleya × Thosbe*, a fine *Phalenopsis Lindeniana*, *Maxillaria Sanderiana*, some very fine *Oncidium concolor*, and other *Oncidiums*, *Cattleya Mossii*, &c., and a fine display of *Odontoglossums*, *Dendrobiums*, &c.

Of special botanical interest were the singular green *Aeranthium zygopetaloides*, which may be *A. arachnites*, the curious *Fria oroides* of October, *Stenopogonella longicauda*, and the new purple white *S. longifolia alba*; *Microstylis macrocheila*, the charming dwarf *Trichocentrum longicaudum*, a tuft of fleshy leaves and pretty white long-spurred flowers, with blood-red blotches; a *Lycaete jugosa*, with very clear white flowers; a *Polypodium rotundatum*, with a lot of other curious and pretty plants, including a pot full of *Neottia nidus avis*, the Bird's-nest Orchid.

Baron Sir H. SENNEN, De Dell, Eggham (gr. Mr. H. Ballantine), in spite of the great draw made on his collection by the Hamburg show, arranged a similar space to that he filled in previous years, and staged a grand group, in which the magnificent forms of *Odontoglossum* for which his collection is noted were a fine feature. Some of the most beautiful were the heavily blotched *O. crispum Sanderianum*, *O. e. Ballantini*, and *O. e. mirabile*, the last-named being very remarkable. Of the fine white forms *O. e. magnificum* was the best; among other species very fine were *O. scoparium Vuykianum*, with clear purple flowers; two plants of *O. × elegans*, some fine *O. polyanthum*, *O. Hallii*, *O. ramossissimum*, and other species. The staging of the group was most effective, in the centre being a number of *Vanda* trees, and on either hand tastefully arranged masses of *Oncidium*, *Laelia purpurata*, *Cattleya Mendellii*, including *C. m. alba*; *C. Skinneri*, and its white variety; showy *Masdevallias*, &c. Some of the most remarkable plants were a splendid specimen of *Cypripedium calossum Sanderi*, with two very large flowers; the wonderful fringed *Laelia Cattleya × Digbyana*—*Mossii*, some well-flowered *Laelia purpurata*, *Laelia Mendellii*, *Phalaenopsis Angulata uniflora Turneri*, *Laelia Cattleya × Hippolyta*, *Epidendrum × elegantissimum* varieties, *E. Randii*, *Celebryne Dayana* with twenty-four spikes, which secured a Cultural Commendation, and *C. Dayana*. The Dell variety, a fine form, which received an Award of Merit, some fine *Cochlidia Nozdana*, &c.

Of special botanical interest were the feathery-ribbed *Bulbophyllum barbigrum*, the singular *Odontoglossum unguiculatum*, and the little scarlet *Hexisea bidentata*. On the same site, Mr. W. H. ELMS, Esq., Hazelbury, Dorset, arranged a pretty group of those *Odontoglossums* which he knows so well how to cultivate. The plants were fine in quality throughout, and *O. crispum Ellisi*, with heavy blotches on each segment, a great beauty. Also in the group were good *Mitonia vexillaria*, *Odontoglossum nebulosum*, *O. chloratum*, *O. Hallii*, *O. coriolum*, and other species.

Next came a group of fine old species set up with *Pantheum* and *Maidenhair*, by Earl Pease, Son House, Brentford (gr. Mr. Wythes), and in which *Laelia purpurata*, *L. tenobrosa*, the large flowered *Cattleyas*, *Cymbidium Lowianum*, *Oncidium sphaecolatum*, *Dendrobium Bensoni*, *Brevissia verucosa*, *Oncidium concolor*, and other standard kinds were included.

Then followed a pretty group staged by a new exhibitor, W. N. GILLET, Esq., Fair Oak, Bishopstoke (gr. Mr. Carr), and very creditable it was, and admirably arranged. In it were good *Cattleya Mossii*, *Laelia purpurata*, *Odontoglossum crispum*, *O. Pescatorei*, *O. hastulatum*, *Mitonia vexillaria*, *M. Phalaenopsis*, and other showy, species all well grown.

On the other side of the centre stage, Messrs. F. SANDER & Co. had a very charming group composed of all good things, and very tastefully set up in a bank of green wood Moss. Among the best were undoubtedly the white *Cattleya Mossii* *Benechiana*, and the collection of the late G. HARRIS, Esq., and which is perhaps the best known form of it. The grand specimen bore thirteen flowers and buds, and was an excellent example of a rare, yet showy Orchid; *Laelia Cattleya × The Queen*, with large dark velvety rubbed lip; *L. C. × D. S. Brown* (*C. Triman* × *L. C. × elegans*), with very highly coloured, well expanded lip; *Cattleya Bossii* (*Leopoldi* × *intermedia*), a neat and prettily spotted flower; a pan of the handsome *Anectochilus Sanderiana*, with bright emerald-green foliage, veined with silver, and marbled with olive-green; a fine pan of *Stenoglossis longifolia*, and a plant of *S. longifolia alba*; fine specimens of *Benechiana*, with highly coloured, well expanded lip; *Cattleya Lelia tenobrosa magna*, *Epidendrum Randii*, *Cattleya Schroederia alba*, a fine specimen of *Maxillaria Sanderiana*, three distinct and beautiful forms of *Mitonia vexillaria*, the pretty *Phalaenopsis bicolor* *Owonia*, two grand specimens of *Dendrobium infundibulum*, and mingled with this group of new plants were a number of pretty and rare species.

Messrs. B. S. WILLIAMS & SON, Upper Holloway, staged an extensive group, in which there was great variety. Among the *Cattleyas* were fine varieties of *C. Lawrenceana*, *C. Mendellii*, and *C. Mossii*, *C. Mossii purpurea* being of unusual colour. Among the *Odontoglossums* were good specimens of *O. arachnites*, *O. Pescatorei*, *O. crispum*, &c. The *Cypripediums* were represented by *C. × Alumum*, *C. barbatum splendens*, *C. × vernicum*, *C. Mastersianum*, *C. × Io grande*, *C. × grande*, *C. × Harrisianum superbum*, *C. × calathinum*, *C. Chamberlainianum*, *C. × Dombianum*, *C. exul*, *C. Boxallii*, &c. Other good things were *Angolia Chowii*, *Asiatica Fiedlingii*, *Alta aurantiaca*, *Cochlidia Nozdana*, a very peculiar copper-tinted *Phalaenopsis Sanderiana*, *Oncidium concolor*, *O. Marshallianum*, *O. superbum*, a splendid *Trichopilia crispata*; the background being occupied by some very fine *Vanda* trees and *V. avasiis*, not usually seen in such good condition.

EMMA WOODROE, Esq., Hereford Hill, Wiltshire (gr. Mr. Holbrook), showed his unique *Laelia purpurata* *Asworthiana*, illustrated in the *Gardener's Chronicle*, July 11, 1896, p. 39, and whose peculiarity is the extraordinary development and colouring of the petals, which imitate the hair of a cat. Mr. Woodroe also showed a singular double-lobed *Laelia* *intermedia*.

Sir FREDERICK WIGAN, Clare Lawn, East Sheen (gr. Mr. H. Young), staged a very fine and well-arranged group, in which the *Cattleyas* were excellent, especially *C. Mossie Beatrice*, which is a very handsome and large flower; a fine *C. m. alba*; a very fine flowered *C. m. alba*, and *C. Schilleriana*, and some grand forms of *C. Mendellii*. The central figure was a very fine *Cymbidium Lowianum*, with numerous spikes; a fine plant of *Cypripedium × Gertrude Hollington*, with a plant of the tiny little *Fria extortiva* perched on the bell-glass covering it; the singular *Celebryne Schilleriana*; some very fine *Odontoglossums* one grand form of *O. Wilckeanum* with specially noteworthy; fine *Laelia purpurata*, *L. tenobrosa*, &c.

MALCOLM S. COOKE, Esq., Kingston Hill (gr. Mr. Buckell), had a group of *Odontoglossums*, *Cattleyas*, *Mitonia vexillaria*, *Masdevallias*, &c.

M. FINEY, Argentville, France, showed a number of white flowers of *Cattleya Mossii*, and a very large coloured form named *C. M. grandiflora*.

R. BROMMS-WHITE, Esq., Arddaroch, Gariochhead, showed *Odontoglossum crispum* *Starlight*—the gem of the show—an unique form, with grandly-shaped white flowers, slightly tinted with pink, the petals fringed, and each segment bearing a pair of small red-brown blotches, quite unlike any previously seen.

M. PETERS, St. Gilles, Brussels, showed *Odontoglossum crispum* *Petersii*, a handsomely blotched variety; *O. e. Mrs. Peters*, very distinctly blotched and shaded with rose colour; *Mitonia vexillaria radiata* *Hyena*, and *M. e. virginialis*.

His grace the Duke of SUTHERLAND, Trentham (gr. Mr. P. Blair), showed the noble white *Odontoglossum crispum* *Princess of Wales*, with flowers 4½ inches across.

M. JULES VIE-LEVEN, Couperie, Ghent, Belgium, showed some fine *Odontoglossums*, among them *O. Wilckeanum albens*, a grand form of *O. × excellens*, *O. luteo purpureum* *seeboldii*, the blotched *O. crispum*, *Hempsterniana*, *Cattleya Blenna gigantea*, and the bright scarlet *Masdevallia ignea Vuykiana*.

G. W. LAW SNOWFIELD, Esq., New Hall Hilly, Rawtenstall, Manchester (gr. Mr. Shill), showed *Laelia Cattleya × Tyntasfeldensis*, a splid ntid hybrid of unrecorded parentage, but evidently some cross of *Cattleya Dowiana*. The sepals and

petals were cream-colored, tinged and veined with rose; the beautifully-formed crimped lip, velvety, ruby-red, darkening to maroon, the base showing a yellow marbling. A. WARRBORN, Esq., Vine House, Haslingden, showed *Laelia purpurata fastuosa*, a broad-petalled, darkly-coloured form.

Mr. JAS. CYPRIER, Cheltenham, staged a very pretty group arranged with his usual skill. In the group were a great variety of fine forms of *Laelia purpurata*, some elegant plant of *Epidendrum radicans*, *E. O'Brienianum*, and other tall-growing species; *Mitonia vexillaria*, splendidly flowered *Cattleyas*, *Trichopilia crispus* *superba*, *Cattleya Victoria*, *Cymbidium macranthum*, *O. concolor*, and other *Oncidiums*; *Masdevallia Vitellii grandiflora*, *M. × Itadiff*, some fine *Odontoglossum crispum*, &c.

In Tent 4, Messrs. L. LEWIS & Co, Southgate, had a very effective group, noticeable in which were *Laelia purpurata* *Rossii* in fine colour; *L. p. Bella*, a pretty light variety; *L. p. Milisiana*, with a very long lip; *Cattleya Mendellii* in a very pretty blush white flower; *C. Mossie perfecta*, also a fine light form; some grand *Oncidium varicosum*; *Cypripedium × Gertrude Hollington*, and other fine *Cypripediums*, notably the pretty *C. × Aylindii*, the singular *Cymbidium canaliculatum*, *Odontoglossum crispum*, and other *Odontoglossums*.

Messrs. J. CHARLESWORTH & Co., Heaton, Bradford, staged a fine group in which *Livio-Cattleya × Lady Wigan* (*L. purpurata* *Russelliana* × *C. Mossie aurea*) represented one of the very best plants in the show. Its large flowers had the sepals and petals fully displayed, of a clear bluish white, the gradually formed, circular lobes of lip, crimped at the edge like the petals, and tinted of a clear pinkish white with some purple markings on the disc, and a rich yellow interior to the tube of the lip. In the group also was the fringed *Laelia Digbyana*, some fine *Cattleya Mendellii*, and other *Cattleyas*; *Cypripedium × Leveynianum*, the pure white *C. bellidulatum* album, the fine white *Cattleya Beckiana*, with very dark blotches on each segment; *O. e. magnificum*, one of the largest and best whites; *Odontoglossum Pescatorei* *Burkenslawianum*, a lovely variety, blotched with purple; the pretty yellow red *Sepholia-Laelia × Marriotiana*, *Spallothopsis Kimballiana*, &c.

Messrs. LAYTON, The Culture Internationale, Brussels, showed a group of grand forms of *Cattleya Mossie*, *Odontoglossums*, &c. Remarkably handsome were *Cattleya Mossie Queen Empress*; *C. M. alba aurantiaca*, *C. M. Moorebeckiana*; *Odontoglossum Pescatorei imperiale*, a large flower heavily blotched with purple; and some fine *O. concolor*.

Messrs. HUGH LOW & Co., Clapton, had a very extensive and fine group. Among the *Odontoglossums*, *O. crispum* *Queen Victoria* was one of the very finest blotched varieties yet seen, the blotches very dark, and yet bright. In the group were grand *Laelia purpurata*, and large-flowered *Cattleya*, *C. Mossie Mrs. J. Bradshaw*, *C. m. alba*, and *C. m. Schilleriana*, and other rare *Cypripedium* × *Gertrude Hollington*, and Mrs. Carr *Cypripediums*; a fine example of *Phalaenopsis intermedia* *Brymeriana*, a plant of the fine *Celebryne asperata* (Lowii), and other interesting species.

W. THOMPSON, Esq., Walton Grange, Stone, Staffs (gr. Mr. W. Stevens), had a group of grand *Odontoglossums*, each with a distinct character, and showing the splendid colouring to which they are best adapted. Specially fine were *O. scoparium aureum*, *O. excellens* *Thompson*, *O. crispum Annie*, and several very brilliant *Cochlidia Nozdana*.

Major JOSEY, Sunningdale Park, Sunningdale (gr. Mr. Fred J. Thorne), had a small group of grandly-flowered plants, viz., *Luddemannia Lehmanni* with three spikes, two splendid *Angolia Chowii*, large *Mitonia vexillaria*, *Dendrobium barnesum* *glebanum*.

R. I. MEASURES, Esq., Rogate, Sussex (gr. Mr. Wooton), showed two plants of the splid lid *Cypripedium × Chapmanianum*, which recently got an Award of Merit, but is now a first-class Certificate. Also *C. × Chapmanii* and *C. × Rhonia* (*harbatum rubrum* × *Adocryne*), also fine.

Messrs. CAFFEY, Tambridge Wells, showed two fine specimens of *Cypripedium calossum Sanderi*.

Mr. E. E. TYNESHED, Ashton on-Mersey (gr. Mr. T. Stafford), had a small group, in which were *Cattleya Schilleriana*, *Hardy's* variety, the largest and best form which has yet appeared; *Cypripedium calossum Sanderi*, *Laelia purpurata* *Bachousiana*, *Cypripedium × Goweri magnificum*, *C. vexillarium superbum*, and other good things.

Messrs. JAS. VERTON & SONS, Royal Exotic Nursery, Chelsea, showed their first hybrid *Spallothopsis*, *S. aureo × Vieillardii*, a charming novelty, with yellow flowers with purple marks on the petals and lip.

THOS. STANTER, Esq., Stand Hall Whitehall, Manchester (gr. Mr. W. Stevens), showed a fine *Cypripedium × concolor bellidulata*, a very handsome hybrid.

Mr. EDW. MOSE, Esq., Avenue Road, Regent's Park (gr. Mr. Clarke), had a neat group, with *Celebryne Dayana* in the centre, and around it, good *Cattleyas*, &c.

ROSES.

Groups and out flowers were well up to the usual standard; indeed, so far as the out blooms were concerned, there was a great improvement, the more frequent use of bright Hybrid Perpetuals making a much better effect.

Messrs. W. PAUL & SON, Waltham Cross, had a most effective group of plants, baskets of cut Roses, and twelve large boxes of cut flowers. The most noticeable of the latter were

Margaret Dickson, Triomphe de Caen (a beautiful dark crimson), La France, Medoa, Eugénie Verdier, Maréchal Niel, Prince C. de Rohan, and Danmark. Among pot plants, Crimson Rambler, Spenser, Duke of Teck, La France of '95, and Medoa, were especially good. Syllip, a new Rose with deep salmon-pink centre, is promising; but the only remarkable novelty in Roses was Tea Empress Alexandra of Russia. This is good under glass, as seen here, and Mr. W. PAUL informs us is even better in the open ground. "A rich lake-red, shaded with orange and fiery crimson," is Mr. PAUL's description. There is a distinct shade of copper and salmon pervading the whole flower, and it is one of the most distinct new Roses seen for many years.

A grand group came from Mr. C. TRENSE, Slough, who again exhibited Crimson Rambler in every form: as arches, standards, pyramids, &c. JUNG, Celine Forestier, Comtesse de Sereny, Marie Baumann, Ulrich Brunner, Mrs. John Laing, Marchioness of Londonderry, and Souvenir d'un Ami, were among the best plants. Thalia, the new White

Catherine Mermet were very good and clean. Excellent flowers of Gustavo Pizagnone, Earl of Dufferin, Conato Raimond, The Bride, Catherine Mermet, Lady Mary Fitzwilliam, Anna Olivier, Jean Ducher, and Ulrich Brunner were found among the other boxes. A great improvement was made by placing small groups of long stemmed flowers between the boxes, and backing the whole with some well-grown Crimson Rambler. For a small and narrow space, this was one of the most effective groups in the show.

HIPPEASTIUMS.

As representative of this section of decorative plants, not a single specimen in pots was staged, but some cut blooms staged on boards, as in the case of Daddias—an unsatisfactory method of exhibiting these flowers—came from Messrs. KELWAY & SON, nurserymen, Langport, but they fell behind in quality what we have been accustomed to see from Chelsea and elsewhere, though two or three varieties were staged for the consideration of the Floral Committee.

of plants of the pale yellow Duchess Consuelo, the name of which has recently been changed at the request of Her Grace; and also finely bloomed plants of the new pink Malmson Princess of Wales.

Messrs. W. CUTBUSH & SON, The Nurseries, Highgate, had a large group of Carnations close by, comprising in all some 800 plants, including many of the common Malmson, Princess of Wales, Lady Grimston, Andrew Noble, a soft rose self border variety, Reginald Godfrey, Germania, which yet stands as the premier yellow self; La Fillette, soft pink suffused with reddish-rose; General Stewart, dark; and the heavy red-edged Picotee, J. B. BRYANT. Another week was required to have the plants fully in bloom.

Mr. J. FORD'S, Borelouch Nurseries, Hawick, had a group of a red Carnation unnamed, with an edging of Polyantins of various colours.

Messrs. BUCKROSE & SON, York, had a somewhat coarse-looking yellow self Carnation, named Margery Pearce, which has a defective calyx. Much better in every way was Primrose

FIG. 131.—DAVALLIA HIETA VAR.

(Exhibited at the Temple Show by Messrs. F. Sander & Co. See p. 352.)

Rambler from Germany was shown in this group. It is promising as a climber, but very small and thin compared to rambler.

Messrs. PAUL & SON, Cheshunt, filled a corner with a very prettily arranged lot of plants and baskets of cut-flowers. Madame de Wattenole, Souvenir d'un Ami, Alphonse Souper, Captain Haywood (a very bright H.P., and, if thin, is so well built up as to hide this defect); Maréchal Niel, Elise Fugier, Madame Charles, and William Warden were all very good. A specimen of the White Maréchal Niel did not impress us as being any real improvement upon the parent flowers often found in the old variety.

Mr. W. REMSEY, Waltham Cross, had his new H.P. Mrs. Ramsey in good form, and clearly proved its adaptability for pot-work in almost any form. This is a clear pink, with some of the greenest foliage found among Roses, and is mildew proof. Climbing Star of Waltham is bright but thin. Some excellent cut blooms of Maréchal Niel were staged in this lot.

By far the best cut blooms came from Mr. G. MOUNT, Canterbury, who had both Teas and H. Perpetuals up to summer form; his boxes of Niphotos, Mrs. J. Laing, and

CAULICOLARIAS.

Of these several collections were staged, and as they were at their best—fresh and bright—they were seen to the best advantage.

Messrs. J. JAMES & SON, Woodside, Slough, had several large and small specimens, dwarf, compact, well grown and flowered, the flowers of medium size, well formed, varied, and striking in colour.

Messrs. JAMES CARTER & CO., High Holborn, W.C., had a large batch of plants like the preceding, dwarf, compact, fine in quality, and very even as well as varied in colour. About one hundred plants comprised this fine group.

Messrs. H. CANNEL & SON, nurserymen, Swanley, had four dozen specimens in excellent character, well grown and bloomed. It was satisfactory to note there was a comparative absence of those hose flabby cotyledons which are sometimes exhibited.

CARNATIONS

and they are always popular at a Temple Show.

Mr. WILLIAMS, gr. to the Duke of MANSFORD, Blenheim Park, Woodstock, had at one end of the Orchid tent a group

Queen, from Mr. F. PEARNS, Regent Street, Leamington. This is of excellent habit, very free, pale yellow in colour, and does not split its calyx. Being so much paler in colour, it cannot rank so high as Germania, but it will make a useful variety for cutting from.

Mr. GEO. STEVENS, St. John's Nursery, Putney, had a group of Carnations, including Miss Nicholls, bright red; Ruby, a purple self; Primrose, yellow self; Mrs. Geo. Stevens, a rose self; and Miss L. STEVENS, a rose-bud.

From Mr. C. BIRK, gr. to MARJORIE R. SMITH, Esq., came Bonhomme and Bina, two very promising white selfs, distinct, the petals of the last named slightly fringed; and Artemis, a bright pale red fancy variety, daked with slate.

CLEMATIS.

As a rule, these were not up to the usual standard. A collection of some fifty specimens of these came from Messrs. RICHARD SMITH & CO., St. John's Nursery, Worcester. The leading varieties were Princess of Wales, light lavender; Gloire de St. Julien, delicate lavender; Blue Gem, pale bluish-navy, with large well-formed flowers; Sensation, dark violet-navy; Imperatrice Eugénie, white, with fine

large, well-formed flowers; and the following double varieties, Mrs. Geo. Jackson, white; Countess of Lovelace, mauve; and Leticia Lemonie, white; and Misses J. G. Messrs. G. J. Van der Meer, nurserymen, Woking, had plants of two of their new varieties of *C. coccinea*, viz., Duchess of Albany, pink, with a rosy-crimson flame to each segment (Award of Merit); Countess of Onslow, crimson; and Duchess of York, white, with a pink flame. The chief interest in this class of plants is the two new varieties sent by M. JEAN MOSER, of Versailles, though they were much alike. The best was Mareel Moser, a spring-flowering type, the flowers blush, with a broad flame of pale crimson, very distinct and attractive (Award of Merit). NELLY MOSER had flowers of a white ground, each segment having a slightly narrower flame.

PETUNIAS

were springly shown. Mr. F. SANDER had a bright pinkish-rose double form, large and full, named Fred. Sander, the fringed petals gathered in, and given names (Award of Merit); and Messrs. JAMES CARTER & Co. had a number of seedling single and double varieties.

CALADIUMS

These showy and useful decorative stove plants were exhibited grandly, and in colour they surpassed very many of the flowers. Messrs. JOHN LAING & SONS, had exhibited a limited collection of the best quality; and Mr. F. SANDER showed two new varieties of the narrow leafed type.

Messrs. JERRY'S exhibit included a rare lot of novelties, of which the six seedling varieties known as Peol's Diamond Jubilee set were well represented. One of these we have reproduced (see page 352). Peol, a dwarf, belongs to the dwarf-growing section, being only about 6 or 8 inches in height. The leaves are about 4 inches wide and 6 inches long; they are bright rose in colour, with carmine veins, and are very pretty suffused with green at the margins. Our illustration shows four plants grouped in a basket.

Mr. W. H. CUMMINGS has a strong, pale pink leaf, having darker coloured veins, and green margin. Duchess of Teck is a very distinct variety of moderate habit, with milky white leaves, having a reddish spot at the summit of the petiole, and occasionally upon the veins. Henry DISSEN has pale green leaves, dotted with irregular blotches of moderate habit, being rather dwarf. Mrs. JAO. PEEL is another Jubilee variety of dwarf habit, having carmine or red leaves, occasionally splashed with green, with darker veins, and a slight narrow margin of green. We noticed also MANA DUBAI, a very pretty variety. There was a fine plant of ASSAGNY, a bizarre-looking variety, that was certified by Messrs. Peed & Sons at this show two years ago. Baron ADOLPHE DE ROTHSCHILD was represented by a good-sized plant, with numerous, large, roundish leaves of brilliant colour. Roncaudor was finely shown in the plant illustrated by fig. 124 in Supplement. It is a distinct variety, with large leaves, dark green veining, which towards the tip of the leaf becomes black. The interspaces are rosy-red, and the surface of the leaves is very or undulating, and glossy. Habitat moderate. Ori-banane, a brilliant red-coloured variety, and green margin, being of strong habit, is an exceptionally fine one for grouping; its effect is very telling. Mrs. Harry Veitch and President de la Deuyevaine were both noticed in fine condition. Rose Laing was exceptionally good in point of colour. Silver Cloud, and several other varieties, sent out by Messrs. J. VEITCH & SONS last season, like all of the plants from the Rompall Park Nurseries, were unusually well-coloured. Silver Cloud as shown in the group, was silvery-white, and rather freely and occasionally with a little green. Marquis F. D'Albertain, a green leaf with white centre, marked with rose; JAO. R. BOX and Madame MITJANA figured as large plants in the back row. The plants in this group were staged as thinly as space would permit, and each specimen being fitted with Ferns, was effective.

Messrs. JNO. WATERER & SONS, Forest Hill, S.E., contributed a magnificent group of Caladiums, directly facing the Orchids, and beautiful though the latter appeared, the Caladiums created a surpassing display of colour, which, for the moment at any rate, engaged the visitor's attention. Never before Caladiums were shown in better ordered specimens from the Forest Hill Nurseries. The plants included a number of plants in 12 and 14-inch pots of established varieties, such as candidum, which is an excellent variety for lightening the effect of a group, being white in the leaf excepting the very pretty veining; also Triumph de Comte, the largest specimen in the whole group; and a number of new varieties, including Rose, very fine; Baron Adolphe Rothschild, beautiful plant; E. C. Dablie, a distinct variety with different shades of rose and green marvellously mixed upon the surface of the leaf; and Charlemagne. Lesser plants of equally effective varieties, some of them being rather more rare than the preceding, including E. White, Louis Van der Meer, Julia Goldend, Countesse de Bresse, Mrs. Harry Veitch, Botafogo, a distinct and exceedingly pretty variety, bright red in centre of leaf, irregularly running into a broozy-green margin; Rose Laing, B. Duchesse, new and very pretty; Dona Carmen Macedo, Bona, Comte de Valenciennes, a very fine variety, with capital self-coloured variety, of effective shade of red, and others. Then there were nearer the front of the group such excellent and few varieties as Alexander III., represented by a plant carrying four leaves, two of which were of considerable size and wonderful colour. It will take a large group on the most judiciously selected and raised, and the broozy-green margin and slight markings of same colour heighten its effect; Ladus, Princess Olga, Ylva Formosa, La Nain Rouge, Michel Buchner, Golden Queen, Silver Cloud, F. Cooper, JAO. LAING, and others.

Facing the Orchids upon the opposite side, and placed immediately betwixt Mr. TRENSE's dazzling Roses, and Messrs. JERRY'S inviting ferns, the group of Caladiums exhibited by Messrs. JAMES VEITCH & SONS, Royal Exotic Nursery, Chelsea, was one of first-rate merit. Most of the plants were afforded sufficient space for individual effectiveness, and a carpet of Maidenhair Ferns served to sufficiently furnish the interspaces. A magnificent plant of Madame JAO. BOX in the centre of the front row, and a distinct appearance, and supported with excellent specimens of George Berger, Gaspard Creyer, Alice van Geert, silver-coloured with green markings; Mrs. Harry Veitch candidum, Baron Adolphe de Rothschild, the back of the group had an imposing appearance. The dwarf-habited Princess Royal, deep rose and green, the fringed-leafed Peol, and also a valuable one, and of Wales, Reine de Danemarck, and Silver Cloud, one of the set Messrs. VEITCH sent out last year, and a seedling raised by the late Mr. Bause, were all of good colour, and large in leaf; Mons. Léon SAY, a distinct shade of colour; La Lorraine, exquisite; Leonard Bause, dwarf; and Princess of Teck, a very distinct one. Lady Stafford Northcote, amongst the novelties for next spring, has a handsome self-coloured red leaf, and will make a sterling addition. Avilona, equally new, but of different colour, is also good. Mrs. McLeod, another novelty, apparently of moderate habit, is also a valuable one, and was recommended an Award of Merit similarly to Lady Stafford Northcote. Her Majesty, and exquisite, and a few other of the newer varieties adorned the front of the group, in addition to such dwarf varieties as Chelsea Gem, Duke of York, Barchess Schroeder, and Le Nain Rouge.

At the corner of No. 4 tent was furnished with a capital exhibit of Caladiums from an amateur, PASTIA RALLI, Esq., Ashstead Park, Epsom, Surrey (gt., Mr. G. Hunt). This collection, smaller when compared with the trade displays, included such new kinds as Silver Cloud, Madame Mitjana, Duchess of Fife, Assagny, and others, as from Adolphe de Rothschild, Madame JAO. BOX, Mrs. Harry Veitch, Sir William Brouncker, B. S. Williams, Marquis of Camden, &c. The plants were well grown, and creditable.

CANNAS

Messrs. H. CANNELL & SONS had a group of glorious Cannas staged contiguous to their Gloxinias. This included such varieties as Austria, a magnificent yellow flower of large proportions; and Jubilee Croton (Croz), a self-coloured flower, originally described by the raiser as Chestnut red, but better described as salmon-red; Progression, Comte de Bouchaud, Duchess of York, all spotted red upon a yellow ground; Queen Charlotte, red, with yellow margins; Souvenir d'Antoine Crozy, bright scarlet, with small yellow margins; Prince of Wales, scarlet, of the very fine in colour; John, very large flower, primrose yellow and red, very fine; Pearson & Co., P. J. Berkans, Golden Star, and others.

BEGONIAS

Though this show may be said to be rather too early for tuberous Begonias to be exhibited in the perfect condition they acquire in summer, owing to the great efforts put forth by those who manage them, especially, there is always a gladden display, and the present show was by no means an exception in this respect.

The Begonias from Messrs. J. LAING & SONS, Forest Hill, London, S.E., were finely grown plants, with good foliage and large blossoms of good substance. They were arranged in a most unobtrusive and pleasing manner, and were well exposed, in addition to the Isoplepis that was used as a margin. An excellent rosy pink flowered double variety named Duchess of Marlborough we reproduce in fig. 126. It has a good and erect habit, and the flowers are of very perfect Camellia form.

A long, narrow collection of double and single-flowered tuberous Begonias was exhibited on the side-stage in Tent No. 2 by Mr. JNO. R. BOX, West Wickham and Croydon. These made an excellent display, and the plants were good in habit, and carried numerous flowers of capital quality. Few of them were of the very fine in colour; but, of considerable value; Queen of Wartenburg, also double, but of rather different shape, and being much paler in the same colour as the preceding one; Princess of York, lighter shade still; also, double Queen of Queens, rich apricot—very fine indeed. The names of the singles need not appear, as they are flowers well known, and well-dressed distinct and good colours of commendable substance.

Messrs. H. CANNELL & SONS, Swanley, Kent, had a splendid group of Begonias, the double-flowered varieties strongly predominating. The habit of the strains is decidedly good, the colours of the flowers very bright, and their size and substance all that could be wished for. Such varieties as Lady Bigge, Mrs. W. B. Miller (crimson), Lady Gertrude, Lord Sherborne, Miss Brooke Firman, Leopold de Rothschild, R. E. Parsons pink, and many others, are of exquisite description.

Mr. H. JONES, Beyerly Nursery, Lewisham, S.E., had a large group of tuberous-stemmed Begonias, including double and single-flowered varieties, relieved by interspersed Ferns and Cosmos Palms. The group, however, was rather too closely arranged, probably owing to the necessary culti-

ment of space. Some of the best double-flowered varieties were Orion, scarlet; H. J. Jones, very large, intense scarlet; Walter & Finch, Miss Lady Felt, white; Beauty of Belgrave, pink; La France, pink; and other single-flowered kinds of merit included Primrose Queen, yellow; Daisy Wright, very pretty, white edged with scarlet; Firely, deep crimson; Lord Byron, scarlet, with white centre; Beyerly, very large, buff &c.

Mr. THOMAS S. WARE, of the Hale Farm Nurseries, near Tottenham, made a display of Tuberous Begonias on one of the side stages in No. 3 Tent. Like most of the collections of these plants, the one from Tottenham possessed great merit. We noticed Jubilee Beauty, rosy scarlet, with white centre; Prince of Wales, scarlet, with small white centre; Charlieb; Pride of Kent, bright rose, of large size; Samuel Pope, a pretty edged variety like a Ficoete, but much larger; Queen Victoria, soft pink; Jubilee Queen, double white, of good Camellia shape; Robert Lawford, scarlet; Rosebud, pretty bloom, of delicate rose, as some of the best.

Fibrous-rooted Begonias were splendidly exhibited by Messrs. STURTON & SONS, Reading, in beds in the open, in which the plants were plunged. These represent a great variety of colour, and include Sutton's Reading Snowflakes, pure white, and Crimsom Gem. Between these there is almost every gradation of colour. Coral Green and Duchess of Edinburgh are exceptionally pretty ones. The plants had been raised from seed five months previously. In fig. 130 some of these plants are illustrated.

STREPTOCARPUS

The best display of Streptocarpus was a superb group staged by Messrs. J. VEITCH & SONS, Chelsea, in the centre of the tent. These were magnificent plants were arranged in groups according to colour, and represented the different strains that have been obtained by the Chelsea firm. Some of these are pure white, others white with purple darkening on throat, some almost scarlet, others just as near being purple, and therefore modifications in every conceivable way in point of markings and colour. Then there were the 8 graft varieties, which produce numerous smaller flowers upon a spike, being exceedingly floriferous, some bearing fifty buds and blossoms. The colours in this section are exceptionally pleasing. The foliage is rather large, but otherwise the strains are of great value. It is a pity that the section has so far failed to produce seed, and must be propagated by division. The pulchellus hybrids grow taller, throwing their beautiful flowers a foot or more above the pot.

HYDROCACTUS

Messrs. J. VEITCH & SONS, Royal Exotic Nursery, Chelsea, made a bright and excellent display with their hybrid Hydrocactus, a section of Cactaceae plants that, owing to Messrs. Veitch, are now becoming more popular. They are exceedingly showy flowering plants, and though the flowers last but a few days, the tints of colour are exquisite. An Award of Merit was gained by Mrs. J. Veitch's rosy pink, large and pretty flower; also by Syren, with flower of rose, shaded salmon, deep rose at centre. Brilliant is a bright scarlet variety, and Ovis very pale pink, uncommonly large, handsome flower. Thalia is also very fine, and Esquisse, salmon-scarlet; Agatha, Cooper, white; Delicata, rosy pink; Fedia, bright yellow; Eclair, deep crimson; Rose Perfection, and others among the best shown.

RHOIODENDRONS

Messrs. JNO. WATERER & SONS, Ltd., Bagshot, Surrey, had a group of hardy Rhododendrons in flower at the end of the Orchid-table in the large tent. The plants were about 2 feet high, bushy, and capitally flowered. The varieties were named ones, and included some splendid colours and tints. The largest flower was one named Pink Pearl, of delicate flesh colour, and deep rose-coloured stamens. J. H. Agnew, Star of Windsor, Kate Waterer, rose-coloured; B. W. Currie, and Marchioness of Lansdowne were all good.

GLOXINIAS

There were several collections of these plants exhibited, the largest and finest being from Messrs. STURTON & SONS, Reading, who filled more than half the central table in No. 3 tent with plants representing their best and selected types. Her Majesty, well known as the most perfect white-flowered Gloxinia yet raised; Duke of York, white; Duchess of Bessborough, rich purple; Empress of India also rich purple; Reading Scarlet, an exceedingly bright, almost dazzling colour were represented in numerous instances; Azure Iliac also represents a most lovely-tinted strain, of exquisite character. Sutton's spotted hybrids, which flower rather late than most of the other varieties, were represented by a later than the rest, each of which were spotted or marked in a pleasing and delicate manner. The collection created an unusual effect, and the individual plants were excellent in habit, and had been capitally cultivated. We shall give an illustration next week.

Messrs. J. CARTER & Co.'s Gloxinias were staged on a central table in Tent 2, and formed part of a very large exhibit of various plants in flower. The Gloxinias represented the firm's strain, which is one of first-class merit and selection.

A small group of Gloxinias was staged by Messrs. J. PENN & SONS, Rompall Park Nurseries, Norwood Road, London, S.E., including a number of the most valuable varieties, with rather small flowers; also JAO. PEEL, a rose coloured variety with white margin; Duke of York, white and heliotype colour, very pretty; Mrs. JAO. PEEL, with white and deep margin of pinkish-lilac; Aigburth Crimsom, F. Firfield, and others.

Messrs. J. VETCH & SONS, LTD., exhibited a small group of Gloxinias, including excellent and well-flowered plants, the habit of them as shown being specially meritorious. The varieties included Orion, white; La Belle, white excepting faint rose markings at the divisions of the tube at apex;

Messrs. H. CANNELL & SONS, Swanley, Kent, exhibited a group of Gloxinias between their fine Begonias and beautiful Camas. In the Gloxinias one of the very best varieties was Prince of Wales, the largest plant of which we reproduce in fig. 132 (see Supplement). It is larger than Beacon, but

FIG. 132.—ENKYANTHUS JAPONICUS; HARDY WHITE-FLOWERED SHRUB.
(Exhibited by Messrs. Vetch & Sons at the Temple Show.)

Cordelia, a curiously spotted one; Cicely, with spotted throat and narrow pale margin, the rest of surface being purple; Duchess of Teck, a Gesnera-like flower of varying degree of crimson; Janet, spotted with blue crown; and Sunbeam, a very bright one.

A few plants of Gloxinias were also staged by Mr. J. S. R. Box, West Wickham and Croydon. These plants were interspersed with a few Ferns.

hardly so dark in colour. Petunia, white, with pale lilac or herbaceous margin, is a good variety; and William Marshall, which is pretty generally known. Dorothy Dean, one of the darker purples, with pale margin; and Agan, with white base of throat, white margin, and other parts red, are both good. Lieut. Colonel Fishwick, Verona, a white; Harcourt, a curiously spotted flower; and Miss Cannell, white, with marking of purple, were also noticed.

FERNS.

As regarded the number of varieties, their interest, and the skill shown in their cultivation, the collection shown by Messrs. W. & J. BIRKENHEAD, Sade, Manchester, was an especially good one. The larger plants consisted, amongst others, of Adiantum variciliatum, A. cultratum, A. cucullatum elegans, A. decurans, A. Hodgkinsoni, a plant elegant in habit, with slightly divided pinnae; A. cucullatum var. O'Brieni, A. speciosum, A. Williamsi. The Golden Maidenhair, A. aethiopicum aureum, a variety of a sparse habit, yellowish, green coloured pinnae, and a black rachis, from the Orange Free State. The middle row of the group, and the taller plants, contained Ad. pelatum, Davallia filiformis, Streptopteris germanica, Balanidium ciliata, Osmunda Claytoniana, and handsome species of tall, nearly vertical habit of growth; Athyrium gemmatum, a much crisped form, A. f. plumosum elegans. Orate among small examples were Polystichum angulare, Ornithopteris among small examples, having very fine dense fronds, plumosum distichotum tenax, having very fine dense fronds, with overlapping pinnae and substylis-n. Athyrium Frizelle coronare, much frizzled; A. f. f. apiculare; A. f. f. grandiceps; A. Giraldoni cristatum, a striking variety, with fasciated subdivision of the fronds; A. holothrix, Osmunda regalis cristata, Gymnogramma Willdenowii, densely powdered; G. Peruviana argophylla, Cheilanthes farinosa, Alaphila pruinata, a Fern with a hard frond of a much-divided type, and slender, narrow pinnae, which are dentated on one edge only; Adiantum capillus veneris elegantissimum; A. Legrandii a much-fasciated form, growing about 9 inches high, probably a variety of A. gracillimum; Gymnogramma cheroxyphylla, an annual species; Ad. regina, Felles Druryi, a very dwarf close habit Fern from California, blue-green in colour, and wedge-shaped; P. ornithopteris, dwarf, with finely divided fronds; P. andromedifolia, with graceful, pretty fronds, light green in tint, and rachis light brown and smooth; Gymnogramma Muelleri, very distinct, with pinnae of a dark green colour, having many short, white hairs on the upper surface; Lomaria aspera, a remarkable Fern, with a long-winged and serrated rachis, at the end of which are six to eight similarly serrated strap-like fronds. The habit is pendulous. Osmunda speciosa corymbifera is a pretty, slightly crested Fern of light green colour. Asplenium austradicum is a sort of bird's nest Fern with undivided frond and black midrib.

Mr. H. B. MAY put together a large exhibit of Ferns in examples much larger than his more distant rivals, Messrs. Birkenhead, who are handicapped by heavy railway charges, and do not care to show large plants so far from home. The choicer and smaller examples in Mr. May's group included Blechnum gracile, Doryopteris nobilis, with a fine dark green digitate frond; Gymnogramma Mayi, a densely powdered silver Fern; G. grandiceps superba, a pretty-fasciated Gold Fern; Cheilanthes diandra longipinna, an elegant variety; G. rupestris glaucescens; Paris regina, white and green fronds; P. Victoria, similar to the last Asplenium Mayi, a striking species of a dark green colour, with leathery pinnae, set on short fronds; Davallia Mariesii maxima, and also the type; numerous Adiantums; Lygodium scandens and L. japonicum, Decussately apifolia, a handsome, robust growing species; Pteropeltis lyopodioides, Osmunda cinnamomea, Platycerium aethiopicum, &c. The group was set up without rowding, and the best things were well brought out.

CUT FLOWERS.

Collections of mixed cut flowers were numerous and varied in character, and it was satisfactory to note that less of an inferior character than usual was staged, though a little more weeding out of cut flowers might still be followed without loss.

Messrs. W. PAUL & SONS, Waltham Cross, had bunches of foliage of what have been termed pictorial trees and shrubs, and a foreground of boxes of cut Rhododendrons, chief among them, Mrs. Milner, Charles Buckets, and John Russell, Old Park, Lord Palmerston, Lady Berthelme, Mr. H. H. Hunnewell, Michael Waterer, Atro-sanguineum and Draymanum.

Messrs. BARR & SONS, King Street, Covent Garden, furnished a great length of falling. Among their subjects were varieties of Papaver orientale, Iris germanica in variety and several species; bunches of flowering shrubs and perennials, Tulips and Narcissi being prominent; and also a bank of rockwork suitably planted. This made an effective exhibit, but several weak bunches were in the collection; such a display at such an exhibition should consist only of plants of acknowledged value and novelty. This remark applies equally to other collections.

Messrs. GEO. JACKMAN & SONS, Woking, had a collection of hardy cut flowers, which included Oriental Poppies, various Pyrethrums, a batch of Fritillaria luteola, Phlox canadensis, Dodecatheons, &c.

Mr. B. LABBANS, nurseryman, Shirley, Southampton, had a good collection of similar character, and here, as elsewhere, the big Oriental Poppies were very striking; there were fine bunches of Helianthus sanguinea, the deep blue Anemone hardieri, the pale pink perpetual-flowing Pink diamant, the true form of Delphinium Borlowi, deep purple with a white centre; Senecio doronicum, various Iris, &c.

Messrs. PAUL & SONS, Old Nurseries, Chelsea, had cut blooms of perennial Poppies, forms of Liatris polyphylla, Helianthus Silver Queen, a fine variety of a silvery-scented, and some bunches of the newer Lilies, single and double, such as Souvenir de la President Carnot, Dutch, Madame Lemoine, Alba grandiflora, Alphonse Lavallee, Souvenir de L. Spath, and Shilstone, bluish blue of pure shape.

Prize List.

Cuts. Messrs. Low, Clapton, for a group of Orchids; Caladiums, Cannas, &c.; Messrs. Wm. Paul & Son, Waltham Cross, for Carnations, Rhododendrons, &c.; Messrs. Fair & Sons, Cannan, and Alpine Plants; Messrs. Charlesworth & Co., London, for Orchids; Messrs. Barr & Son, Covent Garden, for Herbaceous Plants; Messrs. Mackenzie & Co., for Alpine and Hardy Plants; Messrs. Wallace & Co., Colchester, for Lilies, Irises, &c.; Horticulture International, Brussels, for Orchids; Messrs. Dobbie & Co., Rothsay, for Pinks, Fancies, &c.; Sir J. W. Pease, Bart., Hutton, for Fruit; Mrs. Wingfield, Appleby, for Potatoes and Vegetables; Sir W. G. Pearce, Bart., Huccogford, for Fruit; Messrs. Sander & Co., St. Albans, for New and Rare Plants; Messrs. Carter & Co., Holborn, for a group of Caladiums, Begonias, &c.; Messrs. Turner, Slough, for Irises, &c.; Messrs. Laing, Forest Hill, for a Group of Caladiums, Begonias, &c.; Messrs. Jones & Sons, Shrewsbury, for Decorations; Messrs. Todd, Swanley, for Begonias, Calceolarias, and Flowering Plants.

GOLD MEDAL. Messrs. James Veitch & Sons, Chelsea, for hardy plants, shrubs, Calceolarias, Begonias, Scrotopocrans, Vegetables, &c.; Messrs. de Rothschild, Greenwich, for Fruit trees in pots and Myrtles, &c.; Messrs. Rivers, Sawbridge-wood, for fruit trees in pots; Messrs. Barr & Son, & Silray, Sheffield, for hardy plants; Mr. Geo. Monat, Canterbury, for Carnations; Baron de Selys, The Dell, Stour, for Orchids.

Mr. J. W. Trevor, Lew- 1897, President of the Society, would have received a Gold Medal had his plants been for competition.

SILVER-GILT KNIGHTIAN MEDAL. Messrs. Hurrend & Co., Maidstone, for fruit trees in pots, and Apples.

SILVER GILT FLORA. Messrs. May, Edmonton, for Ferns, &c.; Messrs. Frothingham, Chelsea, for Carnations; Messrs. Cripps & Son, Tumbriage Wells, for Maples; Messrs. Wills & Sagar, Kingston Crescent, South Kensington, for Palms, &c.; Messrs. Hurrend, Waltham Cross, for Roses; Messrs. Kelway, Langport, for Peonies, &c.; Mr. Philipp, Reading, for decorations; Messrs. Moyses Stevens, 146, Victoria Street, S.W., for decoration; Mrs. W. Grece, for decoration for table decoration; Messrs. Perkins, Coventry, for decorations; Miss M. Foden, for decorations; Sir P. Wigan, Bart., East Sheen,

Joint Committee.

FIRST-CLASS CERTIFICATE. To Davallia hirta, from Messrs. P. Sander & Co., St. Albans.

Award of Merit. To Clematis of Albany, from Messrs. G. Jackman & Son, Woking; to Clematis Marcel Moking, from Mr. Moser, Vercelles; to Clematis Argentea, from Mrs. P. Madane Moser, from Mr. Moser, Vercelles; to Clematis, from Messrs. F. Sander & Co.; to Ficus radiata, from Mrs. J. G. Bull, Chelsea; to Iris bipina, from Messrs. R. Wallace & Co., Colchester; to Phyllocactus, from Messrs. J. Veitch & Sons, Chelsea; to P. Sprucei, from Messrs. J. Veitch & Sons, Chelsea; to P. Freya, from Messrs. J. Veitch & Sons,

Chelsea; to A. r. fl. p. Ribera, from Messrs. J. Veitch & Sons, Chelsea; to Caladium Mrs. M. Sander, from Messrs. J. Veitch & Sons, Chelsea; to C. Italy Stafford Northcote, from Messrs. J. Veitch & Sons, Chelsea; to Pyrethrum Wilson Barrett, from Messrs. Kelway & Son, Langport; to Bonnier Carnation Articus, from Martin R. Smith, Esq., Hayes; to Croton Her Majesty, from Messrs. J. Veitch & Sons, Sheffield; to Carina Comte de Bonchard, from Messrs. H. G. Bull, Chelsea; to C. C. de B., from Messrs. Paul & Son, Chesham; to Begonia Diamond Jubilee, from Mr. J. R. Cox, Crayke; to M. Queen of Queens, from Mr. Box.

Botanical Certificate. To Arisaema Bakeriana, from Messrs. P. Sander & Co.

Awards of the Orchid Committee.

FIRST-CLASS CERTIFICATE. Odontoglossum crispum "Staught," from R. Brown White, Esq., Ardriachro, Perth; to Odontoglossum crispum, from R. J. Measures, Esq., Camberwell; Lecho, from Messrs. Chartersworth & Co., Heaton, Bradford; Lecho purpurata Answorthiana, from E. Ashworth, Esq., Huddersfield; Odontoglossum spectrum aureum, from W. Thompson, Esq., Walton Grange, Stone; Lecho Catleya Tynter-Belkense, from Law Schofield, Esq., Rawcliffe; Odontoglossum crispum Queen Victoria, from Messrs. High Low & Co., London; Lecho Schilleriana, Hardy a var., from F. Hady, Esq., Tyntersfield.

Award of Merit. Odontoglossum Richard Ashworth, Esq., Ashlands, Newchurch; Arocaechius San-

derianus, from Messrs. P. Sander & Co., St. Albans; Odontoglossum crispum Annie, from W. Thompson, Esq., Stone, Staffs.; Odontoglossum excellens Thompson, from W. Thompson, Esq., Stone, Staffs.; Lecho bipina, from A. Featherston, Esq., Vine House, Haslingden; Cattleya Mendocino, from Messrs. W. Lewis & Co., Southgate; Odontoglossum Paeffleri, from Messrs. Linden, Brussels; Cattleya Messia Empress Queen, from Messrs. Linden, Brussels; Cattleya crispum Paeffleri, from Messrs. Linden, Brussels; Cattleya Mendocino var., from Baron Schroder, The Dell, Staines; Cypripedium calceolatum, from Thos. Spatter, Macclesfield.

Botanical Certificate. To Clematis of Albany, from species from Borneo, from High Low & Co., Clapton.

Fruit and Vegetable Committee.

FIRST-CLASS CERTIFICATE. To Tomato Golden Jubilee, from Mr. O. Thomas, Royal Gardens, Frogmore.

Award of Merit. To Melon Diamond Jubilee, &c. between an unnamed seedling, from Messrs. C. C. Herrin, Frognote, Maidhead.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

May 20.—The first annual meeting for adjudging upon the merits of the orchid show was held on the above date in the large room of the Corn Exchange. This is an admirable room for the purpose, being 60 feet by 26 feet, and very lofty and well lighted.

There was an admirable display of select and well-cultivated plants, the finest collection coming from A. Warburton, Esq. (Mr. T. Lothosen, gr.), Vice-Hon. Haslingden, worthy, indeed, of a large Silver Medal, but not put up either individually or collectively for competition. Other growers whose names I will not put up for awards, making together an aggregate of brilliant displays, satisfied beyond expectation of the organisers of the movement. There are now fifty members, and the prospect of increase is good.

The following were the members of the Orchid Committee present:—WM THOMPSON, Walton Grange (Chairman); G. S. Ball, (Treasurer), Wm. A. Cox, Esq. (Hon. Secretary); A. Warburton, B. Greenwood, W. Ruppert, W. Balton, P. Weathers, John Cowan, Wm. Steven, James Anderson.

Mr. Thompson showed Cypripedium Rothschildianum (First-class Certificate), with four large flowers on the stem, the most beautiful and having the inferior sepal about as large as the dorsal, scaping in this way Mr. Cookson's well-known variety Cattleya intermedia (First-class Certificate). This was the gem of the exhibits, snow-white in all its parts, and of great substance—a large flower, too. Odontoglossum spectrum aureum (First-class Certificate), remarkable in its way, the form good, the semi-blossoms on a yellowish ground, marking it as a novelty among the "aurea" flowered tooth-tongued Odontoglossum. Odontoglossum crispum "Annie" (First-class Certificate). This is one of the choicest of the richly-sepal'd and blotched varieties, with a beautiful, but a little hoarse, color to make up; the coloring, however, was superb. Odontoglossum excellens Thompsonianum (First-class Certificate). This is undoubtedly the richest and best form up to the present time in commerce, bearing all that have gone before it, in respect to form, rich colouring of yellow and prominent blotches.

G. S. BALL, Esq., Ashford, Windoad (gr. Mr. A. Hay), submitted, out of his general lot exhibited, the following plants:—Lycaste Skinneri alba (First-class Certificate), having three fully-expanded flowers of wax-like substance, white as possible, with only the tongue of the lip lemon, shading towards the base of the labellum palely yellow; Cypripedium callosum Sanderi (First-class Certificate) set in a front rank plant, which will take some beating; Cattleya Skinneri alba (Award of Merit), a fine, clean, green piece, white in the segments, but the blades of their lips showing a slight tinge of yellow.

EDWARD ASHWORTH, Esq., The Ashlands, Newchurch (Mr. Pidsley, gr.), sent a plant nicely in flower of Cattleya, under the name of Gaskelliana alba, which the jury of experts unanimously relegated to Mossie Wagner, and gave it an Award of Merit as such; the flower was large, with a grand centre lip, not so heavily charged with lemon blotch as many forms of Wagneri.

Geo. LAW-SCHOFIELD, Esq., New Hall Hey, Rawtinstall (Mr. E. Schill, gr.), sent Cattleya Skinneri alba (Award of Merit). The colour of this is an exceedingly pleasing shining white, with a centre lip, with a yellow to a magenta on the basal blotch pure white, making a telling individual flower. The grandest group of Lecho purpurata in variety, from whitish up through the intermediate shades, the deep

wooden lips—notting finer than Imperator—was by Mr. W. ARBUTHNOT, who brought out Cattleya Mossie, the well-flooding Bessie's variegata, the showy yellow ground Ogdium Marshallianum. This table filled about one-half the length of the hall.

Messrs. JOHN COWAN & Co. sent also a large assortment, containing some very good Lecho purpurata. Mr. W. SIMONDS, Esq., 18, Finsbury Square (gr. Mr. Skinner), exhibited two beautifully-grown and flowered plants of Deudorobium Janesianum, which well merited a Cultural Certificate; there were more than a score of flowers in each set negro-liriate bulb, covered with leaves, too.

Mr. G. GREENWOOD, Esq., Highfield House, Haslingden (gr. Mr. Spurr), sent a collection of select Lecho and Cattleyas.

FRED SKINNER, Esq., Hopcild, Didsbury, submitted his spotted form of crispum.

JAMES LEEMANN, Esq., West Bank House, Heaton Mersey (gr. Mr. Edges), showed an extra fine form of Cattleya Schilleriana, much larger and brighter in every way than the type, but the committee did not see the plant passed it over.

A. HEISE, Esq., Birchfield, Rushmore (gr. Mr. Craig), had an extra fine form of Odontoglossum Andersonianum, running more into the crispum than usual, as well as a couple of forms of Od. crispum. WM. BOLTON, Esq., Wilderspool, Manchester, sent out Cattleya Schilleriana, the best of them being a well-formed richly adorned Cattleya Mendeli Thos. RAY, Esq., Craigclogh, Perth, sent a collection of varied cut flowers. DENCAN GIMMOES, Esq., High-bury, Sheffield (Mr. Wm. Day, gr.), showed several good varieties, the best of them being Cattleya Mendeli "Queen of the West" and "High-bury Queen" by J. Dutton, Esq., Sunamere, Dumfriesshire, sent an excellent spike of a good variety of Cattleya Mossie.

BATH AND WEST OF ENGLAND AGRICULTURAL.

A horticultural exhibition in connection with the above is yearly held. The site this year was Southampton Common, a place in every way adapted for the purpose. The usual system of issuing a schedule of prizes of the orthodox kind is not the practice with this Society; on the contrary, a sum of money is set apart yearly for horticulture, which Mr. H. Fowler distributes according to the merits of the various exhibits. A spacious marquee covers the entire exhibition, and as plants in pots and cut flowers only are shown, the effect was excellent. A row of Palm-trees down the middle, forming a handsome background for the collection of plants, &c.

Mr. B. LAHAMM, nurseryman, Shirley, Southampton, arranged a fine collection of hardy flowers, both growing and out, to face the entrance to the marquee, groups of Iris, Pyrethrum roseum in variety, Pseodius, Heuchera sanguinea, and many examples of gorgeously-flowered Cannas. Messrs. W. CUTTAVEN & Son, of Highgate Nurseries, London, contributed a group of admirable Carnations. Mr. E. WILLS, nurseryman, Winchester Road, Shirley, staged a marvellous group of miscellaneous plants. Miss TROTT, Esq. (gr. Mr. W. Peel), staged a number of fine hardy Azaleas, stag and greenhouse plants—a pleasing arrangement of one kind, and having the effect of a fine display. Messrs. PAUL & Son, The Old Nurseries, Chesham, showed a beautiful lot of cut flowers of hardy plants, and of Lilacs and Rhododendrons in variety.

Messrs. BARR & Sons, King Street, Covent Garden W.C., sent from their Long Ditton nurseries a collection of cut flowers of hardy plants.

Messrs. J. LAING & Sons, Forest Hill, S.E., staged tuberos Begonias, Gloxinias, Crotons, and Palms, admirably grown, and possessing much that was of interest to the visitors.

From Mr. N. J. GOSWORTHY, Emsworth, came well-flowered Platanus in variety, and affording much desirable brightness to the tent.

Messrs. G. COOLING & Sons, Bath, showed cut blooms of Tea Roses, Briars, and other Roses. Mr. W. H. ROGERS, Red Lodge Nurseries, Southampton, arranged a large group of Rhododendrons, and a number of shrubs grown in pots, which came in for much admiration.

Messrs. E. HELLER & Son, Winchester, showed a choice collection of Acers as pot plants, and other hardy shrubs of note.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

The Fifty-ninth Anniversary Festival took place at the Hotel Metropole on the 26th inst., the Rt. Hon. Lord Rothschild presiding, supported by Lord Wandsworth, Sir Trevor Lawrence, Bt., Mr. H. J. VEITCH, the treasurer, and other members of a company numbering some 150 persons. After proposing the usual loyal toasts, the CHAIRMAN said: The Society was almost contemporaneous with the commencement of the reign of Her Majesty, and those among them who were old enough to cast their memories back to the time of the accession of the Queen, could realize that during the last 70 years B-tany, arid-architecture, and horticulture had made tremendous strides. The noble Water Lily, the Victoria Regia, and that lovely Orchid named in honour of the Princess of Wales, had come to them during the last 70 years. Our descendants sixty years hence would not be able to glean over the production of new hybrids and

the introduction of new subjects that would also make that year glorious in the annals of horticulture. In looking back over the progress made by The Gardeners' Royal Benevolent Institution since its formation, he was sure the retrospect would bring to its supporters a sense of great pride and self-satisfaction.

Mr. H. J. VERRILL, the Treasurer, responded by summarising the progress of the Society. They had elected this year 29 pensioners, the largest number elected at one time, but in 1851 when the Queen became the patron of it, there were 35 pensioners; in 1857 the number is 161. In 1851 there were 15 candidates, and two were elected; the highest number of votes was 150. In 1857 there were 49 applicants, of which number 29 were elected; the highest number of votes recorded was 3700. In 1851 the sum of £512 was paid to pensioners; in 1857, £3000. The income from subscriptions in 1851 was £748; in 1856, £3833. In 1851 the sum of £2250 was invested; in 1857 it is £29,700. If the real test of the value of an institution is the work it has done, then their supporters may certainly justifiably pride. The Committee has decided that by way of celebrating the Diamond Jubilee of Her Majesty, the sum of £5 should be given to each of the unsuccessful applicants at the last election. They had also decided to form a Victorian Era Fund of £5,000, the money to be raised and the sum derived therefrom to be given to candidates in necessitous circumstances prior to election. As £500 is the amount aimed at for this year, the list would be kept open till the end of the year. Mr. Veitch concluded by making a feeling reference to the deaths of Mr. James Webber and Dr. Hoag, the latter a trustee for many years, and said that the Hon. Walter Rothschild had been appointed in his stead. The Secretary, Mr. G. J. Ingram, announced that the sum subscribed up to that evening was £5750.

Obituary.

THE REV. E. N. POCHIN.—This well-known Russian, the Vicar of Barkby, near Leicester, died at the Vicarage on the 14th inst. at the age of seventy years. It was while he was Rector of Sibehy, near Leicester, from 1863 to 1873, that he came to the fore as a cultivator and exhibitor of Roses, and he gave to this popular subject his special attention. But other subjects also interested him, among them the Sweet William, which he helped to improve, and l hardy flowers generally were his favourites. In 1873 he was appointed Rector of Barkby, where he died. Mr. Pochin was well known in horticultural circles at Leicester, and acted as one of the judges of florists' flowers, and especially of the Rose at the exhibitions held in the Abbey Park, and throughout the district. His presence at the Abbey Park shows was always doubly welcome for the sake of his happy and genial speech at the luncheon to the judges. He was an occasional contributor to the horticultural press, and in 1850 he contributed a paper to the *Rosarians' Annual*, demonstrating the advantage of taking buds for propagating purposes only from shoots producing the finest developed blooms. In his own immediate sphere of labour he was much esteemed; and his death much deplored.

NOTICES TO CORRESPONDENTS.

BEOON'S G. G. ONIUMS, &c.—A. E. K. The plants are not attacked by a fungus. Stagnant water at the roots is probably the cause. *G. M.*

BITTERNESS IN CUCUMBERS.—A. P. A common cause is the cooling of the hot-bed; anything that would check the growth might cause it, as, for instance, coldwinds.

BLACK CURRANT WITH DISEASED SHOOTS.—T. S. The buds are infested with Phylloxera ribs; a very minute mite capable of doing great injury to the Black Currants, and sometimes present in such immense numbers as to quite ruin the bushes. Examine the latter very carefully, and cut off every shoot on which these abnormally swollen buds are found, burning them forthwith. If the bushes are greatly and generally affected by the mite, they should be cut off at the ground-level and burnt, the spot where the stens stood being dressed thickly with gas-lime. As a remedy where a few bushes are attacked, use lime and sulphur, or the latter, and strong soft-soap-suds and pumice. Mr. Arthur Bull of Cottenham, Cambs, gives the following in Miss Ormerod's *Manual of Injurious Insects*:—"Use a dressing of two parts sulphur and three parts lime boiled together in water (2 lb. sulphur and 3 lb. lime, 3 gal. water), which is further diluted at the rate of 2 or 3 pints to a large pail of water. This is applied with a syringe to the

infested bushes; the effect is to keep the 'spider' down, and that little or no damage is done. It seems difficult to clear the garden altogether." Change of crop; skimming off the surface-soil with the old leaves, and charring it would do some good, taking care to collect the soil and leaves from round the collar of the bushes. The same or a very similar mite sometimes infests the Red Currant.

COARSE GRASS IN AN ORCHARD.—J. F. Constant mowing for a year or two will have the effect of making the grasses less coarse; and if horned stock be turned into it, the droppings should be scattered about, and not left as they are voided. If sheep can be penned on the land, and left on each piece almost as long as they can find anything to eat, it will tend to make a fine close sward of fine grasses.

CUCUMBER PLANTS.—H. J. G. Single-stemmed plants are readily obtained by training up a seedling or a rooted cutting to the desired height without pinching out the growing point of the stem before it has reached that height. If it be then stopped, several lateral shoots will form near the top, which can be trained radially and themselves be stopped when 2 feet of growth has been made, and so on till the trellis be covered with bine.

EPIDENDIUM.—H. K. When you say that your Epidendrum has the growth of *Xanodes* you do not mean to say that it is as small as in that section of Epidendrum, we suppose. The growth is doubtless larger, the fleshy leaves larger and of a bright green. It is the plant which has been known for many years as Epidendrum umbellatum.

GARDENIA.—F. G. S. Too deeply-potted. The brownish may be due to root-burning, or to deleterious paint, tar, &c., on the hot-water pipes. No fungus was present.

GRUBS.—W. F. D. *Veronica*. Those sent are the maggots of Daddy Long-legs, or Crane Fly (*Tipula clarea*). The flies are about throughout the summer, and they lay their eggs on damp grass and leafage near the soil, and these are very numerous. The fly frequents damp meadows, neglected herbage, and shady spots, and the herbage in such places should be mown and burnt; bush harrowing is, according to Miss Ormerod, a good plan to diminish a fly attack. Rooks, sea-gulls, and ducks devour the grubs greedily, and these latter birds might with advantage be penned on infested land, or on such as the females visit to lay their eggs. Land free from crops should be dug, ploughed, and harrowed, and left to the attention of the birds named. Deep cultivation is a good means of destroying the grubs, and also dressings of guano at the rate of 4 cwt. per acre. Rolling with a Crosskill roller at night does good, as then the grubs come out to feed, and many get killed. A dressing of Rape-cake, and the roller used early in the morning, have good results. Anything that will give the plants a good start is advantageous.

HANTHOUS STRAWBERRY NOT FRUITING.—T. J. Leyell. The Strawberry is in the wild state deciduous—that is, the male and female blossoms occur on different plants, the Hawthorn being "unimproved;" except in so far as cultivation gives a stronger plant and larger fruits, it is essential that you should plant males and females together to obtain fruit. You have the female flower-bearing plant. You may have varieties of Strawberries growing alongside or in the same garden, and the Hawthorn, and pollination may take place, but it is not succeeded by fertilisation, and no cross is effected. You must have the male Hawthorns, whose flowers expand in rather long succession, as do the female flowers. Get an assurance from your nurseryman that his plantation contains both in quantity, or obtain seed the produce of which is sure to consist of both sexes.

INSECTS ON CARNATION ROOTS.—W. W. The creatures eating into the roots of your Carnations are millipedes (Julus). They may have been introduced with manure since the lime-dressing to which you allude. You might try a further lime-dressing of nitrate of soda, or mustard-dross, which is recommended for wire-worm, &c. But it would be better to plant in fresh soil, and burn the old. Some prefer to think that the Julus follows up attacks made by something else in the first instance. *R. M. L.*

IRISH AND OTHER IVIES NOT THRIVING ON A SOUTH-WEST ASPECT.—A. F. Y. There must be some-

thing inimical to the plants in the soil, or the plants have not had time for full re-establishment, as we cannot believe that the aspect has anything at all to do with the failure of the plants. Look at the immense masses of Ivy on the ruins of say Pembroke, Corfe, Hurstmonceux Castles; that of Corfe being 90 feet high, and exposed to every wind that blows. Aspect can have nothing to do with it.

NAMES OF PLANTS.—Correspondents not answered in this issue are requested to be so good as to consult the following number.—W. G. *Moyes*. Blue flower, *Gentiana acaulis*; yellow one, *Berberis Darwinii*; the third, probably *Impatiens Raylei*. Send when in flower.—H. M. 1, *Pyrus Malus* var.; 2, *Crategeus coccinea*; 3, *Lonicera quiquefoliaris*; 4, *Lonicera tatarica* pulcherrima; *F. Herringtonii*. Catherine Mermet, one of the best climbing varieties.—J. L. *Matthiola tristis*.—*Rita*. *Ledum palustre*.—F. F. 1, *Ranunculus*, double-flowered; not recognised; 2, *Cytisus purpureus*.—H. R. The Mountain Ash.—G. D. 1, *Hemerocallis graminea*; 2, *Ilex latifolia*; 3, *Kalmia latifolia*; 4, *Veronica gentianoides*; 5, *Saxifraga granulata*, flore-pleno; 6, *Begonia Mrs. Anna Low*; 7, *Ornithogalum umbellatum*; 8, *Linaris cymbalaria*.

NUSSERY.—H. J. G. For localities in which to start, see last week's *Gardeners' Chronicle*, in "Answers to Correspondents." For names of glasshouse-builders, scan our advertisement columns.

PEONIES.—Miss R. W. We cannot undertake to name the varieties. Send to a specialist—say Mr. Kewley, The Nurseries, Langport, Somersetshire.

PEARLGRUBS.—J. S. The plants are perfectly free from fungoid and bacterial disease. The cause is evidently due to some cultural defect. The cuttings used may not be sufficiently mature for giving the best results. *G. M.*

TOMATOES FOR MARKET.—H. J. G. Each grower has his special variety; some are better croppers than others: Chemin, Conference (Chiswick), a cross between Horsford's Prelude and Perfection; and Acme, are excellent. Criterion, a pink fruited variety, is a good setter, especially in the winter; Ne Plus Ultra, syn. Dehlan Favourite, is a good setter, and the fruit of fine flavor; Hilda's Wonder is another fine fruiter, and the fruit of good flavor; Blenheim Orange, a rich orange-shaded red-outroued fruit, of delicious, briskly acid flavor; and Golden Queen is a good companion to the last-named. One of the heaviest croppers is Nesbie's Red (Veitch's), a rather small Pear-shaped fruit, abundantly produced, not, therefore, so suitable as the other, as a market variety.

VINE BORDER AND VARIETIES OF GRAPE TO GROW.—H. J. G. The instructions for making a Vine-border are too lengthy to find a place in this column, and we should therefore advise you to purchase a manual on Vine culture—say Barron's or Molyneux's; the former obtainable at the *Journal of Horticulture* Office, 171, Fleet Street, E.C., and the other at the *Bazaar* Office, 170, Strand, W.C.

VINE LEAVES.—E. J. H. There is no mildew present, neither Phylloxera, but the appearance of the leaves suggests a want of air at the roots. *G. M.*

VINE LEAVES SPOTTED.—F. M. The spotting of the leaves is due to the sulphur. The foliage should be dry when sulphur is put on the pipes; otherwise the sun's heat, joined with the water to form an acid, which scorches the leaves. *G. M.*

WATER THAT CONTAINS IRON.—S. X. Water that contains much iron is not good for plants; a small amount present in the soil is good for the Oak, and may not be inimical to fruit-trees growing in the open ground. Everything depends upon the percentage of iron present in the water. Why not make a few experiments with plants in pots, and in the open ground?

COMMUNICATIONS RECEIVED.—Schlop Brothers; too late for this week.—Anxious Violet.—A. K. B.—Shirley.—Mottet.—W. C.—G. B.—C. B.—W. C.—B. Havant.—A. Lohrer. Monica.—A. G. B.—Dr. F. G. Danmer.—H. H. C. SATURDAY, JUNE 5, 1897.

AGRICULTURAL ESTATES.

ONE of the most interesting, and at the same time most important books that have been recently published is that entitled *A Great Agricultural Estate*, being the story of the origin and administration of Woburn and Thorney by the Duke of Bedford.* Rarely, indeed, have we perused a book so full of interest. For the most part it deals with agricultural subjects, but horticulture and fruit-culture are also touched upon; and, indeed, much of the book is applicable to each and any branch of plant-culture. The book took origin from a speech delivered by the Duke, in which he endeavoured to show from the history of Thorney, one of the estates above mentioned, that while the circumstances of the labourers had improved, taxation, both local and imperial, had increased, and that rent had disappeared not only from Thorney, but also from the Bedfordshire and Buckinghamshire estates. The possession of these properties, even after excluding all expenditure on the abbey, park, and farm at Woburn, now involves upon their owner a heavy annual loss. "I further attempted to show," writes the author, "how none of the responsibility generally regarded as inseparable from the position of a great landlord had been evaded, even though the burden borne by the one individual person connected with Thorney who obtained nothing from it, was only recompensed by the feeling that he was instrumental in maintaining a system which in the past had added, and in the present is still adding, to the welfare of thousands." The book before us is an expansion of the same topic, and the details relating to Woburn are added to those of Thorney.

Some portions of the book necessarily touch upon matters of controversy between politicians of opposite schools. The Duke, while not ignoring such contentious matters, confines himself mainly to details and matters of fact, to which the most sensitive or prejudiced individual cannot object. We do not care in these pages to touch on any party politics, but we welcome the careful and scientific way in which the facts of the case are collected, grouped, and weighed, feeling certain that evidence so carefully and clearly stated must be of the utmost importance in the settlement of doubtful points. The only remark we feel disposed to make in this connection is, that all great estates have not been, and are not, managed with such sustained generosity, nor on so continuous a plan.

The first chapter of the volume before us contains a very condensed history of the Bedford

family from 1486 to 1895, from which it is seen that the Russells, from the time of the third Earl to the present time, have identified themselves with the improvement of the soil. Landscape-gardening, reclamation of fen-land, arboriculture, high farming, and stock breeding, housing of agricultural labourers, education of the rural population, and experimental farms, "form the history of the race in connection with the lands they owned."

A long quotation from the works of Sir W. Temple (1720) describes the garden at Moor Park, made by the Countess of Bedford as "the perfectest figure of a garden."

The garden was terraced and formal with fountains and statues, shell-rockwork, and other decorations not to the taste of the present generation. The fifth Earl of Bedford became the first duke, and his successor, Wriothsley, was a correspondent of Sloane's, and devoted to floriculture and agriculture. John, the fourth Duke, took special interest in planting, and called in Philip Miller to his aid. His handiwork is everywhere apparent at Woburn. Francis, the fifth duke, founded a local agricultural society when such institutions were unknown; he also started a model farm of 300 acres. The sixth duke loyally maintained the agricultural traditions of Woburn. His successor was even more devoted to agricultural improvements, drainage, farmsteads and cottages, and so on. The record is substantially the same up to the time of the tenth duke. We must pass over, as not directly relevant to horticulture, the wonderful story of the great Bedford level.

The chapter on financial results is one that will be turned to by economists and statisticians. The appendices contain full details of income and expenditure on the two estates from 1816 to 1895 inclusive. On the Thorney property the expenditure for the period named was £1,398,353, and on Woburn for the like period £2,632,186. The loss at the present time amounts to more than £7000 per annum.

The sum expended on new works and permanent improvements at Thorney from 1816—1895 was £265,155, and at Woburn £537,347 for the same time. The average net income from Thorney for the last twenty years is 2½ per cent. on the capital outlay for new works, and from Woburn barely 1 per cent. We content ourselves with quoting these striking figures without discussing the Duke's deductions from them. The estates, in fact, have been managed not on commercial principles but for the benefit of the tenantry, and of the community at large. No money loss has been allowed to interfere with the improvement of the farmsteads and cottages, and remissions of rent have been constant. The total amount disbursed between 1856 and 1895 in the shape of contributions to churches, schools, gifts, pensions, and the like, was £289,923, the net income being £300,024. In nine years of deficit, amounting on the whole to £61,005, the sum expended for charitable purposes was £97,229. The average annual expenditure on charities amounted to £7248; and in the years of deficit the voluntary payments, so far from being curtailed, reached the larger average of £10,803.

Turning over the pages of the volume, we find that on the Thorney estate, there are 210 cottages having gardens, the total extent of which gives an average of 52½ poles to each cottage. As to allotments, the Duke's experience leads him to think that one quarter of an acre of cottage garden will tax to the utmost the energies of a labourer in full work, and that

a man who thoroughly cultivates an acre of land grows more than he can consume, and must face the casualties of that hazardous trade—agriculture. Small holdings (20 to 25 acres) have nevertheless proved an undoubted success.

The eighth chapter will have special interest to our readers, as containing an account of the experimental farm and of the experimental fruit-farm. The latter is to be an experimental station, where horticultural questions and problems are dealt with in the same manner as agricultural questions are at the station of the Royal Agricultural Society, also maintained at the cost of the Duke. We shall defer further notice of the fruit-farm till an early number, when we shall be in a position to comment on the "First Report of the Working and Results of the Woburn Experimental Fruit-Farm," by the Duke of Bedford and Sir Spencer Picken- ing," a copy of which has just reached us. A sentence will show the spirit in which the stations are worked. "Every investigation, however abstruse or scientific in its nature, must be considered as having a prospective, practical value if it tends to increase our general knowledge of the subject."

After a description of the experimental fruit-culture station, we have accounts of the farm-school, with full details of the system pursued. The lads have to work from 5.30 A.M. till 6 P.M., with intervals for meals; and the training they receive is partly practical, partly scientific—that is, they are taught to work with their heads as well as with their hands.

In the appendices are given, as we have stated, the statistical details of income and expenditure from 1816 to 1895, upon which the comments and inferences of the text are based, and these are followed by an index, which renders the consultation of the work easy.

As we have said, party politicians will look on this book with different eyes according to the sect to which they belong; but those who place the welfare of agriculture and horticulture in the first line, and party politics in the rear, will read this book with eager interest, and feel a sense of gratitude to the Duke of Bedford, not only for maintaining the traditions of his house, but for laying before the public in so clear, unprejudiced a manner the story of a great agricultural estate.

ORCHID NOTES AND GLEANINGS.

DISA HARVEIANA AND D. LUGENS.

Two more very dissimilar and extraordinary species of *Disa* have to be added to the steadily increasing list of varieties which have flowered under cultivation, the two above-mentioned kinds having bloomed with F. W. Moore, Esq., at the Royal Botanic Gardens, Glasnevin, Dublin. So unlike each other are the specimens sent, that it is difficult to recognise them as of the same species, though the apparently irreconcilable difference is chiefly in the labellum, that of *D. lugens* being about an inch in length, and three quarters of an inch in width, and so finely cut and divided as to resemble a piece of very delicate moss; while the same organ in *D. harveiana* is merely a small, plain, linear-lanceolate blade. The spur of *D. lugens* is very short, while that of *D. harveiana* exceeds 2 inches in length. *D. lugens*, which belongs to the grass-leaved section, has elegant spikes of flowers, with the gales pale lilac striped with green, and with the before-mentioned lacinate multifid tip of a peculiar green hue, these two organs forming the conspicuous part of the flower. *D. harveiana* bears few-flowered spikes, each flower, when expanded, being 1½ inch at the greatest width; the segments more similar and

equal than usually seen in the genus; in colour pinkish-white, with some purple lines on the petals, and spots on the opening of the inconspicuous galea, which finishes in a long spur. It is a near ally of *D. Dracois*, the only other species which resembles it. The flowering of these two species at Glasnevin proves that time only is required to acclimatise these terrestrials, which resent removal very much, and lie apparently inert for years, during which they are frequently thrown away as dead. Few things are more difficult, however, to kill by fair means, and if carefully tended, they reward with their flowers in time. *J. O. B.*

MANCHESTER AND NORTH OF ENGLAND ORCHID SOCIETY'S AWARDS.

It does not seem to be generally known that the object of this society is to establish a full record of all the sterling good Orchids in cultivation from whomsoever presented, and they have instructed their committee to recognise all such, either by First class Certificates or Awards of Merit. When this record has been fully established, then their duty will be to limit their honours, after the manner of the Orchid Committee of the Royal Horticultural Society; although it may not be at all times desirable to pass over a very superior form of any species that they may have had a First class Certificate, if the plant candidate in the wisdom of the adjudicators is better than any similar one so honoured that has been entered upon the society's records. *J. A.*

CROZY AND HIS CANNAS.

"I began," says Mr. Crozy in *Moller's Deutsche Garten-Zeitung*, "hybridization between *Canna Warszewiczii* and *C. nepalensis*, a variety with large yellow flowers, and very long creeping tubers. My first Cannas obtained from this cross were named *Boulet* and *Plantieri*, the latter of which showed green foliage and orange flowers. The first one came close to *C. Warszewiczii*, with dark red-brown foliage and pretty large flowers, was very free flowering, and a favourite for some time. After this, by crossing with *C. aureo-picta*, I succeeded in getting hybrids with yellow-spotted flowers, which year by year grew larger and rounder. I then tried to get an early bloomer, and finally succeeded in obtaining a type which was very floriferous. I constantly threw inferior plants away, and kept only the best.

"As to the number of crosses raised by me, I suppose that I have raised, without exaggeration, some 180 to 200 varieties, which, step by step, showed improvement over the older kinds. Among my varieties not yet in commerce, are Cannas with flowers measuring from 4½ to 6 inches in diameter. These have all very glowing colours, and bear immense flower trusses.

"My constant year for superior varieties show success every year in regard to colour as well as size and number of flowers. The flowers now are borne more erect, are of better substance, and show broader, rounder petals, and some are of a size not known before.

"The Cannas for our climate have the advantage of being dwarf and early flowering, and they stand rain and other adverse weather conditions well, which the older varieties do not."

As regards the new type of Cannas seen in the varieties *Austria* and *Italia*, Mr. Crozy states he awaits the competition of these without fear, and comments adversely on the lack of substance and early wilting of the flowers.

"We may add," says the *Gartner-Zeitung*, "that Mr. Crozy is known in Nancy, France, under the name of 'Papa Canna'; and one of his best novelties is named 'Papa Canna.'"

THE ROSARY.

ROSE PROSPECTS.

The experience of the past few years has shown us how utterly fallacious are all prognostications as to the character of the Rose season. Promising expect-

tations have been suddenly blighted by one cause or another; and, in fact, in our variable climate there is really no certainty. For instance, we are now in the early part of June, and if we might believe the rapturous ecstasies of poets, nothing but balmy airs and bright suns are to be expected—but we prosaic people know otherwise. We have not had a thoroughly good Rose season for some time, and we should be especially thankful this year to be favoured with one. At any rate, I think we may say that there is not much fear of drought; in fact, in many districts where the soil is heavy, Rose-gardens may be described as waterlogged—the heavy, drenching rains of autumn and early winter completely saturated the soil, while the rains which we have had the last two months have kept up the moisture. I do not see, however, that all this has so much interfered with the ripening of the wood as might have been expected. Since their pruning, the plants have started well, and promise at present an abundance of healthy buds; in fact, the whole of this subject of ripening wood seems to me a question of considerable doubt, for the same thing applies to fruit trees. We cannot, of course, as yet see how the fruit will set, but never was there a more abundant show of blossom. [This does not apply in Middlesex, Ed.] Some tell us that all this is fallacious, and that the fruit will not set well; and so they tell us about our Roses, not to be too sure. Well, we shall see, and ask in the meantime whether there is anything to be done.

In this district the Rose-maggot has not yet put in an appearance, but I suppose we may soon expect his not over-gentle attentions; there is but one way of combating this pest, and that is by hand-picking, and this must be done as soon as the maggot makes its appearance. If it were only to roll up the leaf, we might, however disfiguring it may be, put up with it; but, unfortunately, it attaches the leaf to the bud, at which it gnaws away, and so effectually destroys the flower. And so also if aphid appears, care must be taken to syringe the plant effectually; beyond this, I hardly know of anything that is very urgent for the amateur's Rose garden at present. The uncertainty which hangs about the prospect of Roses themselves also affects the Rose exhibitions, and naturally so, and probably more uncertainty is connected with our National Rose Society's exhibitions than usual. The event which will principally occupy the minds of our people this year is a very disturbing element in the calculation of many things; it has already affected the dates of two of our exhibitions. The southern exhibition, to be held at Portsmouth, was originally fixed for June 23, the day after the one for the celebration of Her Majesty's sixty years of sovereignty, and as that day will be a Bank Holiday, it is manifestly impossible to expect Rose-growers to travel on it; therefore it was decided by the local authorities, and fully endorsed by the committee of the National Rose Society, to put the show back, and consequently it will be held on the 18th—in fact, the authorities of Portsmouth during the whole of the Jubilee week will be occupied with something connected with it. This is the earliest date at which the Society has ever held an exhibition, and it is not much earlier than some of the exhibitions of local societies. Rose-growers in the Isle of Wight and other early places have long called out for a show which would be more suited for them; they will have it now, and let us hope they will come out in strong force. Then there are other places along the southern coast, such as Torquay and Exeter, to whom it ought to be acceptable; while I think it most likely Colchester, Chelmsford, Canterbury, and Reigate, all early places, will be able to enter the lists. The date of the metropolitian show has been also altered for the same reason; hitherto the exhibition there has always been held on a Saturday, and as it is well known that the parsons are a strong element in the Rose-growing world, many will hail with satisfaction the arrangement that has made changing the day from Saturday to Friday necessary—but not, however, on their account, and I think that unless we have a very unpropitious season, it ought to be the grandest Rose show that has ever been held. There are more

classes than ever, the special prizes are numerous, and the prizes offered for dinner-table decoration with Roses ought to prove a very attractive feature, and as people will have recovered from the intoxication of the Jubilee week, it is to be hoped that all will go pleasantly and well. It must be remembered that we have no longer the experience of Mr. Head at our command, but I am sure one has only to ask Rose exhibitors kindly to consider this, and to help the new superintendent, Mr. Casleton. A little consideration of these circumstances will, I am sure, greatly help him. The exhibition will be held in the central transept, but the space will be much larger than that which has been previously available; there will be more room for moving about, and altogether the position will be, I believe, a suitable one.

The northern provincial show will be for the first time held in East Anglia, under the auspices of the Norfolk and Norwich Association, and as there has been for many years a flourishing society there, which seems to have been excellently managed, we may anticipate a successful meeting. There is one matter, however, which we have to take into account, that the date is considerably later than that on which the Rose show is usually held in Norwich, and many have complained that it is out of the way, and that it is not sufficiently northern; we must recollect, however, that our society is a national one, and must consult the wishes of its members in all parts of the country.

In looking forward to the Rose season there is one point always of interest: what shall we see in the way of new Roses? will those which were "decorated" last year fulfil our anticipations, and shall we receive any additions of value amongst this year's Roses? I have been obligingly furnished by Messrs. Alex. Dickson & Son of Newtownards with a list of the novelties, both home and foreign, which may be looked for this season. I do not anticipate that we shall see much of the foreign Roses, as the plants which arrive over here are mostly cut up for propagation, and are not likely therefore to give very good exhibition blooms; the greater proportion of them seem to be Teas and Hybrid-teas—many of them have striking descriptions, showing wonderful combinations of colour! The great success of *Crimson Rambler* has led Mr. Lambert, of Trèves, to attempt to raise others of the same character in different colours, and we have consequently three of this class—*Aglaia*, which is described as a yellow rambler, of the same habit as *Crimson Rambler*, with pyramidal masses of bloom, and of a Teas scent; *Euphrosyne*, a pink rambler, said to be bright carmine in colour when in bud, and when fully opened the yellow anthers are said to produce a pleasing effect; *Thalia*, a white rambler, of the same character as the preceding, with abundance of flower. If these justify the descriptions that have been given of them, they ought to be valuable additions to our pillar-Roses.

In home-raised varieties we are on safer ground, many of them we have seen, and they are more likely to be brought forward in good condition than those from foreign sources; all rosarians will be anxious to see whether *Muriel Graham* sustains the character she gained last year. I have seen in a contemporary that Mr. Lindsell forwarded some blooms, and that he maintains the same high opinion with regard to its merits that he did last year. As the new pedigree Roses from the same firm, Messrs. Alex. Dickson & Sons, we have Countess of Caledon, which has been several times exhibited, and seems to have met with a good deal of favour; it is a rich carmine-rose in colour, very vigorous in habit, and very free flowering. *Miss Ethel Richardson* is almost pure white with flush-tinted centre, the flowers are large, imbricated, with high centre; it is described as only moderate in growth and very free flowering. *Robert Duncan*, of vigorous growth and free flowering, suitable for garden decoration as well as exhibition purposes, but the colour is described as "rosy lake," and this, very often in other Roses, passes off to a magenta, which is a colour I do not quite like in the Rose. Messrs. Wm. Paul & Son have announced *Empress Alexandra* (of Russia), which is described as a rich lake-red, shaded with orange and fiery-crimson—one of the globular Teas, full and large

and vigorous in habit [Exhibited at the Temple Show, where it attracted much attention from the novelty of its colours. ED.]; and Waltham Standard, which they describe as brilliant carmine, shaded with scarlet and violet—the flower is said to be in shape and character of “A. K. Williams,” also vigorous in growth and with fine foliage. Messrs. Paul & Son announce a promising Rose, bearing the name of that well known rosarian, Alan Charles; it is said to be a large rosette-shaped flower of pure lake colour, and on the reflex of the petals silvery-white, very vigorous and free-flowering.

There will also be the Roses which were much thought of last year, and whose behaviour in the present we shall be anxious to see, such as Messrs. Cooling & Son's Bladud and Lawrence Allen. Paul & Son's Haileybury, Wm. Paul & Son's Enchantress,

and *Ordering them, &c.*, Oxford, 1657, with the engraved title by Goddard. £4 4s.; C. Bowles, *The Florist*, with sixty plates in colours of flowers “regularly disposed in their succession of blowing,” 1777, £9 5s.; J. Boyceau, *Traité du Jardinage qui enseigne les Ouvrages qu'il faut faire pour avoir un Jardin dans Sa perfection, &c.*, Paris, 1688, with eighty-six portraits, and beautiful folding plates of plans of gardens, a very rare work, £9 5s.; P. Alpin, *De Plantis Exoticis*, with beautiful engravings, Venice, 1627, £4; M. Bulliard, *Flora Parisiensis*, Paris, 1776-80, a fine copy on “large paper,” with upwards of 600 coloured engravings of flowers, fruit, &c., in six volumes, £10 15s.; D. H. Cause, *De Koninglycke Hortenijc Aanzeynde de Middelen om Boomcn &c.*, and J. Commelyn, *Neidelantse Hesperides*, Amsterdam, 1676, with plates, two volumes in one,

della villa di Castellazzo, descriptions in verse, plates of gardens, &c., Milan, 1743, £2; *Fruit Walls Improved by inclining them to the Horizon*, with folding plates, frontispiece by Grisebin, a presentation copy from the author, whose name is not given, 1699, £3 5s.; J. Vander Groen, *Jardinier du Pays Bas*, with plans of gardens, arbores, illustrations of gardening tools, fountains, grafting, &c., Brussels, 1672, £7 15s.; M. Jacques, *Nouveaux Livre de Fleurs*, the complete series of six plates, engraved by Tardieu, Paris, 1760, £3 3s.; W. Lawson, *New Orchard and Garden*, with curious woodcuts, a fine copy, 1666, £2; L. Mesger, *The English Gardener*, or a sure guide to young planters and gardeners, with numerous plans of gardens, in the original calf, a rare work unknown to Lowndes, 1670, £9 9s.; *Neues Blauen-buechlein nachten Leber Anwerthen*, with beautiful engravings of flowers, 1709, £3 12s.; J. L. Prevost, *Collection des Fleurs et des Fruits peints d'après Nature*, fine plates in colours, Paris, 1805, £5 15s.; M. de Ros-st, *L'Agriculture*, a poem, with fine plates by St. Quantin, Louthembourg, and Marillier, Paris, 1774-82, £3 3s.; *Systema Horticulturæ*, or the art of gardening, with beautiful plates by Van Hore, of gardens, fountains, &c., a fine copy of this very rare book, 1667, £2 2s.; L. Tessier, *Livre de Principes de Fleurs*, beautiful plates, in two states, Paris, 1770, £2 2s.; *The Flower-garden*, “displayed in above 400 curious representations of most beautiful flowers regularly disposed in the respective months of their blossom,” fine engravings, 1734, £13 15s.; G. Thouin, *Plans Raisonnés de Toutes les Espèces de Jardins*, coloured plates, Paris, 1820, £2 6s.; M. A. Villi, *Catalogus Plantarum Horti Pisani*, portrait and plates, Florence, 1725, £2 2s.; and G. Zanoni, *Istoria Botanica nella quale si descrivono alcune Piante de gl'Antichi*, fine engravings of flowers, Bologna, 1675, £2 2s. W. Roberts.

FIG. 133. ODONTOGLOSSUM CRISPEUM “STARLIGHT”; COLOUR WHITE, SLIGHTLY TINGED WITH PINK, AND RED-BROWN BLOTCHES.

(Exhibited by R. Brooman White, Esq. See Report of the Temple Show, in *Gardener's Chronicle*, May 24, 1897.)

Mr. May's Mrs. Pierpoint Morgan, Mr. Frank Cant's Mrs. Frank Cant, and Mr. Rousey's Mrs. Rousey; and there will also be some new varieties of Lord Penzance's Sweet Briars, which are sent out by Messrs. Keynes, Williams & Co.; so that there will be plenty for Rose-growers wherewith to satisfy their curiosity. *Wild Rose.*

RARE BOOKS ON GARDENING.

THERE is a very distinct revival in the interest in the older works relating to gardening, flowers, &c., and booksellers have come to regard them as property of considerable value. A collection of over forty lots, formed by an anonymous vendor, was sold last week at Messrs. Sotheby's, and many of the items realised noteworthy prices. The following list includes the principal lots—R. Austen, *Treatise of Fruit Trees, showing the Manner of Grafting, Setting, Pruning,*

£11 5s.; F. Colmina, *Plantarum alijquat Historia*, with fine plates, Naples, 1592, £2 2s.; Crispin de Pas, *Designs of flowers*, eight beautiful plates, in folio, no date, £12 10s.; De Re, *Hortensis Libellus Vulgaris Herbarum, &c.*, 1539, £2 6s.; John Dunstall, *Third Book of Flowers, Fruit, Beasts, Birds and Flics*, “exactly drawn,” plates, 1661, £9 5s.; *Eden, or a Complete Drawy of Gardening*, with numerous plates, a fine copy, 1757, £1 14s.; John Evelyn, *Kalendarian Hortense*, or the Gard'ner's Almanach, directing what he is to do, and what fruits and flowers are in their prime, a fine copy, with frontispiece, 1699, £1 6s.; J. B. Ferrari, *De Porcum Cultura*, with numerous engravings of flowers, gardens, &c., Rome, 1633, £2 10s.; *Floribegium dat ist cin Blumenbuch darwinnen alterhand Blauden ganc Artig mit Liebhaftig Farben*, with numerous curious coloured plates of flowers, garden scenes, grafting, &c., a fine copy, Franckfurt. 1616, £25 10s.; L. Polonio, *Le Diletio*

TREES AND SHRUBS.

THE WHITE SPRUCE (PICEA ALBA).

THIS tree is readily distinguished from the Black Spruce (*P. nigra*) by its smaller size, the lighter colour of its foliage and bark, and its narrow, almost cylindrical cones. Usually it does not succeed so well in this country as the Black Spruce, and in old age is very apt to have a diseased and miserable appearance. In habit the tree is decidedly conical, the branches slightly ascending, and well clothed with greyish-green leaves, each about half an inch long, standing out all around the stem. The cones are nearly 1½ inch long, and are usually produced plentifully. On damp black loam, as well as on greasy yellowish loam, I have known the White Spruce to grow well, a tree on the former soil that I had felled having attained to a height of 41 feet. The timber was white, soft, and easily worked, but did not appear to be of any value—for outdoor work, at least.

P. alba var. *corulica*, which has been referred by some writers to *P. nigra*, and by others classed as a species under the name of *P. rubra*, is of more vigorous growth, and has longer leaves and larger cones than the parent. The plant I have seen, with leaves three-quarters of an inch long, is certainly similar to *P. alba*. *A. J. Webster*. [We should be glad of details concerning the growth in this country of the North Eastern American Spruces, especially *alba* and *rubra*. ED.]

PRUNUS PUMHA (SAND CHERRY).

THE necessity for grouping some kinds of shrubs in order that their full beauty and true character may be shown, is well exemplified by this plant. Grown as a single or isolated specimen it is, perhaps, the least effective of all the Cherries, but how beautiful it may be when brought together in a mass is shown by a large bed of it near the Water Tower at Kew. Here are planted some dozens of this shrub, now about 3 or 4 ft. high, and they have lately been in full flower the branches being thickly set with the small white blossoms. Beneath them the ground was carpeted with

Blue-bells deeper in hue than an Italian sky—the whole was a most lovely picture. *Prunus pumila* is a native of North America, and is a very variable plant. The ordinary form is an erect shrub ranging from 5 to 6 feet in height. It has bright green leaves about 2 inches long, and often glaucous beneath. The flowers are always of some shade of white, but vary in purity, some being quite dull. The plants at Kew have been mostly raised from a form with flowers of a clearer white than usual, which came from Lake Michigan, on whose sandy shores this species grows abundantly.

Far. depressa.—There is a variety of *P. pumila* which has been in cultivation from almost the beginning of the century, and has perfectly prostrate branches. It was called *Prunus depressa* by Pursh, and is described by London in his *Encyclopædia of Trees and Shrubs*, p. 284. In the *Kew list* it is included under *P. pumila*, but from its very distinct habit it deserves to be distinguished as a variety, and for this the old specific name of *depressa* will serve.

LEDUM GLANDULOSUM, Nuttall.

Two species of *Ledum*—*L. palustre* and *L. latifolium*—have for more than a century been well known and popular plants in our gardens; but this species, although named and described by Nuttall, the American botanist, in 1843, and therefore by no means new to botanists, has, until recently, been almost or quite unknown to horticulture in this country. Three years ago seeds of it were sent from the Arnold Arboretum to Kew, and plants raised from them are now in flower. It proves to be not only quite distinct from the others, but so far as can be judged at present, of at least equal beauty. It is a bush of much the same habit as the commoner *Ledums*, but is perhaps, of more open and taller growth, being described as growing from 2 to 6 feet high. Its leaves are very distinct; they are ovate, $\frac{3}{4}$ inch to $1\frac{1}{2}$ inch long, quite glabrous (except for a few hairs when very young), and thickly speckled beneath with minute appressed glands. Two very well-marked characters of *L. palustre* and *L. latifolium*—the rusty-coloured wool on the lower surface of the leaves, and their revolute margins—are quite absent in this. The flowers are slightly larger than those of its allies, but otherwise they are very similar; they are produced at the ends of the shoots in a cluster of several umbels. The five petals are pure white and elliptic ovate, the ten spreading stamens pubescent towards the base. *Ledum glandulosum* is a native of California, British Columbia, and the northern Rocky Mountains. There are specimens in the Kew Herbarium, gathered by Sir J. Hooker and Asa Gray in South California in 1877, with leaves 2½ inches long, and nearly 1 inch wide. *H. J. Bates.*

FORESTRY.

TYPES OF BRITISH WOODLAND.

(Continued from p. 295.)

MIXED PLANTATIONS.—When we come to discuss the principles on which a mixed plantation should be formed, difficulties at once arise. The first point to be settled, of course, is: What is the planter's object in view? Is it profit, ornament, game-cover, or a combination of all three? Probably the last of these is the prevailing one, to which may be added the desire to get an effect as quickly as possible. It is evidently little short of impossible, therefore, to lay down any principle which would be applicable in such cases, for no two planters possess similar views on all the above-named subjects. The question as to what constitutes ornament in a mixed wood can never be satisfactorily answered to suit all tastes. One may find his *beau idéal* in the guarded and scrubby holt and spreading crown which trees of unrestricted growth freely possess; while another regards tall, clean stems, as the proper type of plantation tree. With regard to species, again, most of us evince a preference for some particular species or genus, and, if possible, we like to get this freely represented in our plantations. All such differences

of opinion have to be studied both in the planting and subsequent treatment of a mixed wood, although we are afraid that the slight probability of a planter seeing his ideas fully carried into effect during his own lifetime leads in most cases to immediate rather than to after-effect being most studied. It seems, however, somewhat of an anomaly that while gardens, pleasure-grounds, and parks, are usually subjected to critical treatment, woods are planted and managed on lines which are neither justified by æsthetic nor economic principles. In the first place, what are the æsthetic functions which estate woodlands ought to fulfil? These vary to some extent with the physical features and configuration of the ground, in some cases, the improvement of an extensive landscape, or the variation of a flat and unbroken plain; in others, the provision of special features in the more immediate surroundings of a country residence. But, in any case, we consider the peculiar function which all woods ought to fulfil is that of representing the natural forest growth with which Nature, when left to herself, supplies every part of the country. The position and extent of this growth must be decided by the landscape gardener, after due consideration of economic principles and local circumstances, but the intercal arrangement and treatment must be chiefly left to the forester. The latter endeavours, as far as possible to plant those species which are best adapted to the soil and situation. In most cases the chief difficulty consists in deciding not what, but what not to plant, so many are the species which adapt themselves to any particular soil and situation, and so varied the latter on any area of great extent. These are the chief reasons which have rendered mixed plantations so general, and while the idea which is chiefly responsible for their formation may be right in principle, the principle has gradually been lost sight of in a more or less rule-of-thumb practice, which, as already said, is neither ornamental nor economical.

It is not a difficult matter to condemn generally any established custom—first, because every custom has its weak points; and, second, because general remarks are not easily contradicted. If we are to justify our condemnation of mixed woods, therefore, we must descend to details. First, then, what are the chief failings of the ordinary mixture as a picturesque combination of different species? For one thing, it lacks decision of character. The characteristic effect produced by a group of any one species is entirely lost owing to individuals of each of the kinds represented being separated by other individual trees of, perhaps, a totally different habit of growth. During the early stages, the effect of this is not altogether displeasing, as each tree being practically isolated from its neighbours, the attention is more readily concentrated upon individual trees than upon a compound mass of stem and foliage. But when, as sooner or later occurs, the crowns of individual trees become merged into a solid mass, their respective characters are lost, and instead of acquiring, as is the case with an unmixt group, a new but still distinctive character, the plantation becomes a mere jumble of stems and branches in various stages of tree development. Another disagreeable feature is the general uniformity in the growth of the plantation, which prevents the light-and-shade effect upon which the beauty of woodlands greatly depends. The difference in the rate of growth of the various species furnishes such an effect to some extent; but owing to the too regular distribution of species, the general effect is too uniform to produce that which results from bold groups standing out above their neighbours, which at once attract the attention and relieve the eye. *A. C. Forbes.*

(To be continued.)

GREENLANDS, HENLEY-ON-THAMES.

WHAT this estate originally sprang from, can only be conjectured; but the village of Hambleden, which is on the left bank of the river Thames as it runs from Henley towards London, and the estate of Greenland, now the seat of the Hon. W. F. D.

Smith, M.P., are places of somewhat ancient date, as appears from several memorials in the handsome and commodious old church. By the will of Lady Periam, who died in May, 1621, and whose first husband was a Sir Robert Doyley, it would appear that the house was of great size, and richly furnished. There are memorials of the Doyleys in Hambleden Church. A Sir John Doyley resided at Greenland at the commencement of the Great Rebellion, and being attached to the royal cause, the mansion was converted into a garrison. In 1644, it underwent a long siege from the parliamentary forces, first under Lord Essex, and subsequently under Major-Gen. Brown, who planted batteries on the opposite side of the river, and so fired upon the mansion as to reduce it to a heap of ruins. The garrison eventually surrendered, but were permitted to march out with all the honours of war. In making alterations in the gardens and grounds, arms and implements of war have been dug up, and some of the old cannon balls are preserved on the terrace, and what are considered to be the foundations of the old mansion have been laid bare nearer the river. Previous to the purchase of the estate by the late Rt. Hon. W. H. Smith, M.P., some twenty-five years ago, Greenland was in the possession of the Majoribank's family. Soon after Mr. Smith became the owner, he considerably enlarged the house by adding two wings, and made other additions of value. The white mansion occupies a commanding position near the river, and has in the rear a dense back green of noble trees and shrubs; it is a conspicuous object on coming down or going up the river; and on the opposite side green fields stretch away to a considerable distance. The famous Henley race-course terminates near the mansion; lower down the river is the boat-house, and farther on Hambleden Weir and Lock. The late Mr. Smith made considerable additions to the gardens, glasshouses, and out-buildings; and the present possessor is greatly improving the estate in various ways. In extent it runs down to Henley, and in the opposite direction to between three and four miles beyond Hambleden, and on both sides of the river for a considerable distance.

There are two walled-in kitchen gardens, one near the residence, the other divided from the house grounds by the main road from Henley to Maidenhead, and both gardens slope towards the south, and each have their complement of plant-houses. The residence of Mr. Henry Perkins, who has charge of Greenland, is on the side opposite to the mansion, and it is close to the walled-in garden; by its side is a postal and telegraph office in charge of Mr. Perkins, who fills the post of sub-postmaster of the Greenland district. In this square-walled garden, situated upon its summit, and with a south aspect, is a range of six fruit-houses, three of them orchard-houses, and three vineries; in the former, Figs in pots are largely grown. Brown Turkey, Negro Largo, Osborn's Profitic, and others. They are started into growth in November, and freely fed with blood-manure, applied in a liquid form. A good supply of Figs is thus obtained up to autumn, the earliest crop ripens about the end of April. Peaches and Pears are also grown in pots, in all cases blooming freely, and setting their fruits abundantly.

The earliest crop of Strawberries is taken from Stevens' Wonder. It does so well here that it will take the place of *La Grosse Sucrée*, though some say it does not force well in other places. About two thousand plants were grown for early crops, followed by *La Grosse Sucrée* and Royal Sovereign. Osborn's Forcing French Beau is largely grown for early crops. In one of these orchard-houses could be seen a number of *Chrysanthemus*, which had been grown for a supply of late bloom, raised from cuttings rooted in April and May. When the plants have done flowering, and thrown up suckers, they are reduced to one, then the soil is shaken from the roots, re-potted, and very fine free-blooming plants are obtained in this way. About 1000 specimens are grown for cut bloom.

Mr. Perkins is a seedling raiser also, and has a number raised from seeds of some of the very best varieties, from which he hopes to obtain some things

of high merit. As a cultivator and exhibitor he is widely known, and at the last December exhibition of the National Chrysanthemum Society at the Royal Aquarium he took several of the leading prizes. In early April his plants were a treat to see—full of promise for the coming shows. A collection of 300 named varieties is certain to contain the very cream of the newer introductions.

Mr. Perkins takes his earliest supply of Grapes from pot Vines, which at the time of our visit promised remarkably well, and are ripe the second week in April. In the case of the three vineries following the orchard-house, one contained West St. Peters and Madresfield Court; the second white Muscats, breaking splendidly from Vines twenty years old; the third Lady Downes' and Alicante.

There are several small plant-houses devoted to the growth of plants for furnishing cut flowers, and for town supply—Roses especially. There are ferneries behind the vineries on the river side, and a

siderable variety. A striking feature at Greenlands during the autumn, through the winter and up to late spring, is the Hippeastrums. Both as a cultivator and raiser, Mr. Perkins has proved very successful. He began cultivating some ten years ago, taking in hand seedlings, and by means of selecting the best varieties for cross-fertilisation, each succeeding season saw some improvement. Flowers of good form are the seed parents, and varieties of clear and distinct colours supply the pollen. Fertilisation is done when the flowers are sufficiently developed; the seed ripens in August and September, and then it is either sown at once, or in the following spring, in pans of light soil; they germinate quickly—in a week or so. When the plants are large enough, they are potted off singly and kept growing on. Some will flower the second year, the majority during the third year. Mr. Perkins adopts the practice of keeping his seedlings growing on till they bloom, not allowing them any resting time; then when they have bloomed they are repotted,

valuable late variety. *Dendrobium nobile* Cooksoni is also very fine, and Mr. Perkins has a very handsome form of *Calanthe Veitchii*. *Dendrobiums* are in good variety; among them a very large and grandly-flowered specimen of *D. thyrsiflorum*. There is also a fine variety of *Cypripedium villosulum*. Cool Orchids are also well represented.

The place is so extensive, and there is so much glass, that material could be found for a very lengthy notice. Excellent order and high cultivation are observed on every hand; the grounds are delightful, and in the height of summer must be charming in the extreme. Mr. Perkins has the entire confidence of his employer, and has important duties to fulfil in the estate lying beyond the limits of the garden. *K. D.*

SEED TRADE.

THE SEED CROPS IN THE SOUTH OF FRANCE, 1896. —In a general way it may be said that the season of 1896 was a fairly bright one for the harvesting of seeds. The harvest of Lucerne in Provence was far from having been abundant; want of seed for stock compelled the proprietors to mow their fields of Lucerne instead of letting them stand for the production of seed. The small area which was not sown gave a fair yield, fine in colour, being only somewhat small in size of seeds. Red Clover likewise was a bad crop or total failure from the same cause—drought and lack of green food. Fortunately there remained a large stock of seeds from the year 1895, which permitted the dealers to complete all the orders on hand. *Avena elatior*, *Bromus*, *Dactylis*, specially grown in the Nimes district proved satisfactory. The crops of Carrot and Mangold Wurzel were entirely bad. Heavy production in other countries, combined with excessively low prices, have discouraged our growers from continuing the cultivation of these seeds, especially Mangold Wurzel. I express the wish that, like our growers, many raisers of the seeds should stop for some years the production in order to diminish the stocks of seed on hand, and, by so doing, improve the price, which doubtless would occur in a few years. Scarcely any roots were planted in the present year. The harvest of vegetable seeds was generally very weak; and taken as a whole, the crop of seeds in 1896 was a very small one in Southern France. The crops are in some years much injured by heavy winds, and the lack of moisture also injures them greatly. *Jacques Rolland, Seed Merchant and Grower.*

FIG. 134.—CYRTOPODIUM CHAPMANI MAGNIFICUM = BELLATULUM X CURTISII: COLOUR CREAMY-WHITE, SPOTTED WITH PURPLE.

(Exhibited by R. I. Measures, Esq. See Report of the Royal Horticultural Society's Meeting, in *Gardeners' Chronicle*, May 15, 1897.)

house of fine specimen Cliveias, which as they come into bloom are brought into a greater degree of warmth, where they develop superb trusses. *Lagerias* cover the interior of the roof overhead.

Among the great variety of plants grown for decorative purposes may be mentioned the common Asparagus, a few seeds of which are sown in a small pot, and when the plants are from 6 to 9 inches in height, and beautifully green, they are placed in silver vases, and are very effective indeed on a white tablecloth. To set forth in detail the almost numberless subjects grown would occupy too much space; *Lilium Harrisii*, *Richardia aethiopica*, and kindred subjects were seen in plenty. Violets in frames are very largely grown, and in many varieties. Mr. Perkins speaks very highly of the large and new Princess of Wales, and the reddish-crimson Admiral Avellan, the first is a most robust grower, and produces its massive blossoms in great abundance.

On the river side there is a range of five vineries, also a very large house for stove and greenhouse plants, filled with a great variety of subjects, at the end of March largely gay with spring flowers in con-

removing the soil at the top and bottom of the ball, and then placing them generally into 32-sized pots. Mr. Perkins holds the varieties are at their best about the third year, after which they degenerate. They throw offsets very sparingly, and they generally flower the next year after being taken off. Potting is done after the blooming season is over, they are kept growing in autumn, and never allowed to become dry; while resting, the bulbs are kept near the glass, and watered once or twice a week. They find a place in the pit during the winter, frost being of course kept from them, and as they come on into bloom, they are taken into the large plant-house. Some flower in December, the bulk in January, February, and March.

The forcing of flowers is done to a very considerable extent, such as *Prescias*, *Tulips*, *Lily of the Valley*, very largely; *Rhododendrons*, *Azaleas*, *Deutzias*, *Dioyltras*, and many other subjects are employed in great quantities—the requirements being extensive.

There is a very good collection of Orchids; among them *Calanthe vestita* Turneri can be noted as a

THE WEEK'S WORK.

THE HARDY FRUIT GARDEN.

By H. W. WARD, Baylough, Essex.

Watering and Mulching.—If not already done, must be attended to. Young Gooseberry and Currant trees, and engrafted fruit-tree stocks of the past and present year's working, should be given a good surface-dressing of manure (in any stage of decomposition) or leaf-mould. The surface of the ground should be first broken up, and the whole should then be thoroughly watered. If these details are attended to, results of the best description are invariably realized in British gardens during the semi-tropical weather, as all crops having soil of average fertility, and being uniformly moist about the roots, must necessarily grow apace, and yield produce fine in size and quality.

The Weather and the Crops.—The fruit trees generally showed an abundance of healthy flowers, which gave promise of beautiful crops. But the weather which was experienced in most parts of these islands during the last four or five weeks have reduced the hopes of many a fruit cultivator to a minimum. From 1° to 9° of frost were experienced on several nights in the month of May. The ground beneath Apple, Pear, Plum, and Cherry trees is strown with the embryo fruits. Trees growing in light shallow soils, necessarily suffering more from drought than those which are planted on heavy land. The Strawberry has also suffered from the effects of these May frosts. As a result of the great loss of fruit, that which remains will necessarily grow to an extra fine size and good quality. The recent rains

will have reached the roots of the trees on every kind of land, even on steep slopes, if it is under cultivation. In the case of orchard trees under grass, it is a good plan, especially in the case of young trees which may not have pushed their roots deeply into the soil, to make a series of holes with a five-tined prong about the trunks of the trees, and extending from 2 to 4 feet therefrom, according to size, so as to admit moisture to the soil. The heavy rains have done much good in freeing the trees from aphides, and to some extent dislodging caterpillars. Where practicable, caterpillars that are left on the trees should be picked off and destroyed; and where this cannot be done by reason of the height of the trees, Paris Green [poison] and water, at the rate of 2 oz. of the former to 25 gallons of the latter, should be applied with a syringe or hand garden-engine, choosing a calm day for applying it, 1 lb. of lime being added to the above mixture, to neutralise the free acid. Paris Green may with advantage be combined with Bordeaux Mixture, by adding 1 oz. of the former to each 15 gallons of the latter.

Strawberry Beds.—The time has arrived when all Strawberry plantations should be strawed down, so as to preserve the fruit in a clean condition. The next best thing to do is to cover them with straw, but little soiled in the stable, which, if put down in rainy weather, is soon washed clean, retaining no odour. The worst material is short grass; long grass is not so objectionable, it rotting less readily.

PLANTS UNDER GLASS.

By G. H. MAYCOCK, GARDENER, LUTON HOO PARK, LUTON.

Warm Greenhouse Rhododendrons.—As these species and varieties pass out of flower, they should be repotted forthwith in fibrous hard peat, and plenty of sharp silver-sand, and some small pieces of charcoal. As in the case of many other hard-wooded plants, the soil should be made very firm around the old ball, and rain-water only used for watering and syringing purposes. It is prudent to repot only such as are gone out of flower, and only sufficient soil should be mixed up at one time as will be required for those plants. The crocking should be carefully done; and in removing the old crocks, care should be taken as not to injure the very delicate hair-like roots. If it be found necessary to reduce the size of the old ball of roots and soil, a sharp-pointed stick, made of Box-wood, should be used, and the roots disentangled without violence; but on no account should this be carried very far, bearing in mind that these Rhododendrons do not possess a very vigorous root-system, and for this reason only a small shift should be given. The supply of water after repotting requires to be very carefully adjusted till such time as the roots have seized upon the new soil, which may occur in from three weeks to a month. After repotting, the plants may be stood on a shelf or bench, according as they are large or small, in the intermediate-house, where they may remain a month, and be removed afterwards to a cool, low-roofed greenhouse for the summer. Syringe them well, affording a slight shade in very bright weather.

Hedychiums.—If the plants of *H. coronarium* and *Gardnerianum* are exceptionally vigorous, and it is thought desirable to increase the size of the pots, the present is a suitable season to repot them. In the case of small potsful of rhizomes divided in the spring, and potted into 4½ and 3½, a shift into 5-inch pots would suffice for the season. Let the new pots be efficiently drained, Hedychiums liking plenty of water when in growth; and as a potting-soil, make use of rich fibry loam three-quarters, and soil, leaf-mould, sand, and charcoal one-quarter. It is a prudent precaution to keep the plants that are repotted in a close pit or frame for a time, and syringe them overhead morning and afternoon.

Primula sinensis.—Seeds may now be sown in mild heat if early flowers are wanted; or well-drained shallow pans, taking care that the soil is neither too wet nor too dry. The seeds should be scattered evenly and thinly on the surface of the soil after this has been made level and smooth, covered lightly with sand and mould, and pressed down with the bottom of a flower-pot, &c. It is well to cover each pan with a sheet of glass, and to place some moss over that. Remove the glass for a time every morning to dissipate moisture till the seedlings appear, when it may be gradually dispensed with.

Cinerarias.—A sowing may now be made in a similar manner to Primulas, but the soil should consist of one-half sand, and one-half leaf-mould.

Place in a cold frame, and shade the seed-pans from direct sunlight, by placing them at the front of the frame, or behind a south wall or hedge. The young plants should be pricked-off into thumb-pots or broad pans as soon as they are large enough to handle; and on the first appearance of green-fly on the plants, an examination should be made occasionally of the under-side of the leaves to ascertain this—see Richards' Vaporiser or Tobacco-fumigator.

Double-flowered Begonias.—Any which are intended for late flowering will be benefited by being syringed, the flowers being constantly removed till the plants have acquired a greater size. These Begonias should be cultivated in a cool-house, and receive slight shade from ardent sunshine. If through pressure of other work at this season repotting cannot be done, apply weak liquid manure-water once or twice a week.

General Work.—See that strong-growing stove and greenhouse climbers do not suffer through inattention to watering or training. Maintain a genial moist atmosphere in the stove, and do not let the air of the greenhouse get acid, shutting up the former early in the afternoon after syringing the inmates, and close the greenhouse after damping the floors by 6 P.M. A greenhouse which does not contain plants in flower, or in which plants that are making flower after having flowered, may be syringed and the floors damped down at 5 P.M., air being admitted at about 8 P.M., more or less in amount according to the state of the weather. Cuttings of *Colocas* and *Acalypha* may be put singly into 3-inch pots for striking; they will make useful stuff for decorating purposes late in the year.

THE KITCHEN GARDEN.

By W. POPE, GARDENER, HIGHCLERE CASTLE, NEWBURY.

Thinning Young Vegetables.—I should like again to draw attention to the importance of thinning the growing vegetable crops in good time as being a chief item in successful kitchen gardening. This applies more particularly to the Carrot, Parsnip, Beetroot, and other deep-rooting plants. In sunny weather like the present, these plants grow very fast, and two or three days' neglect is often sufficient to almost ruin a crop by inducing rankly growth, which renders them susceptible to the ravages of the wireworm and various larvae. In thinning large breadths of any kind of plant, much time is saved if a narrow Dutch or draw-hoe be passed through the lines, so as to leave little bunches of plants at 3 or 4 inches apart, these to be afterwards thinned by hand. It is advisable to go over a lot of plants twice the first time, thinning them to 3 or 4 inches apart, and again as soon as the first true leaf is developed, to 6 or more inches, as may be desirable. The Carrot and Onion quarters or beds should be frequently dressed with fresh soot late in the evening, or in the early morning, that is, when the foliage is moist, soot being distasteful to the various insects that infest these plants in some seasons and localities.

The Planting of Brussels Sprouts and other Cress Crops.—According to the requirements of the family, the gardener will plant out Brussels Sprouts, Savoys, Cauliflowers, and others which may be fit for removal from the nurse or the seed-beds. Brussels Sprouts and Cauliflowers should not, as a rule, be allowed less room than 2 feet from plant to plant, and on strong, rich soils 2½ feet is not too much. These small-growing Savoys, the Early Unn and Tom Thumb, are provided for if planted 1 foot apart, as are also the summer Cabbages of small growth. Should the soil be heavy at planting, the above crops should be deep should be made with the draw-hoe for each row of plants, which should be moistened an hour or so before planting. It will sometimes happen that the plants above-mentioned cannot be set out until the crops of early Potatoes or other vegetables are cleared off, but the plants should not be spoiled in the meantime by remaining crowded together in the seed-bed; rather, thin them out, planting them in nurse beds at 6 inches apart. When land becomes clear, these transplanted things may be lifted, each with a good ball of earth and roots, and be planted with but little check to growth. The draw-hoe should be kept busy amongst growing crops, the remains of crops cleared off the land, and the latter got in readiness for Celery, Runner Beans, &c.

Lettuce.—Seeds of the summer varieties of Lettuce should be sown once in ten days or a fortnight where the plants are to remain, the Lettuce bearing transplantation badly during the heat of summer, unless the plants are prepared in nurse-beds. Plant out good breadths from previous sowings, a good available situation for such plants being the

ridges between the Celery trenches. The Paris Cos under its different names is one of the best Cos varieties for use in the height of summer, bearing in quickly without the trouble of tying, and being crisp and tender eating. Good cabbage varieties are Veitch's Golden Ball and Sutton's Favourite, both handsome and of good quality. Unless wanted for special purposes, clear away all Lettuce plants as soon as they are past their best, the Lettuce being an exhausting crop.

FRUITS UNDER GLASS.

By F. HARRIS, GARDENER, EASTHOR CASTLE, LEDBURY.

Figs.—If treated as recommended in a previous Calendar, the second crop in the early-house will now be swelling fast. Keep all weak growths rubbed off as they appear, and use the syringe frequently until the fruits commence to ripen, but not longer. If the trees are carrying good crops, they should be given liquid-manure, preferably drainings from the farmyard. In the succession-houses the trees will be commencing to swell their fruit; and as signs of ripening appear, keep them dryer both at the roots and atmospherically. Remove any side shoots beyond those required for furnishing the trellis with plenty of air both front and back, to encourage stout, sturdy growth, and good pump joints. Trees in the late-house should be secured by ties as required, but do not tie the shoots down too closely. If the points turn to the sun a little, it is very advantageous to them.

Cucumbers.—The earliest plants may now show signs of exhaustion, but if clean and healthy, they are capable of being brought into bearing again. Clear off all old foliage that is not absolutely required, and take out any old wood that can be spared. Remove all old matting ties, male flowers, &c., and give the plants a good syringing with a little soapy water in which a handful of sulphur has been well mixed. Then take away as much of the old soil from the bed as can be removed without disturbing the roots, and top-dress with a mixture of rough loam, lime rubble, and horse-droppings, in which has been mixed a little good artificial manure. The plants will then be in full bearing again in a very short time. Plants carrying full crops at the present time will require constant attention in stopping and tying of shoots, and in thinning the fruit, &c. Prevent any overcrowding of foliage by removing the oldest leaves. Give good supplies of liquid-manure twice a week with plenty of tepid water, for if Cucumbers become dry at the roots, red-spider will soon appear, and it is very difficult to dislodge. Put out a few plants in frames to keep up the supply when those in the houses begin to weaken, and as the weather will now be getting warmer, the frames will not require so much preparation. Stir up the old stuff, add a few barrowfuls of warm manure, and put in the soil, then close the frames for a day or two, and they will be ready for planting.

THE FLOWER GARDEN.

By CHARLES HERRIS, GARDENER, DROPMORE, MAIDENHEAD.

Planting the Beds.—Now that milder weather and soft winds with rain prevail, if the flower-beds are empty, bedding-out should be pushed on, first using plants that have been well hardened-off. If the plants are afforded water before being planted out, they will go several days without needing any more water. Should a showery day occur, advantage should be taken of it to plant-out the Ten-week, East Lothian, and other kinds of Stocks, German Asters, Zinnias, and all such annuals as are best transplanted in showery weather. If these must be planted in dry weather, shade of some sort should be placed amongst or around them, and strict attention paid to affording water and sprinkling the leaves in the evening.

Bedding-out Sub-tropical Plants.—Now that the welcome showers have moistened the parched crust, bedding-out may be generally undertaken, leaving, however, whatever is susceptible of injury from exposure to cold till a week or a fortnight later. A sub-tropical garden should occupy a sheltered position in the grounds, and if it be screened from the winds coming from the N., N.W., and S.W., so much the better for the plants, although shelter from these quarters is always desirable; the position open to the south and south-east warm being an essential thing in obtaining size and fine colour in the foliage, for without it few of the subjects employed grow satisfactorily. The Canua is of this kind, and the plants being readily

increased during the spring months, plants for putting out in the beds should now be strong, and sufficiently hardened off. These and the Heliconias are plants which one may use with the Ricinus of moderate growth; and if the ground be sumped with Decalys oleosa variegata, and Canas having dark-colored leaves are planted thinly, with a central plant or plants of Ricinus Obermanni, or similar variety, an effective bed will result. Gray-leaved Selinus, such as S. glaucum, also form a suitable undergrowth, being planted somewhat closely, and the splashing of the foliage by rain is obviated. The free-flowering Blue Bell Viola and others may be dotted about among the Sedum. Where Palms are employed, the pots should be sunk in the soil, taking care to place a spadeful of coal-ashes and some soil beneath each. A well-grown Kenia or Scaevola forms a good central plant in a round bed which is to be filled with other sub-tropicals of minor growth. Dracenas, of the indivisa and frons type, are also graceful sub-tropicals. Beds of tuberous Begonias should be planted in sheltered but sunny positions, and if in a spot shaded from the sun at noon, the flowers will be brighter and last longer. Other plants of which the gardener may make effective use are Wigandias caracasana and imperialis; Solanum leucinum, marginatum, robustum, Warscewiczii, Ricinus Gibsoni, R. borboicensis, and others (the last for those who can be made too rich unless the bed be a large one); New Zealand Flax, Perilla nankinensis, Nicotiana glauca, wigandifolia, Tabacum, and others; Greivilleas, of which robusta is a type; Ferdinanda emicans, Daturas chlorantia, fastosa, and Wrightii; Aralias Sieboldii and papyrifera, Zea Caragna, Melastichum major, Humea elegans, and Acaecias in variety. Associated with these as margin or carpet-plants, mention may be made of Amarantus melancholicus ruber and A. tricolor, Artemisia Judaica, the Brizas, Centaureas Clemenae, gymnocarpa, and chelidissima; Chamaepeuce Cassatorum, and C. diantha; various Georads, and Leontop. In all but the naturally warmest soils, the bed for sub-tropicals should either be formed over masses of tree-leaves, with some short dung mixed with them so as to induce long-continued warmth; or failing this method of warming the soil, a considerable portion of drainage materials should be used under the soil, say to the depth of 1½ foot. If neither of these means be taken, the Solanums, Wigandias, and Ferdinandas, should not be employed.

Annals.—Stocks, Asters, Zinnias, Gaillardias, Salpiglossis, Phlox Drummondii, &c., should be planted; and if showery weather be chosen for planting these, they will give but little trouble to establish. Those annals that were sown in the borders should be thinned as soon as the seedlings are large enough to be handled.

Dahlia of all kinds may be planted, affording the ground a much of rotten manure, and a good watering.

THE ORCHID HOUSES.

By W. H. WATTS, Orchid Grower, B. Ford, Dorking.

Watering.—Plants of Angraecums, Aerides, Saccolabiums, Renantheras, Trichoglottis, Esmeralda Acunipe, Cleisostoma, Mystacidium, warm-growing Vandas, and others that do not rot in crocks and sphagnum moss only do not require much water at any season, and most of them are now pushing up leaves and making roots freely, and living upon aerial humidity chiefly; a moist state of the houses must be maintained till their growth is finished, just sufficient water being afforded them as will keep the sphagnum-moss fresh. The same remarks apply to the Phalaenopsis.

As the young growths of Dendrobium will now be progressing fast, the amount of moisture at the roots must be much increased; but as regards the evergreen section of Dendros, the plants should be kept rather on the dry side till growth has recommenced.

The deciduous Caudanthes must still be carefully afforded water, the present being a critical period with them, and if overwatered at this time the roots become discoloured, the growths spotted, and the tips of the leaves turn black.

Catasetums, Cycnoches, Mormodes, and Eulophia guineensis all require similar care in watering as the Caudanthes until re-established. The pretty Arundina bambusaefolia and A. Phippii are sending up strong growths, and should be placed where there is plenty of light, and be kept moist always. Amongst other Orchids that are grown in this house, as Erias, Bulbophyllums, Cirrhopetalums, Sarcoedidium, Megalochilum, Trias discolorum, Brassavolas, Scitacinas,

Microstylis, Bulleas, Pescatoreas, &c., they should all be copiously watered for several months to come. Plants that are growing on blocks if stunted for water during the growing season generally become smaller each year until they disappear. Instead of relying upon the syringe for watering such plants, it is better to immerse the blocks in water for several minutes.

Cattleyas and Lelias do not require water very copiously at any season, but just enough to keep the pseudo-bulbs plump, and if the plants are properly potted in the best fibrous peat and sphagnum-moss, they require as a rule to be watered only at long intervals of time, and when these materials have become thoroughly dry. It is not possible in the space of these articles to touch upon every species and variety grown in the two divisions referred to, and the amateur must try to make himself acquainted with the proper growing season of the plants he grows, so as to be enabled to afford water at the proper time.

Vandas.—Those of the anavis and tricolor sections may now be placed in a part of the Cattleya or intermediate-house, care being taken to shade the plants from the sun's rays, or they will lose some of their leaves that is desirable. Excessive flowering and much water at the root must be strictly guarded against; and rather than afford the plants a thorough application of water each time they appear to be dry, merely keep the moss in a growing condition by an occasional sprinkling from a fine rose-can. V. Amosiana and V. Kimballiana should be treated similarly in regard to watering, except that these species should have rather more light. Both will now be making roots, and any necessary re-surfacing may be carried out forthwith. The leaves of Vanda Americana are liable to be infested by a small species of scale insect, which, if not destroyed, causes much harm, and in freeing the plants of them, the operator must not bend the tips of the leaves which are extremely brittle.

Coleogyne cristata.—Re-potted plants of Coleogyne cristata and its varieties may be lightly syringed overhead several times daily till growth becomes fully active, at which time the soil should be made slightly moist, the supply of water being increased by degrees as growth progresses. For the present, the plants should be shaded from strong sunshine.

Species of Chysis which have gone out of flower will have made some amount of growth, and as many of the species commence to make roots at this time, it is a good opportunity to do any fresh potting required. For the present, these species of Chysis may be hung up in a light part of the Cattleya-house, and as soon as the new growths begin to form their pseudo-bulbs, they should be removed to the East-Indian, or other house where there is plenty of light and more heat and moisture. From now onwards, and till growth is finished, these plants require copious waterings when the potting materials have become dry.

Barkerias are easy plants to grow, and B. Lindleyana, B. Skinneri, B. cyclotella, and B. elegans, under good culture brighten up our Orchid-houses during the winter. Most of these species are beginning to grow anew, and should be overhauled. First remove the decayed sphagnum-moss, then cut away all dead roots and unhealthy parts of roots, afterwards lay the plants in new wooden rafts, upon which a layer of sphagnum-moss is first placed; the plants will grow satisfactorily when fastened to twigs of Birch, several of these being stuck into properly-drained pans or baskets, with a surface of fresh sphagnum-moss. Barkerias should be hung in a light part in the Cattleya or Mexican-house, and afforded abundance of water during the season of growth, syringing them overhead at sunny intervals at closing time. See that scale, mealy bug, and green fly do not infest them, or the growths will be stayed in development. Amongst the more interesting plants now in bloom is Cyripedium caudatum, a species sometimes observed in poor condition, which is in most cases due to excess of heat and direct sunlight, and deficiency of fresh air. The best place for a plant of this species is on the north or the shady side of an intermediate-house, where it will get abundant ventilation. About two weeks after removing the flower-spikes is the best time to repot the plant. A strong and healthy specimen may require a pot two sizes larger than the one it has grown in, which must be filled to one-third its depth with clean crocks, topped with a thin layer of sphagnum-moss. Peat and sphagnum in equal parts, with a few crocks or lumps of tufa intermingled, form a suitable compost, which should be pressed with moderate firmness around the base of the plant. C. caudatum should never be allowed to get dry at the roots.

THE APIARY.

By EXPERT.

Swarming.—It will not surprise us to hear of early "swarms" this year, should the weather continue warm. There are plenty of stocks showing promise in that direction, and if the giving of space be delayed too long, they will be difficult to control. We strongly advise novices not to "jinx" for the time when they may begin making artificial swarms. Experienced bee-keepers may find it advantageous and necessary at times to swarm bees artificially, but the amateur will find less to discourage him if he allows his bees to swarm naturally. If he wants increase, stimulate carefully, and give no surplus room, they are then likely to swarm early, and swarm often, while natural swarms are safer and better in every way than artificially made ones. It must be admitted that circumstances may arise to make it undesirable to allow or wait for natural swarming, and so we may say that, under certain conditions, artificial swarming is simple enough. Given warm weather, and two strong stocks of bees, it only requires that the queen be lifted out of the hive No. 1 with the frame of comb on which she happens to be found, and placed in the centre of a new hive, the frames of which should be fitted with foundation, or preferably frames of combs and foundation alternately. The new hive is then set on the stand previously occupied by No. 1, and No. 2 is moved some distance away to a new stand, while No. 1 takes its place on No. 2 stand. Thus the new hive gets the queen, and all the flying bees of No. 1 (this, of course, constitutes the swarm), while the adult bees of No. 2 take possession of the combs and broods of the former, raising for themselves a new queen from the brood left in the hive. If this operation is performed in the middle of a fine day, it will very rarely fail. This is the simplest and safest method of forming an artificial swarm. Should swarms have come off before the issue of our next number, they must, as already mentioned, be fed daily during bad weather. A few wet or cold days immediately after having greatly check the progress of new swarms, and it is of the utmost importance to keep them going by feeding, so long as the adverse weather lasts. Nothing should be left undone which will be of use. Very Hives, supers, syrup for feeding, &c., must be prepared ready for use. Parcels of things which have been stowed away during the winter should be examined and put in order, so that they may be at hand when wanted; in fact, now is the time to look over everything which is likely to be required both for swarming and supering, in order that make-shift appliances need not be used—and, above all, the necessity avoided for doing work in a hurry, which, as we have so often said, means doing it badly.

New Use for Surplus Pollen.—Perhaps the following use for surplus pollen may be of interest:—Having cleared a shallow frame super of some pollen-plugged cells, the refuse mass (about two handfuls) was put in a gallon of water, and heated to just below boiling-point. Then, while still hot, sugar was dissolved in the liquid until an egg would swim with part of its surface exposed equal to the size of a shilling (as in the old recipe for honey). When lukewarm, 1 oz. of yeast was added and placed in a warm room. Very vigorous fermentation set in, and after a few days the liquid was sieved and bottled. This forms an agreeable, sharp, strong drink.

From Bee Record. Query No. 974.—Salt scale about the hives for keeping down weeds. Please inform me in May *Bee Record* if salt would do for spreading round hives to keep weeds down? I mean, do you consider it would be injurious to bees? If not, I think it would be a good thing for the purpose, and it would look nice and clean, like spar. I am a reader of *Record*, but I have never seen salt-scale mentioned in your paper. T. B. C., Chesham, April 11.—Reply:—Our knowledge of salt-scale is too limited for us to say how it would answer so far as keeping weeds down about hives. There is need, however, be no fear as to its saline properties doing any harm to bees. We should rather think it would do good, seeing that bees sometimes visit objectionable places when tempted thither by saline liquids.

"THE NEW GULLIVER."—The Roxburgh Press, Ltd., will shortly issue a book, entitled *The New Gulliver, or, Travels in Atlantic*, by C. T. DARTON, being a scientific skit on *Gulliver's Travels*, or a Naturalist's Experience on a Gulliput. Naturalist rendered easy and amusing.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

Letters for Publication.—As well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction in these pages, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

APPOINTMENTS FOR JUNE.

FRIDAY,	JUNE 5	Whitechapel Show of the Royal Botanical Horticultural Society of Manchester, continuing until June 10.
MONDAY,	JUNE 7	Cambridge Horticultural and Rose Show.
WEDNESDAY,	JUNE 9	Chesham and Essex Horticultural and Rose Show (2 days). Royal Cornwall Agricultural Show, at Lestwithie (2 days).
FRIDAY,	JUNE 11	Royal Botanic Society, Lecture.
SATURDAY,	JUNE 12	Royal Botanic Society, Meeting.
TUESDAY,	JUNE 15	Royal Horticultural Society, at Drill Hall. Royal Horticultural and Rose Show.
WEDNESDAY,	JUNE 16	York Floral Fête (3 days).
THURSDAY,	JUNE 17	Lincoln Society.
FRIDAY,	JUNE 18	National Rose Society's Southern Show, at Portsmouth.
TUESDAY,	JUNE 22	Queen's Commemoration Day. Victorian Era Flower Show, at the Crystal Palace.
WEDNESDAY,	JUNE 23	Richmond Horticultural Society's Royal Agricultural Society's Show, at Manchester (6 days).
THURSDAY,	JUNE 24	Colchester Horticultural and Rose Show.
FRIDAY,	JUNE 25	Middlestone Horticultural and Rose Show. Royal Botanic Society, Lecture.
SATURDAY,	JUNE 26	Royal Botanic Society, Meeting. Royal Horticultural Society, at Drill Hall. Royal Oxfordshire Horticultural Society, Commemoration Show, Hereford and West of England Rose Society, Exhibition in the Ship Hall, Hereford. Rose and Horticultural Shows at Canterbury and Sutton.
TUESDAY,	JUNE 29	Croydon Horticultural Society's Show. Reading Horticultural Society's Rose Show. Ealing Horticultural Society's Show.
WEDNESDAY,	JUNE 30	

SALE.

FRIDAY, JUNE 11 Imported and Established Orchids, at Prothero & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—60°.

ACTUAL TEMPERATURES.—

LONDON.—June 2: Max., 66°; Min., 51°.
PROVINCES.—June 2 (6 A.M.): Max., 69°; York, Min., 45°, Aberdeen.

To all those who know the small economic value of hedgerow timber, even when felled in sound condition, the various reasons for planting it seem rather beside the mark. If we take the trees found in ordinary hedges in parts at a distance from the metropolis, these consist of a heterogeneous lot of species, but mostly Oak, Maple, Sycamore, Beech and Ash; and the trees standing without shelter have usually,

as a consequence, a compact, dense crown, commencing at from 4 to 8 feet above the hedge top, and supposing the hedge itself is 5 feet high, they have a bole of from 9 to 13 feet in height—that is of just about the height of a gate-post, or the length of cart-shafts, which is about all the uses that the boles can be put to when cut. Conceding this much, it may be asked what useful purpose is served by planting trees in hedgerows. We are sure that there are many direct evils that follow the practice, namely, the spoiling of the hedges by depriving the latter of light and the land of moisture, as far almost as the tops extend, and shading and impoverishing the land as far as the roots and crown extend, thus inflicting a direct injury to the crops in the neighbourhood of the hedge, which cannot be of advantage to either tenant or owner.

We have as a set-off against these evils, as previously stated, a lot of trees of little commercial value, and a well-wooded appearance given to the land, but which is in appearance only.

If hedgerow-timber must be planted, and at a minimum of loss to the farmer and market-gardener, the trees must be shorn of their branches, and reduced to the dreadful mop-headed specimens so common within a few miles of London—mere caricatures of trees. We believe that the pleasant, well-wooded appearance of the country can be preserved in most part by doing away with a great many of the old hedgerows, which may be of use in some cases, as affording shelter to stock in the fields, and as wind-breaks, and substituting banks of soil, and a ditch, perhaps, on one or both sides, the bank being topped by a stout wooden or iron rail, or with dwarf hurdles of iron; and in districts not hunted over, with strained iron-wire. With the disappearance of the hedges, the cultivator would get rid of a source of great expense as regards the labour required to keep them in order; and he would also be freed from those most prolific nurseries of weeds and of harbour for rabbits and birds which prey on his crops, the weedy ditches, and banks, and hedge-bottoms. Those who have experience of estate or farm-work will testify to the readiness with which a bank and ditch may be cleaned of weeds and put into good order, as compared with an old hedge having a ditch at the foot. The latter is soon cleared of its vegetation with a bagging-hook (form of sickle), but no amount of labour which the farmer cares to employ will free the hedgerow of weeds. There are some who will tell us that many of the birds found in hedgerows are the farmer's friends; be it so, but failing the hedges these birds would still find suitable nesting-places. His best friends of the hedgerows are the small carnivora—the stoats and weasels; and these would always find congenial quarters in the banks, which might in time supersede the old hedges. These banks could have their somewhat severe lines softened by planting at wide intervals small-headed trees, as those of the Crab, Thorns in great variety, Cider fruit, common Holly, Portugal Laurel, Morello Cherries, Damsons, Laburnum, Snowball-trees, Sorbus domestica (Service), Mountain Ash, Sea Buckthorn, and many other kinds of trees of small growth and moderate prices. In some localities the Weeping and common Willows, and in others Thuya, Junipers, Cypress, and other Conifers of small growth, might be planted.

The timber that is in constant demand for a variety of purposes on a farm could be grown in a much better manner, and of finer quality, on a few acres set apart in some suitable corner of the occupation; and if this were generally done by landlords and owners, the present wooded aspect of the country-side would be imparted to it equally well, or better than is now the case, besides extra cverts being provided for game-birds, &c.

DURING QUEEN'S COMMEMORATION DAY, on the 22nd inst., the Royal Gardens at Kew will be closed by order of the First Commissioner of Works. If a similar rule be observed in other public and private gardens, a small proportion only of our readers will be unable to take part in the general rejoicing.

THE RECENT TEMPLE SHOW.—In our report of this show in our last issue we inadvertently omitted to notice the exhibit of Messrs. JONES & SONS, Strewsbury. They had an extensive and choice selection of floral designs of much the same character as we frequently see from the same firm at the Strewsbury Fete in August.

TESTIMONIAL TO ALDERMAN W. H. ROGERS, J.P.—The members of the Southampton Horticultural Society, for some years one of the leading societies in the South of England, having learned that the estimable and venerable chairman of the executive committee, Mr. W. H. ROGERS, the proprietor of the far-famed Red Lodge Nurseries at Southampton, felt it needful to retire from the honourable post held for nine years by him with so much credit and benefit to the Society, resolved to invite him to accept a suitable address as a parting testimonial or compliment. The ceremony of presentation took place in the Mayor's parlour on the 17th ult., the presentation being made by Mr. Alderman BONE, a vice-president, on behalf of the members. Mr. BONE mentioned that Alderman ROGERS had been identified as a member of the Horticultural Society for thirty-five years, and during that time he had greatly assisted the shows by the large exhibits of flowers, fruits, &c., which he had made. The Society was just now in some difficulty, because of the lack of a real home for the summer shows, and the retirement of the chairman rather accentuated that difficulty, which, however, he hoped the Society would in due course surmount. The testimonial comprised a very handsomely-framed and illuminated address, which was of the most complimentary kind. To this Mr. W. H. ROGERS made a very feeling and suitable response.

ROYAL SEEDSMEN.—We understand that Messrs. DICKSON & ROBINSON, 12, Old Millgate, Manchester, have, by Royal Warrant, been appointed seed merchants to the QUEEN.

SEEDS BY THE TON.—The India Office has lately issued a very interesting report on the purchase of Carrot seed, for the purposes of famine relief in northern India, basing its intentions upon Sir EDWARD BUCK'S admirable report of October 6, 1878, "On the Use of Carrot and other Root Crops by the Agricultural Population of the North-West Provinces during Times of Severity." From this previous experience it will be gathered that this popular vegetable has been found of service as a food plant at times when the native crops have proved a failure. The quantity required to fill this enormous order—200 tons—seems astounding, and would set many a thinking as to how it could be carried out; but our leading seedsmen are so accustomed to great weights, that we are told in this report that 2,302 sacks, each nearly 108 tons, were packed, despatched, and shipped within nine days after receipt of the order, and Messrs. CARTER tell us that if there had been another steamer available within the limit of the date given, they could have despatched the whole quantity. Surely they well deserve the letter

FIG. 135.—VARIETY OF HYDRANGEA HORTENSIS: FLOWERS BRIGHT ROSE COLOUR,
AND MORE THAN TWO INCHES ACROSS.

(Shown by Messrs. James Veitch & Sons, Ltd. See Report of Temple Show, in *Gardeners' Chronicle*, May 29, 1897.)

FIG. 136.—MESSRS. SUTTON AND SONS' GLORIOSAS.

(As exhibited at the Temple Show, May 27-28, 1897. See Report of the Show, in *Gardeners' Chronicle*, May 29, 1897.)

of thanks that was sent them by Her Majesty's Secretary of State for India, as the report states, "For the energy, celerity, and comparative economy with which this large exportation was effected."

PLANT-GROWTH AND THE WEATHER.—In a very interesting paper on the effects of the weather upon vegetation read at Bradford, by Mr. JOHN CLAYTON, on March 1 of the present year, the author made some interesting observations relating to the increased girth of trees in proportion to the favourable character of the weather. Careful observations of the weather were duly chronicled, but what seemed suitable weather was not always followed by corresponding results in the expansion of trees. However suitable the weather or season might be, if the trees were flowering or fruiting freely, there would be only slight increase in girth; also the year following a heavy fruitage, the growth would be found to be little, though the conditions were satisfactory. Thus it became apparent that the mere girthing of trees would not give the measure of the suitability of a year's weather. If the weight of the Wheat crop be taken as a standard to judge the weather by, it would be found equally faulty, for the influence of the previous season on the seed-corn affects to a great extent the crop of the year, nor is it possible to find a reliable standard in any other form of vegetation.

"DIE NADELHOLZER," Von Dr. CARL FRIEDRICH VON TUBERF (Stuttgart, Eugen Ulmer), pp. 164, 100 illustrations. This is a treatise on the Conifers which are hardy in central Europe. The arrangement of the genera is the same as that adopted in ENGLER & PRANTL'S *Natürlichen Pflanzen Familien*. Each species is described, and many of them are figured. The illustrations are excellent, and constitute the most valuable portion of the work. The *Report of the Conifer Conference*, one of the most valuable treatises on cultivated Conifers, appears to be unknown to Dr. Von TUBERF.

HEMEROCALLIS FLAVO × MIDDENDORFI. — Dr. CURSER, of Bale, obligingly sends us an account of the curious hybrid which has appeared in his garden at Liesthal between the two species above-named, both of which are cultivated by Dr. CURSER. A resemblance to *H. Middendorfi* is shown in the leaf, colour of the flower, bracts, and short flower-stalk. The inflorescence and length of the tube accord more nearly with *flava*. The long cymose inflorescence is raised on a short scape. A coloured illustration is given in the *Transactions of the Natural History Society of Bremen*, 1897, xiv., H. 2.

SMITHSONIAN REPORT.—The annual report of the Smithsonian Institution at Washington is now published up to July, 1894, and contains, as usual, a considerable amount of most varied information, upon which we can but briefly comment here. In addition to matters immediately connected with the management and economy of the Institution, we find papers on "Astronomy," the "Waste and Conservation of Plant Food," "Weather Making, Ancient and Modern," "Physical Condition of the Ocean," "Ants' Nests," "Migration and the Food Quest," and other scientific subjects, treated, some technically, and the remainder in a more popular manner interesting to general readers as well as to advanced students.

MR. JAMES BAGNALL.—The author of the *Flora of Warwickshire* has accumulated material for the production of a flora of the adjoining county of Staffordshire; and now that, as we understand, he will have more leisure to devote to his botanical labours, we may look forward to as critically good a flora as that of Warwickshire.

LANDSCAPE GARDENING AS AN ART.—In *The Country Illustrated Monthly Magazine* for May, in an article on Professor SARDENT'S beautiful suburban residence in Brooklyn, Mrs. G. VAN RENSSLAER makes the following remarks:—"All the science, all the patience in the world, will profit a landscaper-gardener little if his sense of beauty has not been developed by the persistent observation and study of

beauty both in Nature and in Art. An artist in gardening is not born ready-made, or fostered by scientific acquirements, any more than an artist with paint or chisel. On the other hand, all the artistic instinct, all the artistic training in the world, will not make a man a good landscaper-gardener unless he has much scientific acquaintance and much practical experience with plants." After showing how these general remarks bear special reference to the subject of her paper, the author says further that:—"Landscape-gardening is a genuine art, an independent art, a very different art, and one which demands much knowledge of other than artistic kinds. No superficial amateur, and no professional man of one-sided training, can create a really fine country place of a highly-civilised and polished sort, perfectly adapted to the needs and tastes of its owners, entirely appropriate to its situation, completely realising the natural possibilities of its site, displaying the full resources of modern horticulture, delighting the eye with pictures of the most diverse kinds, and satisfying it by their combination into a harmonious whole. The genius of a country-place like Holm Lea requires the mind of a scientific botanist, the hand of a practised horticulturist, the heart of a lover of Nature, the eye of a trained artist, and, besides all these, the beautiful patience of Job."

THE TESTING OF NEW VARIETIES.—A recent number of the *Revue Scientifique* has a note, not merely upon the value of new varieties of economic plants, but upon the necessity for thoroughly testing these before publishing authoritative statements with regard to their properties and capabilities. To quote M. LIEBSCHER, whose experiments in Germany are detailed in the *Experiment Station Record (Illinois)*, "it is only after a range of seasons and cultivation treating with the same variety, that a definite result can be attained;" and it is only after comparing different varieties for years, that it is possible to assign to them a relative position as regards their yield, or from any other point of view. Thus, in Illinois, nine of the principal varieties of *M. lize* were subjected to a continuous trial for eight consecutive years. Each season a position was assigned to each variety according to the abundance of the yield (under identical cultural conditions, &c., of course), and at the end of the eighth year they were classified according to the total results. The following table includes the yearly results: the first column gives the name of each variety, the others the relative position of each variety in the year under consideration, the last column their places according to the total of the several results:—

Variety.	1888	1889	1890	1891	1892	1893	1894	1895	Average Height Years
Loaming ...	2	2	3	4	3	7	1	4	1
Burr White ...	1	4	2	3	4	2	2	5	2
Clark Inroquois ...	9	3	6	5	2	4	8	1	3
Champion (White Pearl)	8	1	1	1	6	1	4	6	4
Legal Tender ...	3	5	5	8	7	8	5	4	5
Murdock ...	6	8	4	6	9	6	7	3	6
Edmonds ...	4	6	7	7	8	9	6	2	7
Riley Favorite... ..	5	7	8	9	1	3	3	7	8
Golden Beauty ...	7	9	9	2	5	5	9	5	9

It will be noted that, in the first year, for instance, the varieties which now occupy the third and fourth places were the poorest of all; and that which is on the average first fell one year into the seventh rank, having but once occupied the foremost position, while No. 4 was four times found in the first place. This table is instructive, and the conclusion to be drawn from it evident. It is only in time and by means of successive trials that reliable conclusions can be formulated.

"FLORAL ALBUM OF CONFERENCE DAFFODILS.—Mr. HARTLAND, Tulip and Daffodil grower, Cork, Ireland, is publishing his *Floral Album of Conference Daffodils*, second edition, 1897, commemo-

rative of the Victorian Era, and containing some fine additions to an already beautiful work of art. It will also contain a Jubilee poem by the proprietor, entitled "Sixty years of a Starlit Age," illustrated with likenesses of the Queen, Watt, Stephenson, Edison, Röntgen, and others. The work is copyright, and limited to 250 copies.

THE DEVON AND EXETER GARDENERS' ASSOCIATION.—The summer excursions of this Association will take place on Wednesday, July 14. By permission of the Earl of Mount Edgcumbe, the party will, an hour after arrival at Plymouth, to permit of lunch being partaken of, proceed to Mount Edgcumbe, where, under the guidance of Mr. RICHARDS, the Head Gardener, the beautiful grounds and gardens of that famous estate will be inspected.

"THE JOURNAL OF THE ESSEX TECHNICAL LABORATORIES" for March and April contains articles on the use of Bordeaux Mixture, in which it is shown that a largely increased crop results from spraying, and that an increased food-value is noticeable in the tubers from the sprayed portion of the experimental plots. The average increased yield, after spraying, amounts to 1 ton 5 cwt. per acre, at an average price of £2 per ton, the cost of spraying being computed at 15s. per acre. A study of *Dendrobium nobile* comprises the minute anatomy of the whole plant, as well as some useful cultural details. We would point out the desirability of instituting comparative studies of this character. The structure of the leaf in this order affords the most remarkable variations.

THE FRUIT PROSPECTS at the present time are by no means reassuring. The general experience has been an abundance of bloom upon most kinds of hardy fruit trees; but subsequent weather has had such a destructive effect upon the blossoms that a considerable proportion has fallen. *Pears*, so far as we have observed, are exceedingly rare, and *cherries* also. *Pears* are not more than a light crop, whilst *Apples* will possibly be rather more numerous. When visiting Ruxley Lodge recently, the residence of Lord FORLEY, at Esher, we were pleased to see that an excellent crop of *Peaches* is likely to be obtained from the walls outside. At present the trees carry a splendid crop, and this after much thinning, and the trees and foliage being in capital condition, there is little probability of injury after this date. Mr. MILLER, the gardener there, is very attentive to the needs of his *Peach* and *Apricot*-trees out-of-doors, and rarely does he fail to obtain a crop, though *Apricots* are not plentiful this season. The *Peach*-trees are removed from the walls each winter, and by means of stakes are kept as far from it as possible until the swelling of the buds compels them to be trained. By this old but excellent practice the flowers are retarded until the worst of the frosts are past, and by the use afterwards of ordinary fishing-nets or similar material, danger is reduced to the least minimum possible. The fruit-trees inside at Ruxley are looking well, and *Vines*, *Peaches*, *Nectarines* and *Figs*, promise excellent crops of fruit.

EDUCATION.—Last month Sir JOHN GONSR spoke at Girtton on the question of education in rural England, and told his hearers that they could not successfully compete in agricultural products with Continental nations, who sent many things to England which ought to be grown at home. Denmark at the beginning of this century was one of the poorest countries in Europe, and to day it is one of the richest, because Denmark supplies the English people in manufacturing towns, and even in country districts, with butter, eggs, and bacon, which Englishmen ought to produce themselves. The people of Denmark attribute their prosperity to the education received in the high schools, where every boy and girl is kept until fourteen years of age; besides this, there are winter and evening schools in that country, where any one can study until he is thirty. Sir JOHN also pointed out that the children in rural France were kept at school in the same way, and that, in addition to the money expended for general education, France devoted a million dollars a year to special teaching in agricul-

ture and horticulture. Instruction in these arts, he said, was obligatory even in primary schools in the country, and all over France they had higher schools, schools of practice and itinerant teachers, and experimental plots at convenient distances, where demonstrations were given. There are more than 3300 of these experimental gardens in France. Sir JOHN thought it was a mistake to endeavour to fit country lads for third-class clerks-hips in the cities instead of fitting them for country pursuits, since the restoration of prosperity in the rural districts depends upon the intelligence of the country population which furnished the workers. *Garden and Forest.*

WREATHS AND GARLANDS.—Mr. TALFOURD ELY read a paper at the Archaeological Institute on May 5, on "Wreaths and Garlands," with especial reference to Greek and Roman usages. He pointed out that the English limit the use of wreaths to funeral purposes, whereas among the ancients the wreath was a sign of feasting and joy. In classic times, the dead were, indeed, crowned, but crowned as still partaking of the pleasures of this world, bodily pleasures being held in nowise incompatible with religion. Religion originally prompted the use of the garland, which may have been connected with the widespread belief in the supernatural powers of trees and plants. Wreaths were employed as hangings to assuage headache resulting from debauch; and certain plants, as the Myrtle and the Rose, were believed to exercise a prophylactic power against the effects of wine. The Greeks, too, were fully sensible of the beauty of flowers, and floral decoration plays a great part in Greek poetry, from Sappho downwards. Among the early Romans, on the contrary, the use of wreaths in public was strictly limited to religious functions and marks of distinction connected with services performed to the State, such marks of distinction being largely derived from the Etruscans, who made great use of wreaths. In Greece the simple wreath of Olive, &c., as a reward for athletes, superseded the prizes of intrinsic value offered in heroic times. In the fifth, and still more in the fourth century, crowns, usually of gold, were awarded to successful statesmen or warriors. Wreaths of Laurel, Myrtle, Vine-leaves, or flowers were commonly worn at Symposia, and are thus represented on vases. For the most part, of course, these wreaths have perished, but some have been preserved in Egypt. The manufacture of garlands gave employment to many, and its processes may be seen depicted in several Pompeian pictures. The gold crowns were frequently modelled in the form of leaves, as Ivy, &c. Other materials for wreaths were wool and artificial leaves, and flowers of horn or silk. Though the origin of the use of wreaths is lost in antiquity, its primary purpose was probably religious; and the practice of crowning the dead may have arisen from the deification of ancestors.

CAIRO FLOWER SHOWS.—A horticultural show will be held, it is announced, in the Esbekieh Gardens, Cairo, from January 14 to 16, 1898. The exhibits will include flowers in pots, foliage-plants, cut flowers, and bouquets, window and table decorations, exhibits (pot-flowers, plants, fruit, veg. tables, bulbs and seeds) sent direct from Europe; fruit, vegetables, preserves, and pickles. Various awards will be made in these several divisions, and intending exhibitors can apply for "forms of application for space" at the Hon. Secretary's office, in the grounds, before December 29. We have also received intimation of a Chrysanthemum show to be held at the Continental Hotel, Cairo, November 19, 1897. The entries will be classed as follows:—Pot-plants, six of each variety; pot plants, twelve heads of each variety, and as Chrysanthemums, Japanese, incurved, dwarf, and new variety respectively. Application for space should be addressed to the Hon. Secretary-Treasurer, W. WILFRED CAREY, Esq., Kasr-el-Douhard, Cairo.

THE SWANSEA HORTICULTURISTS associated themselves together about a year ago for the purpose of meeting during the winter months to hear and discuss lectures upon horticultural subjects. They

are now turning their attention to exhibiting, and a schedule to hand informs us that the Swansea Horticultural Association will hold its first annual exhibition on August 26 next. Thus far, so good; and we hope that the society will continue the debates, for which it was originated, and not be led to throw all its energy into promoting exhibitions, as some others have done. The president is Sir J. T. D. LLEWELYN, Bt., who is well known as an enthusiastic patron of horticulturists. The schedule is sent us by Mr. T. FOSTER, one of the hon. secretaries.

INJURY TO THE VINE IN FRANCE.—A Reuter's despatch from Auxerre states that the Vine, fruit, and vegetable crops in the city and district have been ruined by frost, the damage in the department of the Yonne alone being estimated at 20,000,000*fr.*

FROZEN CAPE HEATH.—The *Norman* brought home, says *The African Critic*, an immense wreath, composed of Cape Heath, for the Emperor of GERMANY. It was frozen in a solid block of ice, and the case which contained this treasure was so gigantic that the *Athenian* was unable to take it into her ice-chamber. It was sent on to Hamburg.

UNIQUE CLOCK GARDEN.—A correspondent of the *New York Herald* writes as follows from Berkeley, California, on May 8:—"A clock garden, whose flowers will tell the time of day, is being planned by Instructor H. A. OUSTERHOUT, of the botanical division of the University of California. He proposes to cultivate such a garden on the University grounds, arranging the plants in dial form. The hours and half hours are to be indicated by the successive opening and closing of buds. The work of producing a clock garden will be a long task, as it has never been attempted in California before, and a great deal of experimenting will be necessary to find out just what flowers should be put around the circle to indicate time. The garden will be the only one of the kind in the United States. 'By getting the right varieties of flowers we can mark all the hours and some of the half hours throughout the day,' said Mr. OUSTERHOUT, in describing the projected botanical curiosity. 'The flowers would be arranged like a clock, and in the early morning they would begin to bloom—the different varieties at different periods, according to the light and heat. Gradually the opening of flowers would extend around the circle, until at night the circle would be all in bloom. The first garden of the kind was at Upsala, Sweden, by the Botanist LINNEUS. There is also one in Paris, and efforts have been made to cultivate them in the Eastern States, but owing to the elements they have not been very successful. I think the Californian climate is suitable for such an experiment. The questions that remain to be solved are as to what flowers are best here, and at what time of day the different varieties will bloom here.'"

M. MOTTET has been appointed manager of the experimental grounds of MM. VILMORIN, ANDRIEU & Co., at Verrières, near Paris, in the room of the late M. VERLOT.

THE NATIONAL CO-OPERATIVE FLOWER SHOW is fixed for August 20 and 21 next, and, as usual, it will be held at the Crystal Palace. From the schedule it appears that the prizes are increased to £350 in cash, besides Gold, Silver, and Bronze Medals, and other awards. There are to be fourteen judges, including Mr. A. F. BARRON, Mr. COMBER, Mr. R. DEAN, Mr. T. W. SANDERS, and Mr. D. T. FISH. Mr. Geo. WAUGH will again be Hon. Director of the show, and Mr. Ed. OREN GREENING as Hon. Secretary. Copies of the schedule may be obtained from the Hon. Secretary, at 3, Agar Street, Charing Cross, W.C.

VALUE OF A NITROGENOUS MANURE.—Mr. F. J. R. CARULLA, Chairman of the Nottingham Section of the Society of Chemical Industry, has just issued a paper, in connection with the Iron and Steel Institute, on the "Agricultural Value of Sulphate of Ammonia from Blast Furnaces." The writer deprecates the lack of positive knowledge evinced by farmers on the subject of the properties and values of various nitrogenous manures, and therefore is

desirous of contributing some reliable information on the subject. Mr. CARULLA is a champion of sulphate of ammonia, claiming that nitrate of soda owes its popularity as much to continual recommendation as to intrinsic merits; that the former substance (sulphate) is equally valuable but less widely known; and also that, being formed largely in blast-furnaces, ironmasters should take every opportunity of insisting on the merits of it as a manure, and be ready to dispose of it on terms mutually advantageous to themselves and to agriculturists.

ORCHID PRICES.—We are informed that the plant of *Odontoglossum crispum* var. *heliotropium* awarded a First-class Certificate at the meeting of the Royal Horticultural Society on April 27 last, was sold by auction on Friday last for 135 guineas.

FLORAL DECORATIONS AT THE ALBERT MEMORIAL.—The First Commissioner of Works having given his consent to "a floral decoration of the base of the Albert Memorial in Kensington Gardens for June 22," we are informed that a committee is being formed to carry out the scheme. I would suggest that an appeal be made to the public for the gift of flowers and shrubs, in pots, for this purpose, such gifts to be subsequently distributed amongst the London hospitals, as a fitting memento of the Diamond Jubilee Celebration. *S. G. CUTLER, 10, FOSKETT ROAD, S. W.*

PUBLICATIONS RECEIVED.—From the University of Illinois Agricultural Experiment Station, Urbana, Bulletin No. 47 (March), *Broom, Corn-smut*, dealing with the nature, effects, and treatment of this pest; and also Bulletin No. 48 (April), *The San Jose Scale in Illinois*, an account of one of the most pernicious and generally injurious insect enemies, whose gradual and sometimes unperceived attacks sometimes ruin whole orchards (in America) before it can be checked.—*Annual Report on Government Gardens and Parks in Mysore for 1895-6.* We learn from this that during the past season "the weather was seasonable for field and garden crops," and that progress and improvement were manifest in both the management and condition of the gardens.—*Books of To-day, and the Books of To-morrow*, by ARTHUR PENDENTS, May.—*The Book and News Trade Gazette*, May 8.—*The Bee-Master*, May 15; the first number of a new periodical, to be published fortnightly, and devoted to the fascinating and often remunerative bee industry.—*Mothers and Daughters* (A. W. HALL, 28 to 32, Hutton Street, Whitefriars), formerly a monthly, will in future appear as a weekly publication. The first of these parts is dated May 29, and known as the Queen's Birthday issue. It is appropriately accompanied with a portrait of Her Majesty (25 by 20 inches), which forms an acceptable supplement. A smaller picture appears on the cover, and this, as well as the larger plate, are both pleasing and faithful likenesses.—*Cassell's Saturday Journal* is full, as usual, of interesting items.

NURSERY NOTE.

ORCHIDS AT MR. W. BULL'S, KING'S ROAD, CHELSEA.

We found here, on the occasion of a recent visit, the annual display of Orchids in the long, narrow, span-roofed house at the north side of the Palm house. The effect was but little dissimilar to that which Mr. Bull has delighted his patrons for some ten years past, and which never seems to pall on them, or fails to interest them. The scene reminded me of the recent display of these plants at the Temple gathering, but consisting on each side of the house of two banks of flowering-plants. The view presented was observed at a glance from one end to the other, and there was, moreover, the advantage of greenery of various sorts, that was absent at the Temple, to act as a foil to the mass of colour. It may be stated that the effect is obtained chiefly by the abundant employment of *Miltonia vexillaria* in white and all shades of pink; *Cattleya Mossie*, C. Meudeli, *Dendrobium*, *Cymbidium Lowianum*, *Odontoglossum*

crispum in rich variety; *O. citrosimum*, with numerous *Masdevallias*, *Cypripediums*, *Cymbidiums*, *Epidendrum*s, and *Lælia purpurata*.

One of the finest of the *Odontoglossum crispum* noted was one rejoicing in the cognomen *stupendum*, individual blooms of which measured 3½ inches across; the segments of the flower are of great width, prettily crimped and of much substance. Several other *crispums* were noted which had excellent points, but none equalled this grand variety. Differing greatly from the preceding variety is *O.*

next comes *C. Mendeli formosa*, a handsome variety, whose lip is of a pale tint of purple. *Cattleya Mossii* and *C. Mendeli* abound, nearly all being striking in some particular; *Lælia purpurata*, in a variety of forms and of colour, is also plentiful, indeed, few Orchid nurseries can furnish such fine *Lælia purpurata*, and so well cultivated as the one under notice. *L. p. versicolor*, a not very large specimen, but unique as regards its tints, had a very high figure placed upon it. The beautiful *L. p. bella*, white in all parts of the flower excepting the lip,

species of *Cologne* noted were *Dayana* and *Masdevalliana*, both with pendulous racemes of dull-coloured flowers.

Masdevallias were numerous, both in those more strictly decorative species, and others of interest chiefly for the minuteness of their flowers and quaintness of their forms. We may mention *M. severa*, *M. Chinera Winniana*, *M. e. Roezlii*, *M. peristeria*, and *M. Chelceiensis*.

A form of *Cymbidium Lowianum* was remarked in which the sepals and petals have much darker tint:

FIG. 137.—GROUP OF HARDY TREES AND SHRUBS.

(Exhibited by Messrs. Fisher, Son, & Sibray, Sheffield, at the Temple Show, May 26-28, 1897. See Report in *Gardeners' Chronicle*, May 23, 1897.)

cuspidatum platyglossum, with its stellate form of flower and brown spotting on a yellow ground colour; a form of *O. Ruckertianum* of much beauty, and differing from the type in the suffused pink ground and the wider segments; similarly differing from the typical form in its ground colour is *O. citrosimum* concolor, of which several examples were observed. A good plant of *O. hastulatum*, with fine purplish-brown cross-barring, on a creamy-white ground, was noteworthy; as was likewise one of *O. nulus crotatum*.

Of *Cattleyas Schroderae* var. *Empress* was a striking example, of the faintest lilac tint with the orange blotch in the throat traversed with crimson lines;

which is of a very pale shade of purple, would claim a host of admirers; *L. p. fulgens*, with lip of rich tint, would appeal to others.

Among *Oncidium*s may be named *tetrapetalum*, a small plant furnished with a small spike bearing five flowers of a uniform pale mauve tint, took the eye at once; as did also *O. pulchellum*, which has smaller flowers, the colour of which is white tinged with lilac. *O. papilio* we always expect to see in its place before the mirrors. A splendid mass of *Odontoglossum macranthum hastiferum* was remarked. A plant of *Cologne speciosa major* presented a pretty study in different shades of brown, as also did *C. pandurata* in light green and black. Other

on the upper surface than those of the type. The handsome and strange-looking *C. tigrinum* was in evidence; as was *Pleurothallis ornatus*, whose minute brown flowers possess pendulous fringes of white hairs.

The floriferous *Thunia Winniana*, the singular-looking *Nanodes Meduse*, the showy *Epidendrum Wallisii*, *Brassia maculata*, which differs somewhat from, and may be said to be an improvement upon, *B. verrucosa*, several *Dendrobium*s, including *D. infundibulum*, *D. i. Jamesianum*, and others of this species, differing in the colouring of the patch in the throat, it being orange in some, lemon in others, &c. *D. transparens*, *Trichopilia tortilis virguldii*, whose

throat and lip are of pure white. Of *T. tortilis* there was some variety, the more marked features, however, being the colours of the twisted petals and sepals. A plant of *Scuticaria Steelii* on a raft had one expanded blossom, and a plant of *Chylis bracteosoma* had several on a short spike. Plants in flower were remarked of the rare *Odontoglossum Reichenei*, the still rare *Vanda Parishii*, V. P. var. *Mariadoni*, *Aurites Lindleyana*, A. Houletii, and A. *Feldingii rubrum*, a somewhat scarce plant; A. *ampullacea* var. *Moulneensis*, with short spikes of rich purple and crimson-coloured flowers; *Epidendrum Frederici Guilleimi*, whose corymbs of rose-purple flowers stood up conspicuously among other plants; *Odontoglossum nebulosum parvum*, *Cattleya bulbosa*, and *Oncidium phymatocolum*.

This unique collection of Orchidaceous plants will be open to inspection during the entire London season, the interest of the beholder being sustained by the addition of fresh plants from the storehouses of the nursery.

HOME CORRESPONDENCE.

DARWIN TULIPS.—Is it true that these so-called "Darwin Tulips" were raised by Myseher Krelage, as stated by your correspondent, "D.," on p. 341 of the issue for May 22? I am led to ask this question, because, just at present, evolution is "in the air," so to speak, and we must be careful not to overshoot the mark. Here is exactly what "D." says:—"The raiser was Mr. Krelage, the well-known bulb-grower, who, having evolved this beautiful section from out of others, by intercrossing and hard selection, feeling that the section presented an admirable illustration of the process of evolution, named them Darwin Tulips, in honour of the great apostle of evolution." That all the statements made in this paragraph are true I doubt very much! What proof has "D." that this strain of Tulips was raised or evolved "from out of others" (*sic*), by either intercrossing or hard selection? Will "D." or Mr. Krelage kindly explain? P. W. B.

THE PEACH CROP IN PEMBROKESHIRE.—As regards the state of the Peach-trees on walls out of doors at the present time, it is such, that in many parts hereabout the crop of fruit will be very scanty where there is no efficient protection from glass copings, shutters, or heated walls. The damage has not accrued from the severity of the frosts that have visited us, as from the harsh winds and the showers of hail, and snow and rain which have prevailed nearly every day since the blossoms began to expand. This year the Peach blossom began to expand earlier than usual, owing to the absence of frost; but had the foliage become blighted from the comburent effects of cold easterly and northerly winds. When once the leaves are thus crippled, they become liable to infestation by various insects that prey on their juices, and some long time elapses ere the trees are restored to health, no matter how skillfully they may be treated; and it often occurs that the grower is accused of giving them improper treatment, but it is not always possible for the grower to strive successfully against the weather; and I can truly say that a worse spring for the grower to contend with has not occurred for several years past. W. Crevell, *Pembroke, Pembrokeshire.*

PROGRESS OF THE CYCLAMEN.—On this subject a few facts and personal recollections may be of interest. Fifty years ago *Cyclamen* were mainly confined to C. *Comm.*, C. *europæum*, and C. *alepicum*; this last, which had petals strongly reflexed and of delicious scent, I take to be the original *C. persicum*, a name generally given to species from Cyprus, but the record has become blighted from the comburent effects of cold easterly and northerly winds. It is well known that the Mediterranean littoral and islands abound in *Cyclamen*, but are not its exclusive home. I have seen some on the high Swiss Alps, at an altitude of 6000 feet; and from Barbary I had one called *C. africanum*, its chief feature being the enormous size of its bulbs, which would have made a great sow-bread repeat; the flowers being of no particular merit, its cultivation was discontinued. *C. venustum* and *C. hederifolium* may be considered British species; thus, Europe, Asia, and Africa contribute to this interesting family, and may we not include America in a first cousin, *Dodecatheon Meadii*? I come now to the present large-flowered varieties. In the fifties and

early sixties, the most complete collection of *Cyclamen* to be seen at the nursery of Messrs. E. G. Henderson & Son, St. John's Wood (now part of Lord's Cricket Ground). In their service was James Edmonds, a cultivator *facile princeps*, who subsequently went into business on his own account at Hillingdon, near Uxbridge, whence, up to his decease a few years ago, he produced and exhibited from time to time most of the finest varieties now to be seen, and to him should be assigned the place of honour. *Palmarum qui nescit ferat*. The best strains are still grown in this neighbourhood, though cultivators elsewhere are making rapid strides. My own opinion is that *C. graudiflorum* vars. proceeded not from *C. persicum* (*alepicum*), but are developments from *C. latifolium* of Greece. Careful cross-fertilisation, and above all the cultivation of natural "sports," may produce startling results. The embossed-leathered variety of Messrs. High Low & Co. is an elegant novelty. S. A., *Hartston.*

RENAISSANCE OF THE HOLLYHOCK.—Having read the remarks of your correspondents "D. T. F." and "D. L. M." on the above subject, may I ask seriously if they are poking fun at us? Is *Puccinia Malvaceae* a thing of the past? It is banished from Scotland, it is much in evidence in England. For ten years I have been trying to get some healthy Hollyhocks, but although I have bought seed and plants from all the best sources in England, and we are on a cool soil 450 feet above sea level, still the Hollyhock disease prevails. I tried the Bordeaux Mixture without any good results. May I ask if this another case like the re-discovery of Garibaldi Strawberry in that little garden in Edinburgh? I may say that I have been ill, and I send my *Gardener's Chronicle* to my sons in Australia, otherwise I should have written earlier. We are much obliged to brother Scots over the border for looking after the Pansies, and for the fine race of *Violas* they have raised for us, and if they are doing the same for the Hollyhock, I wish them good luck in their efforts. In speaking of Pansies, you never see such Pansies now as Thompson of Iver, Turner of Slough, Bragg of Slough, and the Hates of Drayton, father and son, used to grow in 1855 and 1854. About the latter date a fungoid disease overtook them, and the thing was over in England; and with respect to Hollyhocks, in 1853 I was helping a grower of Hollyhocks for show when a lad, and I recollect handing up to a tall man on a tall pair of steps, canvas shades about 5 feet long, made on hoops, to shade the show spikes, about 4 feet 6 inches long, and every bloom perfect—the main stalk was at least 16 feet high, the plants had, as a rule, five strong stakes, like hop-poles. Of late years I have not been able to grow a starveling 6 feet high, that is, not with any degree of beauty. Before we get on with the renaissance, we must remember the past. I think it was in the autumn of 1853 or 1854, at the same place, a long range of pits were filled with cuttings in small pots, about 30,000; the disease came and took them, and I do not think a dozen were saved. Of course, at that time fungoid diseases were not understood; it was known a disease was there, but chemical remedies were not tried. Previous to that Hollyhocks would strike like weeds, and the same disease is with us to-day; if the men of the renaissance can name a cure, then they are worth reading. R. M., *Newbury.*

TWO GOOD WINTER TOMATOS.—Perhaps some apology is needed for introducing the subject of Tomatos, after so much has already been written in respect to the peculiar merits of varieties. Knowing, however, that there are establishments where Tomatos are required almost daily throughout the year, is my excuse for recommending to the readers of the *Gardener's Chronicle* the varieties "Laxton's Open Air" and "Sharp's Plentiful" as being the best I know to produce fruit during the winter and spring months. In the first place, I ought to mention that I do not receive the seed direct from the nurseryman, but they were given to me by a neighbour under those names; and not having grown either of the varieties in previous years, I am unable to vouch for the correctness of the names. I have enclosed a few fruits of each variety for your inspection, not because ripe Tomatos are a novelty at this season, but more for their correct nomenclature. The corrugated fruit is we believe correctly named Laxton's Open Air, the other is one of the Perfection type, and may or may not be Sharp's, these being alike in form and colour. In 1891 the seed was sown in the end of May, 1891, and the plants afterwards shifted on, and potted into their fruiting-pots, i.e., No. 5 or 11-inch pots, in the usual manner, kept out-of-doors till the first week in the month of October, and then placed in a light,

airy, three-quarter-span-roofed house. The plants at that time were carrying from six to eight clusters of fruits, some of which were beginning to ripen as shown by the change of colour. A few more trusses of fine bloom set before the end of the year, but from that time till the end of the month of February, not many flowers were fertilised. From that time, however, the plants began to produce large clusters of bloom, which set, and the fruits grew fast and ripened quickly. An important point with us is to have ripe and ripening fruit during winter, which can only be secured from strong, not so sappy plants, carrying six or eight trusses of fruit, the earliest of which are changing colour by the beginning of October, and growing them in such a kind of house as that described. The stem of each plant should be trained close to the roof, but the leaves not touching it, the temperature being kept at about 55° till the beginning of April. The fruits at this degree of warmth are slow in ripening, and the supply is in consequence much prolonged. Geo. Woodgate, *Rollston Hall Gardens, Burton-on-Trent.*

A GOOD EXAMPLE.—The question of the hours of labour for gardeners crops up from time to time, and the tendency now-a-days is to recognise the fact, that compared with many other callings, gardeners are hardly dealt with in this respect, and this is quite as pronounced in the numerous trade establishments as in private gardens. In the case of nurseries, the provisions have for a long time set an example to London, by curtailing in many instances the hours of labour on Saturdays, and now it is a pleasure to record the fact that Messrs. J. Veitch & Sons on Saturday, May 29, marked the commencement of a new era by closing their establishment at 4 o'clock. Our Royal Family are well known to take much interest in the working portion of the community, and to the other London nurserymen, particularly those who make a public display of the royal arms, we say, "go thou and do likewise." J. S.

FRUIT-TREE GRAFTS FAILING TO GROW.—I have an unpleasant experience of this occurrence this year. I have one bed of about 10,000 Myrobalana stocks, all headed down at one time. My foreman, who is considered a good hand at his work, and has had thirteen years' experience with me, started grafting one side of the bed with Monarch; my son began the other side with the same sort. There was no difference in the grafts, as they were all grafted by a third person, and one grafted helped himself out of the same box. Those done by the foreman are very bad—not half of them living; while those done by my son are growing splendidly, with scarcely one failure. There is no doubt one operator was more particular that the graft and scion should properly fit, and that those who tie and pitch-in have done their work well; for unless the latter is properly done, success will not follow, however well the graft may be put on. The conclusion I have come to is, that if only one person had grafted the bed of Myrobalana, I should have been the same way of thinking as "Northampton" is, namely, that the cold seed bed lasting so long was the reason for the failure. *Acot.*

—I have read the interesting note on this subject by a nurseryman in a recent issue of the *Gardener's Chronicle*, and am not surprised that some grafts of fruit-trees have failed to grow in some parts of the country, for a graft of any kind exposed to the harsh winds of the past two months was sure to suffer much or little, according to the amount of exposure. In this district (Slough) the grafts of the Plum are fairly good, those of the Apple about three-fourths are alive; the Cherries are fairly good, *Acaecis* very bad; *Pyrus* bad, and *Pruinus* fairly good. I may state that we have a much better percentage of grafts where grafting-wax was used (Russian tallow and resin) instead of clay. A. R.

JANCAE HELDREICHI, ETC.—This difficult subject is now in flower, and as it has been very generally lost, and has practically disappeared from the trade catalogues, it may be worth while giving the conditions which have led to success. I think they are moisture and drainage. I began by putting the plant under the usual *Tanacetum* conditions—rocks in half shade and horizontal position. The result was gradual wasting away, ending in death. I noticed, however, that no matter how curled up and withered the poor thing was, a shower of rain or a good watering over the root had for a time a magical effect, plumping the plant out to apparent health. Evidently it was far more of a moisture-lover than

Ramondia. So, having the luck to get a second plant, I put it in peat amongst stones on a steep slope in the bog; and on the top of the bank above it I constantly have a little water running. This penetrates through the peat to the roots of the plant, and then drains still lower, when I stop the flow. Under these conditions the plant flourishes, and has now two flowers more or less like a *Pinguicula*. On the same bank several plants of *Schizocodon soldanelloides* are growing. The leaves seem to me even more beautiful than those of *Galax* or *Shortia*. The plants have gone without protection through two winters, but they have both been mild ones. Can any one do any

burn flower garden, the many fine trees in the park and on the estate generally, and the remains of the old avenues, planned or planted by Le Notre, link Arniston closely with the past, while abundantly satisfying the modern wants of the universally respected family of Dundas, one of the most honoured names in the county. D. T. F.

TREATMENT OF SPRING-FLOWERING BULBS.—Why not leave them alone? Perhaps no garden is more completely crammed with bulbs of all sorts than our own, for all the beds, the herbaceous borders, the odd places under the hedges, the kitchen garden,

alone the better they like it. At the present time we have several old strong clumps of Tulips growing up in the middle of a walk—more power to them, we let them grow and walk round them. The best way to treat bulbs is to leave them alone, and not waste time in digging them up and spoiling them. We have carried out this system for the last six years, and all who see the result go and do likewise. The beds are marked up, and any bulbs disturbed are quietly put back again. We have tried the digging up, drying, and replanting, and it is a diurnal failure. *Thos. Fletcher, Grappenhall, Cheshire.*

PTERIS AQUILINA, OR BRACKEN, ITS PROPAGATION AND DESTRUCTION.—Several of your correspondents have recently written on the above subjects, notably "D. T. F." p. 349 and previously. I have no wish to enter into any controversy on the subject, but it seems to me that the chief difference between your learned correspondents and an ordinary gardener is this. Judging by the advice given, your correspondents evidently wish to make work, whilst an ordinary gardener tries to get the work done as cheaply and as expeditiously as possible. For instance, one or two of your correspondents seriously advise shifting tons of earth containing the roots of the bracken. If it was to benefit the poor of the district in the interest of a wealthy employer, that alters the question; but if business is meant, I should advise the gathering of the ripe spores in the autumn, sowing them in shallow pans, and placing these in a cold-frame. With about two dozen seed-pans you might raise 10,000 plants, and in the following summer they would be fit to plant out anywhere on prepared soil. About one cwt. of soil used in the above manner, would have a better result than 100 tons removed on your correspondent's plan. And if it is destruction you aim at, have it mowed down at once, and as soon as it sprouts again, and it will "bleed to death." *R. M., Newbury.*

KEW GARDENS.—I fully agree with all your correspondent "A. D." says concerning Kew Gardens, but I ask why it is that no facilities are given to see them? I cannot walk over half of them, nor can one person in ten, without being so fatigued as to lessen all enjoyment. In Paris, in the Jardin d'Acclimatation there is a miniature railway, which runs through the shrubs and trees of the Bois de Boulogne, so as not to be unightly, and at a small charge visitors are carried. Now if it is found necessary in so small a garden, surely it is much more needed in such an extensive and beautiful place as Kew. Few persons are able to walk over the 240 acres of Kew, especially when you add to this the distance from the steamboat or railway station; verily, we have much to learn from the French in such matters. The last time I visited Kew I went to see the magnificent Rhododendron valley, and the Azaleas and Magnolias, and I was so fatigued I could scarcely get back to the railway station. Now, this was only a small part of these magnificent gardens. Add to this the late hour they are opened to the public, and the whole appears to me so farcical as not to be credible. These gardens (thanks to the successive Directors) are the finest in the world; unfortunately, they are comparatively unknown, yet look at the great expense of keeping them up. Surely the public who pays could be more liberally admitted without sacrificing science. *George Davidson.* [There is practically now no difficulty about early entry to professional gardeners. Ed.]

EARLY-FLOWERING STRAWBERRIES.—Entering Mr. Carmichael's garden in Edinburgh on May 25, I was surprised to find his two Strawberries, the Queen of Denmark and Princess of Wales, in blossom; the only other in flower in the same garden being Garibaldi. I have not noted any other variety in the open air in bloom in this district, nor at Oxenford on Saturday, May 22, the Strawberries, as well as other kinds of fruit, being abnormally late. A feature of these two new Strawberries is the moderate size of the leaves, and the shortness of the leaf stalks. These qualities are valuable in open air crops, but specially so for forcing. A sturdy habit saves time, as well as economises space; hence largely the popularity of Keen's Seedling, Garibaldi, and Latest-of-All. I have already mentioned the capital row of Garibaldi seen at Oxenford the other day. The single line of plants on a shelf was an almost continuous "cord" of berries, with just enough foliage to form a background for them. Close by, and growing under similar conditions, was a batch of Royal Sovereign, carrying possibly more leaves than fruits, and their long foot stalks thrusting the foliage up against the glass. The lesson is obvious. *T. F.*

FIG. 138.—GROUP OF CANNAS.

(Established by Messrs. Cannon & Sons, Swanley, at the Temple Show. See Report of the Show, *Gard. Chron.*, May 29, 1897.)

good with *Cypripedium guttatum*? This is a Siberian species, which should be easy enough. But I lose it everywhere. *Arthur K. Patten.*

APRICOTS UNDER GLASS AT ARNISTON, PORTLAND.—Permit me to confirm all that Mr. Temple, of Caron House Gardens, said in a recent *Gardeners' Chronicle* as to the excellent Apricots, Peaches, Nectarines, and other fruits obtained last year at Arniston by Mr. McTaggart. I had the pleasure of visiting Arniston about the same time, and it seemed impossible to get more or better fruit from a somewhat limited area than were grown in that fine old kitchen garden. Grape Vines, and all other kind of fruit, were likewise well done there; while all uncropped land in the kitchen garden is ridged up every winter, and made fit to carry the finest of vegetable crops. The dell, arboretum, the

and everywhere, have as many bulbs as they will hold, and, from the Snowdrops to the late Tulips, there is no interval. The Narcissus poeticus ornatus and some varieties of Daffodils increase so rapidly that we are compelled to dig them up and divide them, but all the others are left severely alone. A bed of Dutch Hyacinths planted three years ago has had as fine flowers as the new ones planted this year, with the advantage of being about three weeks earlier. Our bedding out is done without interfering with the dying foliage of the bulbs, which is cleared off as soon as it becomes loose, or if the ends become shabby, they are cut partly off. There is an intermediate, rather untidy season for two or three weeks, which is partly hidden by succession varieties of bulbs on the same beds, but even the dying leaves are better than bare soil, and we are more than content with the result. In our experience, the more bulbs are left

VEGETABLES.

LATE BROCCOLI.

THE usefulness of late varieties of Broccoli, especially in a season like the present, when Cauliflowers, unless grown under glass, will be two or three weeks later than usual in producing heads, will be generally admitted by those who have to supply the kitchen with home-grown vegetables. After testing at different times most of the Broccoli in cultivation, I have come to the conclusion that the variety named Methven's June is so far the latest obtainable, as the supply from it will extend to probably a fortnight from the present time (May 28). Veitch's Model, a remarkably dwarf and hardy Broccoli, grown on the same quarter as Methven's, is just finished, the last head being cut at this date. No doubt much might be done by selection where time and circumstances permit of the seeding of the very latest heads. In my quarter of Methven's June, I find this year a stray plant, differing in appearance and habit from the type, and with the tiny head but just forming. I intend to seed this, and should the stock resulting come true, it will, I hope, prove to be at least a fortnight later than Methven's June. *H.* [Kindly say what dates are the most suitable for your district for sowing these and other late varieties. Ed.]

SCOTLAND.

MESSRS. DOBBIES' NURSERIES.

AFTER a journey by rail and sea to Rothesay, I soon found myself inspecting 50 acres of well-stocked nursery ground. Among many other notable features was a fine new border of all the choicer herbaceous plants, flanked at the back with climbing Roses. Here and there, so as not to over-shadow the herbaceous plants, a few of the Roses will also be thrown over the main walk that is carried along the lower side of the ground. Here, too, were over 2 acres of ground, deeply dug or trenched, manured, and roughed-up for growing the fine Dahlias; here, also, was a enormous number of beds of Violas, Pansies, Pentstemons, Pyrethrums, Phloxes, Paeonies, and hosts of other herbaceous plants looking full of promise. Nearly the whole of the ground lies on an easy slope, admirably adapted for the cultivation and effective display of such plants, as well as for the perfect culture of the thousands of Dahlias, Asters, Stocks, Marigolds, Zinnias, and Sweet Peas.

In the home nursery we observed tens of thousands of Dahlias and other plants being propagated and grown-on. The seed-shops, sheds, offices, packing places, stores of sorted written labels ready for name, date use, all told of the enormous business done in plants, cuttings, and seedlings. One of the fruit-houses entered was the central house for Dahlias, which had already yielded several crops of cuttings. This was 60 feet long and 18 feet wide, and affords many thousand cuttings at each beholding. The cuttings are rooted in houses such as that figured in *Gardeners' Chronicle*, May 11, 1895, p. 585. The plants that have supplied so many cuttings were so full of health as to suggest that the oftener they are beheld the stronger they grow.

The cuttings to the number of about seven in a 3-inch pot, if I remember rightly, root with such certainty in about a fortnight, that among the thousands present, there seemed no evidence of a single failure. They are rooted in hot-beds placed all round the sides of the house. So soon as rooted they are placed in the central bed of the house without bottom-heat. When sufficiently hardened off here, they are passed on into cold-pits, where I saw some 20,000 plants as green as Leeks, hardening off.

The Alpine-house was filled with Dahlias in 10-inch pots, growing on to bloom for the Temple Show in London. It was a novel feature.

Fuchsias and Pelargoniums, especially the scented species of the latter, are largely grown. Chrysanthemums are grown by thousands, some 20,000 early

ones for open borders being bedded out in cold-frames, and a choice collection of later blooming and Japanese varieties are grown in pots. Some 2 acres of cold-frames near to the chief office and packing-sheds contain enormous quantities of Pansies, Violas, Asters, and vegetable plants, such as Celery, Parsley, Leeks, and Onions. The practice of selling cuttings, and raising for sale improved vegetables of the finer strain in tens of thousands, only seems a thing of yesterday; but already there seems no possible limit to the area and importance of this new and unique trade. Few large plants were seen, but short, strong, stubby ones, that may be sent by parcel-post anywhere. Genial as is the climate at Rothesay, the firm grows many of their finest seeds at Orpington in Kent, where some thirty hands are employed, whilst at Rothesay there are sixty. *D. T. F.*

ALPINE GARDEN.

GENTIANA ACAULIS.

THIS is one of the richest blue-coloured flowers of all the plants which bloom in the rockery or in our borders in the spring, and it is one that everybody admires, and yet it is not grown to the extent which it deserves. The plant is apt to die off suddenly sometimes after attaining to a fair size, owing, perhaps, in some instances to the poverty of the soil, in others to extreme dryness, and occasionally to the action of frost, which lifts the plants when young out of the ground. Mr. Burroughes has a beautiful row of it at Ketton Cottage, alongside of a path about 40 yards in length. This was recently full of flowers, and I counted eighteen on a piece 9 inches square. The situation is exposed to the sun during the whole of the day, and the soil well drained. When the border was made, several years since, plenty of burnt-earth and manure were incorporated with the staple. I have seen the plant growing equally well in a damp and somewhat shady position, but never before saw the flowers so thickly placed. *W. H. Diers, Belvoir Castle Gardens, Grantham.*

LAW NOTES.

A TREE-FELLING CASE.

Ashley v. Ashley.—This is one of the most flagrant cases of tree-spoilation that ever came under my notice; as Mr. Justice Kekewich, before whom it was tried in No. 4 Chancery Court said, it was a clear case of "devastation." It occurred in the following manner:—Mrs. Ashley, who was the life-renter in the estate, bound herself over under a marriage settlement to hand the thing over to her husband if he survived her, and to any issue they might have, in fee or absolutely. Moreover, she bound herself not to touch any ornamental trees, but to hand them over to a male child she had, after her own and her husband's decease. The trustees of the marriage settlement, in the interests of the young heir, when they found that the lady life-renter was marking ad "ringing" the best trees in the paddock round about Beaver Grove, which is a residential portion in the lower reaches of the estate, on the Denbighshire banks of the Conway, and is one of the most charming sites about Bettws-y-Coed, applied to the Court of Chancery for injunction, and obtained it, subject to proof.

The case came on for hearing before Mr. Justice Kekewich, in Chancery Court No. 4, and was continued for three days till disposed of. The solicitors for the plaintiff were Griffiths & Allan; and for the defendant, D. Jones and Roberts, both of Llanryst. The experts employed were Messrs. J. A. Anderson, Manchester; Peter McIntyre (Earl of Ancaster's agent), Llanryst; and Charles Frewen, land agent, Victoria Street, London, for the plaintiff; and Walter B. Jones, Criccieth, N. Wales; Johnston, Bangor; and Wm. G. Jones, Llanfair, for the defender. Photographs were put in evidence showing about thirty of the principal trees, some of them showing the

"ringing" at the base, others showing the trees untouched; the bulk of them were over 100 years old, and showing remarkable vigour, good enough for quite another 100 years to come. The principal trees were Beech, Oak, Ash, and Sycamore, and the girth of most of them varied from 7 to 9 feet 6 inches at 3 feet from the ground; they were a remarkably healthy lot of trees, not stag-headed. The paddock is opposite the fine road on the Carnarvonshire side of the Conway, and the grove is simply beautiful, sloping up to an amphitheatre-like background. There is a house in the centre, not large, more like a highland shooting-box, but admirably adapted for a reclus, or for a lady or gentleman spending the afternoon of life. The tree scenery is splendid, and it was the grossest piece of vandalism to mark the sixty odd trees, of great beauty, for cutting down. The place has not been laid out or kept on landscape lines, and hence the disposition to slaughter these aged trees—all beautiful in canopy, but not too close together; good enough, indeed, for ornamental work for many years to come. The battle, if it had been fought out would have been an interesting one, as it would have turned on what was an "ornamental" tree, and the examination and cross-examination of the experts would have been keenly noted. The learned judge, who noted the photographs, and could tell not only which was Oak and which was Beech, but what was Irish Ivy and what Scotch Ivy running up the trunks, showed an expert at once that the case judicially was safe in his hands. On pressing the question how it was that the lady was cutting down the trees of such beauty and age, the counsel for the defendant, after consultation, replied that it was because she wished to plant young ones—a remark that caused some merriment. In the end his lordship pronounced against the life-renter with costs, the trees that were "ringed" to be cut down and realised, and perpetual injunction to be granted against the defender, with pains and penalties if there was any breach of his lordship's interlocutor. *J. Anderson.*

REPAIRING A TENNIS LAWN.

Crouch & Son v. Haig.—This action came on for hearing at the Guildford County Court recently before his Honour, Judge Lushington. The plaintiffs are florists of Guildford, and the defendant is a retired General, living at Piteroff, Epsom Road, Guildford. Mr. Furneaux, of Messrs. Smallpiece & Co., was for the plaintiffs, and Mr. Gilbert White for the defendant. In answer to his Honour, Mr. White said the defence was that the work was not done according to the estimate. Mr. Furneaux stated that early in September, 1895, Mrs. Haig asked plaintiff to attend at her residence, and to give an estimate for making up the tennis-lawn and putting it in repair. The plaintiff attended and sent in an estimate. His Honour read the estimate, in which the plaintiff undertook to prepare the lawn, and to look after the same to the middle of April, and get it in good order for £7 7s. Mr. Furneaux said he should call plaintiff and four witnesses to prove that the work was properly done. On April 30, 1896, Mrs. Haig wrote stating that she took over her tennis-lawn from that date, and she regretted she ever put it in his (plaintiff's) hands, as it was full of holes, weeds, &c., the grass was dead, and though it was within a month of the tennis season, she had no tennis-lawn, and the opportunity of making one was lost. Another letter from Mrs. Haig, written after the account was sent in, was read, in which she stated that the plaintiff had not carried out his undertaking to make the tennis-court fit to play on by that season. She had no objection to pay a fair price for the labour he gave, and for the manure and seeds, but the claim for £7 7s. was beyond all reason. Mr. Crouch, in his evidence, said the land was in a very bad state, full of holes and weeds when he first saw it, and everything was done to put the ground in a proper state. He sent five men, who were engaged in work there at different times, and the lawn was as good as they could possibly get it. Cross-examined: Mrs. Haig complained several times while the work was in progress. Mr. Wells, foreman to plaintiff, said that all

was done which possibly could be done for the lawn, short of re-turfing. Other workmen were called, and stated that the lawn was left in a good state. Mrs. Haig deposed as to the arrangements made with Mr. Couch, and said that at the end of April the lawn was full of holes, and there was a quantity of Plantain in it. The defendant's daughter said that the lawn at the end of April was full of holes, and there were bare patches, and a great number of weeds. They had a few games during the season, but had to apologise freely every time they asked anyone to the house. General Haig said the lawn was quite unfurnished as a tennis-lawn. James Tuppin, gardener, said there were bare patches, and the ground was full of holes. The ground was not rolled sufficiently. About the end of May the witness took seven or eight barrowloads of earth with which to fill up the holes. This concluded the evidence. His Honour held that the plaintiffs did not get the lawn into good order, but treated it in a superficial and perfunctory manner. The reason why they did not get it into good order was that they did not put enough work into it. He found for the defendant, with costs. The defendant had paid half the amount into court, and this will go towards the costs.

Obituary.

ALFRED GEORGE.—In the churchyard of Bicton, Devonshire, on Saturday, May 15, was laid to rest a good type of the English gardener. The deceased was a Kentish man by birth, and was gardener for many years to the late Mr. George Wyatt, of Lake House, Cliftonham, afterwards going to Bicton as gardener to the late Lady Rolle; this was in 1872. During the ten years that he stayed at Bicton he made many improvements in the grounds and gardens, developing and establishing the distinctive features introduced by his predecessor, Mr. Barnes. Some years ago he was appointed one of the lecturers on horticulture under the Devon County Council, and in which capacity he did excellent work, more particularly among the Apple orchards. His happy, gossying way of imparting technical instruction in the art of pruning, grafting, and budding, to the young farmers, who attended his classes, has already begun to bear good results in many places. He occasionally gave an evening lecture to the Devon and Exeter Gardeners' Association, and his death is much deplored by its members. A. H.

MARKETS.

COVENT GARDEN, JUNE 3.

[We cannot accept any responsibility for the unjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general average for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

POTATO.

Ware now having fair supplies of New Potatoes, which rule as follows:—Jersey Flukes and Kidneys, £11 to 12½; St. Malo and Cherbourg, £19 to £10 10s.; Dunbar Maincrops, 95s. to 100s.; others, 20s. to 70s. John Bath, Wellington Street, Covent Garden.

SEEDS.

LONDON, June 2.—Messrs. John Saaw & Sons, Seed Merchants, of Great Malze Pond, Borough, London, S.E., state that to-day's market, as might have been expected, was one of buyers and of interest. Quotations for Clover and grass-seeds are consequently unchanged. Tares, owing to the recent welcome rains, still find buyers. Rye is inquired for. Fall prices are asked for Rape-seed. Some choice Californian white sowing Mustard-seed, just landed, is offering at attractive rates. For bird-seeds the demand is heavy. Linseed is declining in value. Blue Fens and Haricot Beans, move off freely at full rates. Lima Butter-beans are firm, supplies on the spot being exceedingly scarce.

FRUIT AND VEGETABLES.

GLASGOW, June 2. The following are the averages of the prices current here during the past week:—Apples, 6½ per pound; Tomatoes, Guernsey, 8d. 3a; do. Scotch, 7s. 6d. doz; Grapes, home, 2s. by 3s. doz. Vegetables: Turnips, French, white, 1s. per bunch; do. white, 2s. 6d. to 3s. per bunch; Swedes, 2s. to 2s. 6d. per wt; Turnips, French, new, 1s. to 1s. 3d. per bunch; Carrots, French, new, 1s. to 1s. 2d. per bunch; do. Dutch, 1s. 9d. to 2s. 6d. per dozen bunches; Cabbages, 8d. to 1s. 2d. per doz; do. Dublin, 7d. to 8d. doz; Cauliflowers, Edinburgh, 1s. 6d. per bunch; do. Dublin, 2s. 6d. to 3s. per bunch; Parsnips, 1s. 6d. to 1s. to 1s. 6d. per dozen bunches; Mint, 6d. per bunch; Onions, Globe, 10s. per cent; Parsley, 1s. to 5s. per stone; Potatoes, best, 6d. to 1s., do. Paris, 7d. per lb.; Carrots, 6s. 10s. per cwt; Broccoli, 2s. 6d. to 3s. per dozen; Peas, French, 1s. 6d. per basket; Asparagus, French, 1s. 2d. per bunch; do. English, 2s. to 2s. 6d. 4b; Cucumbers, 1s. to 1s. 6s. per dozen; Lettuce, round, 1s. to 1s. 2d. per doz; do. French, 1s. 3d. to 1s. 6d. per dozen; do. Cos, 8s. 6d. to 1s. dozen; Radishes, 7d. to 8d. per dozen bunches; do. French, 6d. to 9d. per bunch; do. Scotch, 1s. 2d. per bundle; Beans, French, 6d. to 9d. per peck; Mushrooms, 1s. to 1s. 3d. per lb.; Beet-root, 7d. to 8d. per dozen; Grass, 3d. per basket; Endive, 1s. 6d. to 2s. per dozen; Spinnach, 2s. to 3s. per stone.

LYVERPOOL, June 2.—Average of the prices current at the undermentioned markets:—St. John's Potatoes, 10d. to 1s. per peck; 3s. new, 13d. to 2s. 6d.; Peas, 4d. doz.; Asparagus, 2s. to 3s. per ton; Cucumbers, 3d. to 6d. each; Apprios, 1s.

dozen; Gooseberries, 6s. lb.; Grapes, English, 1s. 6d. to 2s. do; Pines, English, 4s. to 6s. each; Cherries, 6d. to 8d. per lb.; Strawberries, 6d. to 2s. 6d. doz; Mushrooms, 1s. per lb. Bird-nest.—Potatoes, 10d. per peck; do. new, 13d. to 1s. 3d. per lb.; Peas, 4d. to 6d. doz.; Asparagus, 2s. to 3s. 6d. per 100; Cucumbers, 2d. to 5d. each; Apprios, 1s. per dozen; Gooseberries, 4d. per lb.; Grapes, English, 2s. 6d. to 3s. 6d. doz.; Cherries, 6d. to 8d. doz; Strawberries, 6d. to 1s. doz; Mushrooms, 1s. to 1s. 4d. doz. North Hay.—Potatoes, per cwt, Jersey, new, 11s. to 11s. 6d.; Imperators, 1s. 10d. to 2s. 2d.; Champs, 1s. 10d. to 2s. 2d.; Main Crop, 2s. 6d. to 2s. 10d.; Clantonis, 2s. to 2s. 3d.; Bruce, 2s. 4d. to 2s. 8d. per cwt.; Turnips, Swedes, 1s. 6d. to 1s. 8d. per cwt.; Carrots, 6s. to 7s. doz.; Onions, foreign, 6s. to 7s. doz.; Lettuces, 6d. to 1s. per dozen; Cucumbers, 2s. to 3s. doz.; Cauliflowers, 1s. 3d. to 2s. doz.; Cabbages, 8d. to 1s. 4d. doz.

CORN.

AVERAGE PRICES of British Corn (per imperial qr.), for the week ending May 29, and for the corresponding period of 1896, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

Description.	1896.		Difference.
	s. d.	s. d.	
Wheat	25 4	28 3	+ 2 10
Barley	11 5	21 3	+ 9 0
Oats	21 10	17 10	+ 3 0

GARDENING APPOINTMENTS.

Mr. W. MOUNT, until recently Foreman in the Gardens, "Newbury," East Grinstead, Sussex, Head Gardener to E. BEAL, Esq., Hazelbank, Holyport, near Maidenhead, Berks.
 Mr. R. DAVEY, for the past four years Gardener at Freshman Vale House, as Gardener to Colonel Knox, Alice Holt Lodge, Farnham, Surrey.
 Mr. ROBERT ASHMORE, Gardener to Mrs. MEADE WALDO Marsh Green, Ashover, Derbyshire.
 Mr. JOHN WATSON, until lately Gardener at The Hall, Wicks-tooth, Derbyshire, as Head Gardener to Colonel J. H. BERTALL, Hesse Mount, near Hull.
 Mr. P. TAYLOR, late Foreman at Lettesfield Park, Whitechapel, Essex, as Head Gardener to F. C. FLETCHER, Esq., Letlam Green, Abberthorpe, N.B.
 Mr. A. BEST, for the past four and a half years as Wyeck Hill, St. Leonards-on-Sea, Devon, as Head Gardener to E. J. Moxon Esq., East Hill, Kidderminster, W. Warwickshire.
 Mr. H. G. SYMES, late Head Gardener to R. B. EVERED, Esq., Oatlands, Horley, as Gardener to M. D. RUCKER, Esq., Setton Lodge, Newmarket.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

 0, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S.; 6, Principal Grazing, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, S.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending May 29, is furnished from the Meteorological Office:—

"The weather continued very fine and dry until the 24th, when it became misty, with occasional rain in the north, and this condition extended rather quickly to all other parts of the Kingdom. Thunder and lightning occurred in many parts of England during the latter part of the week.

"The temperature was below the mean, the deficit ranging from 1° in most districts to 2° in Ireland, S. and England, S., and 3° in England, N.W. and N.E., and 5° in England, E. The highest of the maxima were recorded, as a rule, on the 25th, when they ranged from 73° in England, S.W., and 72° in England, S., to 64° in Scotland, N. and England, N.E., and 63° in the Channel Islands. The absolute minima were recorded on rather irregular dates, and were also very low, ranging from 29° in Scotland, E., 30° in Scotland, W., and 32° in England, N.E. and S.W., to 40° in England, E., and to 46° in the Channel Islands."

"The rainfall was more than the mean over all the western half of the Kingdom, as well as in Scotland, E. and England, N.E., and just equal to it in the Midland Counties; in Scotland, N.W. and N.E., and in England, E. and S., the fall was rather less than the normal.

"The bright sunshine exceeded the mean in Ireland and in Scotland, W., but was either below or first equal to the normal over Great Britain. The percentage of the possible duration ranged from 51 in England, N.W., and 47 in Ireland, S., to 21 in Scotland, N., and to 27 in Scotland, E."

CULTURAL MEMORANDA.

VARIEGATED POLEMONIUM HUMBLE.

It is a great pity that so pretty a little perennial is not more often met with. It is a most effective bedding plant, either as an edging or as groundwork to such subjects as Fuchsias, Camas, or the small-flowered Begonias. One of the most charming examples of summer bedding I have ever seen was a medium-sized bed covered with this variegated Polemonium, and dotted about with Begonia weltoniensis. A variety of combinations will readily suggest themselves. It is very striking when used as a groundwork for a bed planted with red and white Fuchsias, or a mixture of scarlet and yellow Camas. In a damp shady spot where flowering plants get too leggy, this Polemonium, used with Greivillea robusta, provides a simple and attractive change.

SIBTHORPIA EUROPEA AND VARI.

For growing in pans or small baskets, few plants are more graceful and attractive than these creepers. By some they are considered to be difficult to keep during the winter; but a little more heat and less

water than is usually given them will surmount the difficulty. At Chiswick they winter *Sibthorpia europæa* var. variegata in the propagating-house, and the treatment answers admirably. If grown in pans they should be well drained; and in the case of baskets, the use of too thick a lining of moss should be guarded against, as the *Sibthorpias* dislike a damp bottom. The soil most suited for their requirements is one through which water percolates freely—leaf-mould and loam in equal quantities, with a liberal sprinkling of sharp sand and broken charcoal, will answer.

Although the white and yellow forms (*S. europæa* var. variegata and *S. e. var. aurea*) are chiefly grown, the type (*S. europæa*) with green leaves is very graceful, and makes a good companion to the others. The flat appearance of the baskets or pans may be well relieved by placing a few pieces of soft brick or stones on the soil, thus giving a pleasing appearance. *Sibthorpias* may also be profitably grown in small pots for an edging to the conservatory stage. *A. C. Earlett.*

PACKING SEEDS AND TUBERS FOR LONG JOURNEYS.

The *Chion*, as quoted in the *Revue Scientifique*, mentions a method of forwarding and packing seeds and tubers which seems ingenious and practical, especially when the journey will be long, and warmth and dryness are likely to have injurious effects. The method employed by a Lot florist consists in moistening a little plaster, and imbedding the seeds, tubers, or rhizomes which are to be transported in this. This plan has succeeded well for packing rhizomes sent from Japan, roots of aquatic plants, the lengthened transit of which is always a difficulty. Enveloped in plaster, the plants, or pieces of plants, are in no danger; they cannot become parched, and are kept in a satisfactory condition of partial moisture. It would seem that this plan would also succeed under other conditions. In Australia it is employed for the transport of fresh butter. The butter is made up into blocks with parallel and rectangular surfaces, to which are pressed glass slabs of the same sizes as the sides and ends of the blocks of butter. The edges are covered with gannet paper for greater security, and the whole is then covered with plaster to a thickness of 6 millimetres. Plaster being a poor conductor of heat, security and the butter against the variations of the temperature, and enables it to be kept longer than is possible under other methods of packing.

ANTS: *E. J. S.* The other means having failed to rid the houses of the ants, you should try the Balkinmain Ant Destroyer. See advertisement columns of *Gardeners' Chronicle*, May 22.

BOOKS: *G. Robertson.* One of the best of which we know, which embraces the period 1843-92, is Mr. William Paul's *Contributions to Horticultural Literature*, published by the author at Waltham Cross, Herts.

BOUVARDIAS: *J. M.* The young Bouvardias have got into a bad condition of growth. Being potted too deep may have something to do with it, but probably the poorness of the soil or the want of sufficient pot-room would be a more likely reason. The young plants should be potted into small pots, and potted back and kept stopped until the end of the summer if wanted for winter-blooming. The plants may either be potted on as they require it, or planted out into a border in the open ground, where they should be carefully tended, lifted, and potted, and placed for a time in a cold, shady frame at the end of the summer.

CAPE TOWN NERVEYAN: *C. Schmutz.* We are unable to give you the names of any others in Cape Town.

CARNATIONS DECAYING: *A. Davis.* The probable cause is an attack of rot-worms in the roots. Burn the plants root and top forthwith, and plant the new bed of Carnations on clean soil, not incorporating any pasture manure, such as may have been used in the other bed. Trench the old bed after dressing it with rape dust, or meal or gash.

FISH SHRIVELLING: *J. G. S.* It is common for some fruits to shrivel and fall in the manner you have done; but such cases are most frequent upon trees that have been forced. The only explanation we can offer is that from some cause or other the trees have received a check. Get your shoots thoroughly ripened during the present autumn, as being the best means of preventing a recurrence of the circumstance next spring.

GREEN CENTRES TO MARÉCHAL NIEL ROSES: *J. S. W.* This is in reality an excess of growth, due to some climatal change, or to low temperature combined with an excessive degree of moisture at the root. The Tea Rose is in all its varieties delights in a dry, warm, well-drained soil.

INSECTS: *G. J.* They are millipedes, and feed chiefly upon decaying matter. The Potato trouble must be attributed to other causes.—*W. E. Neunotid worms, Gordius varius.*

MARIE LOUISE VIOLET PARTLY FAILING TO BEING PERFECT FLOWERS: *Alexander Videl.* Probably the blooms are cleistogamous. Kindly send some for examination.

NAMES OF FRUITS: *Flowers, Strawberry, Myatt's Eliza—J. Botwell, Sudbury Hill. Apple, Dumelow's Seedling.*

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to good to consult the following number:—W. S. L. P. 1, Papaver rufifragrum × orientale; 2, Crepis rubra; 3, Hebebra micrantha; 4, Lathyrus Sibthorpi var.; 5, Smilacina stellata; 6, Sedum praealtum—Zabel. 1, Alob pictatis; 2, Ardisia multiflorum; 3, Dendrobium Benouise; 4, Manettia bicolor; 5, Velezia officinalis—H. E. W. Fraxea verucosa.—R. C. Orlonolozosium hae (Heichenheim), Bot. Mag., 6265.—W. C. Pyrus tormalis.—W. T. J. 1, Aspidium maximum; 2, Helium religiosum; 3, Scilla peruviana; 4, Ornithogalum arabicum; 5, Thunia occidentalis var. Elmgrow. 1—Alph. 1, Cratogeomys pyracantha var. Lelandi; 2, Davallia canariensis; 3, a variety of the common Fern.—C. G. Bromus mollis—J. Barre. Matris is insufficient.—R. V. H. Cypridium Hookeri.—Suisse. Dendrobium crataecium, so far as we can judge by the withered flower sent.*

Peach LEAVES BLISTERED: *S. J. W., H. R., and C. G.* The blistering is caused by a fungus, *Xoosoma deformans*, and you can do nothing now beyond cutting off the worst affected and burning them, and dressing the remaining foliage with dry flowers-of-sulphur, or the same in solution with water. The trees will outgrow the injury to a certain extent, but it will be prudent to afford manure-water later. We believe it may be checked by spraying with Bordeaux Mixture, or sulphate of potassium, early in the year, when the leaves first expand.

PEACHES ANOMALOUS: The paleness of the leaf is probably due to the condition of the soil, and the fruit is affected with a mildew. For the latter there is no known cure, but the fungus can be prevented from spreading by the use of sulphur.

RATING OF TRADE GREENHOUSES: *Enquiries.* They should be rated to the poor at one-fourth of the rate levied on other kinds of property.

SEEDS: *A. K.* The growers of seeds are usually much engaged in stocking, to which the wholesale seed merchants and the nurserymen in a large way of business send stocks of seeds to be grown, and the seeds after the ripening of the plants whilst in growth, harvested and cleaned. We should think that you would do best by getting into communication with the wholesale merchants in the first instance.

VINE LEAVES: *E. B.* The warty appearance observed on the under-side of some of the leaves sent, betokens an excess of humidity in theinery, or what is almost the same thing—a lack of ventilation; and the browning of the foliage comes from redding, due also to lack of ventilation. This kind of scalding is not uncommon about the middle of varieties of great width.

COMMUNICATIONS RECEIVED.—J. C.—Dr. Franciscus—S. B. Bura.—O. T.—C. de R.—H. C.—L. P.—J. B.—W. W.—D. M.—C. J. W.—A. L. Manilla.—W. E. S.—G. W.—R. N. Hooper.—G. Jones.—E. H. B.—R. D.—T. Harris.—H. M.—D. V. F.—J. Baxter.—J. W.—A. M. O.—A. D.—B. T. M.—C. de Bossière.—U. D.—J. MacD.

THE

Gardeners' Chronicle.

SATURDAY, JUNE 12, 1897.

PLANTS OF THE VICTORIAN ERA. ROSES.

As everybody seems now to be engaged in recounting the glories and progress of the past sixty years, I do not think it will be out of place if we dwell for a little while on what has been done in the Rose-world during that time. We may not have to tell of such great things as have been accomplished in other ways, though we cannot but rejoice in the altered state of most things around us. We think with pleasure of the improved condition of our labouring poor, and of the greater comforts which they now enjoy; we think, too, how many horrible practices have been done away with; how the prize-fights, of which Dr. Conan Doyle has given us such a vivid description in *Rodney Stone*, have ceased; how poor little boys are no longer sent up chimneys, nor girls of tender age sent down to work in mines, and we see in most places proofs of the increased prosperity of our country—but, sitting in my country vicarage, and looking round, and seeing the changes for the worse which have come upon all having to do with the land, landlords, parsons, and farmers, I feel that there must be some foil to the very bright picture people are continually drawing.

But passing from this digression, I think few Rose-growers have realised what they have gained during that period. Can we bring to our minds the time when hybrid perpetuals had not yet risen to the dignity of a class, when Tea Roses were almost unknown, and we were dependent on what are called summer Roses for the adornment of our gardens; when the dwarf Polyantha Roses had not been introduced, when in effect we had no Marie Baumann or Charles Lefebvre, no Duke of Edinburgh or Mrs. John Laing, no Catherine Mornet or Comtesse de Nadaillac, no Maréchal Niel or William Allen Richardson, and no "Her Majesty." Such a state of things is hardly conceivable now, and yet such was the case at the beginning of Her Majesty's reign.

During the period of the last sixty years, it is very difficult to say how many Roses have been sent out into the world, but if we take the average as forty each year, there cannot have been fewer than between 2000 and 3000 Roses sent forth from raisers abroad and at home; and the question will naturally occur, what has become of them? Of course, the greater portion of them have passed into oblivion; hundreds were sent out which ought never to have been put in our catalogues, while others which were good in their time, have been superseded by better flowers in the same colours—and it is

hardly fair to judge the Rose-growers of fifty years ago by the standard of to-day, for no doubt many of them did think when they sent out their flowers that they had reached the acme of perfection. I gather this not only from my knowledge of Roses, but also of other flowers. When a man names a flower which he has raised after his wife or some particular friend, it is evident that he means to put an especial honour upon it, and thinks it well worthy of it; thus, in the *Gladiolus*, when I recollect that dear old Souchet called one after Madame Souchet, I have no doubt he thought he had raised a flower of great excellence, yet if we could put it alongside of some of his own raising of recent years, he would be surprised to think he could ever have so called it.

Then, again, the price which is put upon plants is another pretty sure index of the raiser's estimation of their value. I can well remember when 5 guineas were cheerfully paid for Garth's Joan of Arc Polargonnium, and the public expressed their high opinion of it; yet ten years afterwards there was probably no collection in which it was found, and people wondered how they could have been so foolish as to give such a price for so starchy and loose a flower. I write all this because I do not think it is quite fair to denounce the raisers and senders out of those older varieties as if they designedly took in the public.

HYBRID PERPETUALS.

The three classes of Roses whose improvement have been so remarkable during the past sixty years are hybrid Perpetuals, Tea-scented, and Noisettes. The origin of the former is a matter of considerable doubt; but I believe that the Hybrid China, crossed with Damask, Hybrid Bourbon, and other Roses, have produced some of the magnificent flowers which we now possess. Two of the most celebrated raisers in the older days were Laftay and Vibert; but I do not think any of their productions have survived to the present day, except in a few garden Roses such as *Gloire des Rosomanes* and *Aimée Vibert*. The origin of the Teas and Noisettes is somewhat better known; they are the product of the China Rose crossed with the yellow China or Tea Rose; and I believe that all the fine varieties that we possess are traceable to this combination. The Noisette Rose was raised in America by M. Philippe Noisette: it was produced from Old Musk fertilised with the common China Rose, and from the very first has been a great favourite with the French Rose growers; but its earlier admirers could never have anticipated the glorious results which have followed during recent years.

The onward progress of hybrid perpetuals has been very remarkable, although at the same time, notwithstanding all the efforts of acute and persevering hybridisers, there are some that seem to hold their own amid the more recent productions. Take, for example, General Jacquemint, whose introduction I well remember in 1853; there are times when it still maintains its position against all competitors. But probably few persons have realised the fact that there are no Roses in this class which go back to the period of Her Majesty's accession, and that by far the greater number of the exhibition Roses date back to the '60's and '70's, so that when we take the lists of Roses recommended by the National Rose Society, or by such authors as Mr. Foster Melliar, or the Dean of Rochester, or those of any of our great nurserymen, you may be sure that all of them are of the Victorian

Era. There are some of the Roses in the earlier portion of that period which were very beautiful, but for one reason or another, they have had to give place to others; thus, that exquisitely-formed *Rose Comtesse Cécile de Chabrillant*, which after its introduction in 1858 used to be so exquisitely shown by the late Mr. Hedge of Colchester, was to be seen in every exhibitor's box, has been deemed too small for the present generation, which in true barbarian fashion worships size; while such brilliant flowers as *Eugène Appert*, which I recollect the late Mr. Standish showing in good style, and which for brilliance of colour and beauty of foliage has never been surpassed, has been forced to succumb, owing to its imperfect form. And so, again, *Géant des Batailles*, which the late Mr. Rivers looked upon with such favour, and which became very popular after its introduction by him towards the end of the forties, is now rarely to be met with, one reason being its great tendency to mildew. But after all these eliminations, what a galaxy of glorious flowers remains, all the productions of this reign; and the scarcity of the additions during the last few years, shows, I think, that there is not much more to be done in the improvement of this class—and this is certainly true, at any rate, with regard to foreign raisers, who have added nothing valuable to it in the past few years. A trenchant remark of the *doyen* of Rose exhibitors—Mr. B. R. Cant—confirms this statement. Knowing that he had kept a memorandum-book of all the foreign Roses that he had bought in each year, I asked him to let me have a look at it, which he has most obligingly done. It is now before me, and it is very curious to see how many there are which he propagated which never made any mark; while others which were much sought after once have dropped out of cultivation altogether. He received the Roses direct from the raisers, and hence it is worthy of note, that whatever may be said to the contrary, Guillot, the raiser of La France, put her down amongst the Hybrid Perpetuals. Mr. Cant says, "I became so disgusted with the lot of worthless Roses that were sent out, that I gave up buying in any quantities as years went on." How prolific the '60's were in good Roses may be seen by the following, which are noted in Mr. Cant's list, and which still maintain their position as exhibition Roses:—Alfred Colomb, Annie Wood, Baroness Rothschild, Camille Bernardin, Charles Lefebvre, Comte Raimbaud, Comtesse d'Oxford, Devienne Lamy, Dr. Andry, Duchesse de Morny, Du do Wellington, Dupuy Jamain, Eugénie Verdier, Fisher Holmes, Horace Vernet, Louis Van Houtte, Madame Victor Verdier, Marguerite de St. Amand, Marie Baumann, Marie Rady, Marquise de Castellane, Maurice Bernardin, Mons. Noman, Pierre Notting, Prince Camille de Rohan, and Xavier Olibo.

The '70's produced much fewer, the most noticeable among them being A. K. Williams and Madame Gabrielle Luizet; while during this time we received several Roses with high-sounding descriptions which turned out only to be reproductions of Roses already under cultivation, and which had to be classed in our catalogue as Roses synonymous with much older varieties.

Hitherto, I have dealt only with the foreign Roses. There were during this period a few English-raised ones of note, although it was somewhat difficult to determine their exact position, as it was a custom with some people to purchase the stock of some French Rose, to

give it an English name, and bring it out as if it were an English Rose; however, a new era dawned, and the late Mr. Henry Bennet, of Stapleford, near Salisbury, commenced his work of hybridising, and began to send out what he called "pedigree Roses." This term, as I contended at the time, is an incorrect one, as it is generally used to signify those things of which the preceding generations may be traced. Thus, for instance, we speak of the pedigree of a race-horse or of a short-horn, because, if we enquired of the origin of either we should be shown books in which their forefathers could be traced back for several generations; whereas, as in the case of Mr. Bennet's Roses, nothing more was implied than that the father and mother of the variety were known. I remember well going to see him at Stapleford, where I saw his earlier productions and experiments. I felt convinced that he was upon a right track, but thought but poorly of the first half-dozen that he sent out; he was too hasty in so doing, naturally enough, perhaps—but not one of them, I believe, remains in culture at the present time. His practice seems to have been mainly to cross hybrid perpetuals and Teas; and certainly the results were very remarkable. He afterwards removed to Shepperton, and unquestionably left a name behind him as a most successful raiser of new Roses. In Mrs. John Laing we have, I think, the best Rose of its colour in cultivation; this is shown by its heading the list in the selection of Roses, and by its being included in almost every stand of superior merit. Again, "Her Majesty" (fig. 143) is, no doubt, a grand Rose of its colour, though, unfortunately, dreadfully subject to mildew. In Lady Mary Fitzwilliam and Viscountess of Folkestone, we have flowers which very plainly show the admixture of Tea-blood in them; the former a very poor grower, and the latter a Rose which is a great favourite with some, though I confess I do not care a great deal for it.

Unfortunately for the Rose-world Mr. Bennet died before he could carry out all his plans; at his death his stock was dispersed, and many of his plants came into the hands of other growers, by whom they were sent into commerce—we may instance among them Captain Haywood and Clara Watson, and perhaps there may be others yet to come. Before Mr. Bennet had passed away another firm had entered upon the same course, namely, Messrs. Alex. Dickson & Sons, of Newtownards, co. Down, Ireland; they have each year sent out varieties of their own raising, and have been successful in obtaining several Gold Medals of the National Rose Society for new seedling Roses. Commencing with Earl of Dufferin, in 1887, they have sent out twenty-seven Roses, some of them of undoubted merit, while others, I am afraid, will have but a temporary popularity; they are mostly light-coloured Roses, and I think probably amongst them the best are Mrs. Sharman Crawford, Helen Keller, and Mrs. W. J. Grant. The last-named was purchased by an American firm, and was brought out as Belle Siebrecht; it is called a hybrid Tea, but I cannot say that I see much of that cross in it.

TEA ROSES.

In Tea Roses we have, on the other hand, received nearly all our most valued varieties from France. It is a curious fact that Devonians, which was for a long time the only English raised Tea of any value, dates back from a period almost coincident with the commencement of Her Majesty's reign, for it came out in 1838. Indeed, until Miss Ethel Brownlow was

sent out by Messrs. Alex. Dickson & Sons, it stood alone, and very few additions have been made on this side of the Channel. All the grand Teas from Niphetos sent out in 1843, down to Maman Cochet in 1893, have come to us from abroad; we have received some from America, but they have been mainly sports, and it seems now almost as if, in this class as well as in H. P.'s, France has done all she can for us.

GARDEN ROSES.

In garden Roses also there have been charming additions in the class of Noisettes;

summer Roses, hybrid Chinas, hybrid Bourbons, Gallicas, &c., and lamentations are continually poured out about their absence from our gardens, and laudations of the grand bushes of former days are continually made; but I cannot but think that if some of our more brilliant-coloured H. P.'s were treated somewhat in the way these Roses used to be, we should have as grand a display as the most brilliant colour among them ever gave. Thus, if for instance a plant of General Jacqueminot budded on a standard were allowed to have free course, we should have a grand bloom in June

FIG. 139.—ATTLEYA "QUEEN-EMPRESS." (SEE P. 384.)
(4 of 4 of the sepals and petals erect, sepals tip white with a crimson centre, side lobes yellow.)

what garden is complete without William Allen Richardson or L'Idéal? I say nothing of Marchal Niel, as it is more suited for the greenhouse.

Other classes of Roses have, during the latter portion of this period, come into much notice: one is the class of hybrid Teas, and to which some good additions have latterly been made, although I quite think, with the late Mr. Rivers, that the fewer the divisions, and the more simple the classification, the better; still they serve the purpose of keeping the more decided Tea and Noisette Roses in a class by themselves. It is somewhat remarkable that no attempt has been made in what are called

or July with a prospect of autumnal flowers also. In that case the blooms would have to be left on in clusters, for no one used even to think of disbudding summer-flowering Roses, and, doubtless, the desire to have large and well-formed flowers has prevented this plan from being adopted.

The bold attempt so successfully carried out by Lord Penzance of hybridising the Sweet Briar has given another charming class to our Rose gardens. He has in the pages of the *Reservoir's Year Book* showed with what care he has carried out his plan; while the beautiful varieties which, with the exception of the first two raised (Lord and Lady

Pouzance), bear the names of Sir Walter Scott's heroines, have been distributed by Messrs. Keynes, Williams & Co., and are now to be found everywhere—their tints are very varied, and they are not quite single, and are, therefore, not quite so evanescent. For covering a fence they are admirably suited, while the delicious fragrance of the type is found in the foliage of all of them.

POLYANTHA ROSES.

There is yet another class which has received some remarkable additions during the past few years, that ordinarily called Polyantha; the Japanese Rose multiflora or simplex has been crossed with some of our Teas, and has produced a delightful class of dwarf double Polyanthas,

Madame Georges Bruant, may be the *avant courier* of many others.

I have not noticed, as I might have done, the many good Roses which we owe to sports, such as Prince Arthur, a dark and highly-coloured sport of General Jacqueminot, brought out by Mr. B. R. Cant; Sir Rowland Hill, dark claret sport from Charles Lefebvre, brought out by Messrs. Mack & Son, which obtained a Gold Medal of the National Rose Society; Souvenir de S. A. Prince, a sport from Souvenir d'un Ami, sent out by the late George Prince, of Oxford—but, in truth, I have trespassed too much on your space already, and must close this imperfect but honest attempt to give some idea of how much English gardens owe to the Roses of the Victorian Era. *Wild Rose.*

and to varieties was very much what had been known from the date of the European peace onwards; and, indeed, the advance was slow until we had passed into the fifties, when there seemed to be seen the commencement of a new era. During the long period which had preceded 1851, the year of the famous first great International Exhibition, the great mass of the British people had not been fruit-consumers on a large scale. Practically, beyond getting such small supplies as were furnished, the general culture of fruit of the higher order was found only in the gardens of the wealthy, and those large manufactories of fruit, as they really are, now to be seen in all directions, had not then been dreamt of; they are the product of the gradually growing requirements of a richer public, as well as of the removal of the duty on glass, an impost that pressed on horticulture in this way with exceeding harshness. When that tax was removed there came also more correct ideas as to heating glasshouses, the old brick flues being superseded by hot-water pipes and boilers, and these two things conjoined soon made possible what was before impracticable. From that time fruit culture for the people became an important industry, while now, it is a very remarkable one. Products and prices have been revolutionised, and to-day anyone with moderate means may purchase superior glass-produced fruit with comparative ease. Still further, we owe something to the skill and enterprise of that much-deprecated being, the foreigner, who in realising that a great and wealthy people such as inhabited the British Isles must present a great market for fruit, and finding our ports, thanks to Free Trade, open to him, soon sent into our markets in a wonderful way the choicest fruit products of favoured regions. How many of us have grumbled at and deprecated these imports, yet how many have forgotten the undoubted fact that whether indoors or out, few things have done more to stimulate home culture and induce splendid efforts to counteract these things than have the imports themselves. But for them we might have been as much asleep respecting fruit-production as in the earlier days of the Queen's reign. But the supplies of fruit sent into our markets, no matter from what source, have but helped to excite the public palate, and the demand for more increases from year to year. Whilst we may rightly and admirably do our very utmost to grow our own fruit to satisfy our own needs, at least we may not forget what we owe to the foreigner for his example in culture, in method, and in marketing, and how beneficial these things have been to us as a nation! We have but to go on producing the best—for it is only the best that is found profitable, and in no matter how great abundance, a market for it will be furnished, so long as the people have ample means; whilst the more fruit that is consumed—and this fact at once ennobles fruit-culture—the healthier and the happier the community will be.

FIG. 140.—ODONTOGLOSSUM CRISPUM "QUEEN VICTORIA." (SEE P. 384.)

Colour of the sepals white, suffused with pink; petals whiter; blotches chocolate-brown; lip white, fringed with yellow, and blotche l with brown.

and such flowers as Cecile Brunner, Ma Paquerette, Gloire de Polyanthas, Perle d'Or, and others, form a class which we cannot now afford to neglect, blooming, as they do, in large clusters, and of a bright and pleasing colour. To these must be added that remarkable Rose, Crimson Rambler, introduced by Mr. Charles Turner, of Slough, and probably the most successful Rose of recent years. It is suitable for pots and pillars, but not for walls, for it suffers much from thrips.

To the Japanese we also owe those Roses of the ferocious and rugosa character, which, whether in flower or fruit are valuable, and which may probably yet give us, under the hands of the hybridiser, a new class; the attempt has already been made, and the double-flowering one,

FRUITS OF THE VICTORIAN ERA.

IT is impossible to do anything like justice to this subject in the short space of an ordinary paper. If we had a horticultural historian who would undertake to chronicle the progress of gardening in all its branches during the nineteenth century, then would fruits and their progression form a very important feature of the work. In any such history, no period would stand out with greater clearness than would the second half of the century, including, as it does, especially in relation to horticulture, the most brilliant portion of the reign of Queen Victoria.

The year 1837 found fruit culture in an advanced yet hardly in a progressive state. What was known then in relation to culture

APPLES AND PEARS.

A brief sketch of the varieties of fruits in commerce in 1837 shows that we have, during the sixty years that have since then elapsed, added to them enormously. There were in those days of garden Apples about 130, and of these now about thirty are held in esteem, the rest having mostly disappeared. On the other hand, Apple varieties now are legion, and the best greatly excel in average excellence, the best of the earlier period. The following com-

prised the pick of the dessert section then, and are still well known:—Red Astrachan, Red Quarrenden, Margil, Adams, and Scarlet Pearmain; Kerry, Fearn's, King, Ribston, Blenheim, and Cackle Pippins; Downton and Yellow Ingestrie. Of cooking sorts:—Flower of Kent, Emperor Alexander, Hoary Morning, Yorkshire and Northern Greenings, Norfolk Beeting, Hambleton Deux Ans; Manx, Keswick and Carlisle Codlins, Royal Russet, Dutch Codlin, Old Hawthornlen, Lord Nelson, and Mischall, or French Crab. Of the latter, how few appear now in the best collections, or are grown for market! Of the former, several of the Pippins still occupy a high place for flavour, being in that respect almost only excelled by Cox's Orange Pippin, the dessert Apple *par excellence*; but many fine additions to the section have been made during the past twenty years, as our fruit exhibitions disclose.

As with Apples, so with Pears. Although the exceeding value of Paradise and Quince stocks, for these fruits was well understood prior to the thirties, it was a long time ere they came into common use as now, and without doubt, their wider employment has done wonders in helping to popularise hardy fruit culture at home. Pears in the thirties were limited to about fifty varieties, the best of which to-day are Williams' Bon Chrétien, Marie Louise, Chaumontelle, Jargonelle, Bourré Diel, Passe Colmar, Glou Moreceau, Duchesse d'Angoulême, Citron de Carmes, and Gansel's Bergamot, with Catillac and Uvedale's St. Germain, baking Pears. But very few of the eating varieties mentioned in this brief list rank high to-day, but the additions made during sixty years have been considerable. A select list of Pears would now comprise very superior excellence both in size and quality. Beyond the introduction of the single corlon in cultural methods, general training remains very much what it was.

PLUMS.

In the early period under notice there were about twenty-eight good class Plums in cultivation, and two or three Damsons. Of the former, Green Gage, Orleans, the Magnum Bonums, and Coe's Golden Drop existed, and they are well known still. But whilst the present Plum list is not an extensive one, it is mainly because so many of the old ones have gone out of existence, newer ones having entirely displaced them. What splendid fruits the Rivers' firm have given to the world, and the famous Victoria itself was not when the Queen came to the throne; we had the common and Janne Damsons in 1837, but a few other good ones have been added.

CHERRIES.

With respect to Cherries, May Duke, Elton, Black Eagle, and Bigarreau still remain amongst our best orchard varieties, and bid fair to be so for many years. We have, however, added to these largely from various sources, especially from the Continent; and the best of to-day, such as are grown in orchard-houses and on walls, are indeed grand fruits. We had the Morello and the Kentish, too, in the '30's, to furnish preserving fruits, and they are not excelled for that purpose to-day.

GOOSEBERRIES AND CURRANTS.

The Gooseberry in the early years was represented by from sixty to seventy varieties; and judged by those that have lived till to-day, the spiny bush was well to the front in the excellence of its fruit. Crow's Bob, Whitesmith, Rildeman, Keen's Seedling, Roaring Lion, and

Rumbullion are still well known of larger fruits; whilst of smaller or dessert varieties, Champagne, Ironmonger, Early Rough Red, and Patnaston Green Gage have hardly been excelled for flavour. No doubt the two most popular market Gooseberries are Lancashire Lad and Whinham's Industry; and Keepsake, Crown Bob, Red Warrington, and Whitesmith run them hard in popular esteem.

Currants had not in '37 attained any high position as garden fruits; but since that day we have given them better culture, and materially improved varieties. Those were in the days mentioned apparently limited to the Red and White Dutch and the Black Naples. These are still grown, but we have finer varieties now.

is without one or more of them; indeed, they have become indispensable.

With Nectarines, although there were about fourteen in cultivation at the early date, still is our list of esteemed good varieties not a long one. Elruge and Violette Hâtive were the best of that day. We have added to these a few such very superior varieties that the best are now universally grown. Her Majesty, Early Rivers, and Lord Napier alone suffice to illustrate the progress made in Nectarines.

Among the numerous acquisitions to hardy fruits raised at Sawbridgeworth by the late Thomas Rivers and his son, Mr. T. F. Rivers, few have taken a higher place than Nectarines, some of which are much earlier or later

FIG. 141.—NARCISSUS "VICTORIA": SEAMENTS WHITE, CUP PALE YELLOW.
(Specimen from Barr & Son. See p. 384.)

PEACHES AND NECTARINES.

The Peach had at least thirty-two representatives, the best of which, judging by their general culture to-day, were Royal George, Noblesse, Barrington, and Late Admirable. Some introductions from America, prolific and precious, have materially helped to make the season of the Peach far earlier than it previously was, but Late Admirable still remains one of the best late varieties. Many newer and undoubtedly superior mid-season sorts have been introduced during the period of the Queen's reign. Whilst outdoors culture remains pretty much the same, under glass Peach and Nectarine culture has marvellously extended, although the same principles of training and of culture prevail. In 1837 Peach-houses were rare in most gardens. To-day no good garden

in ripening, and have larger fruits of better appearance than any that were previously cultivated. Of these, we have only to mention Lord Napier, Newton, Advance, Albert Victor, Byron, Darwin, Improved Downton, Pine-apple, Spenser, and Victoria, the subject of our illustration this week (fig. 141). This fruit is of a very large size, greenish-yellow, crimson on the sunny-side, rich and sugary, partaking of the flavour of the Stanwick. It is one of the finest varieties, but should not be planted outside in any but the warmer parts of the country. Under glass the fruit ripens with gentle forcing. Out-of-doors the fruit is ripe at the end of September.

Of all stone fruits the Apricot has made least progress. That is very remarkable. We had in 1837 Moor Park, Heus Kirk, Breda, and

FIG. 142. GLOXINIA "HER MAJESTY," SNOW WHITE. (SEE P. 381.)
(Pat. of W. Messel, Stuttgart & Co., Baden.)

Orange; and we have nothing better now. Its character as a "miffy" or uncertain doer seems always to have marked the Apricot.

GRAPES.

In Grapes we had sixty years since their first-rate varieties as Black Hamburgh and Muscat of Alexandria, two varieties that promise to be of the best sixty years hence; also the Frontignans, West's St. Peters, Syrian, and Black Prince.

It is the two first-named almost exclusively that have high reputations, and we have not in blacks, perhaps, with the exception of Madresfield Court, excelled the Hamburgh in flavour; and certainly, of all the tribe, Muscat of Alexandria still remains the best. The more modern additions that now have good reputations are Madresfield Court, Gros Colmar, Alicante, and Lady Downes; and the best white is perhaps Mrs. Pearson or Lady Blunt. It is rather in Grape culture under glass that advance is shown, for has it not become a huge industry, and are not our Grapes unequalled in the whole world? What glass Grape culture will be sixty years hence baffles the mind of man to imagine.

PINES AND MELONS.

The culture of the Pine has materially declined in Great Britain during the past sixty years, but that is the only fruit showing a downward tendency. The Melon has advanced enormously, and is now chiefly grown in houses rather than in pits. Of the few varieties in cultivation in the thirties not one remains, but since then myriads of so-called seedlings have come and gone; and we still put a dozen of so-called new ones into commerce every year, not that the new ones are one whit better than were those which preceded them—but it is a little way we have concerning Melons that has at once its business as well as its comical side. When once we get a Melon that is ever first-rate in quality of flesh, and ever constant to that character, then shall we obtain a real acquisition.

Figs.

Of Figs, the best of the old ones, some nine in number, are still grown, Black Ischia, White Marselles, and Brunswick, but these are being largely superseded by others of greater excellence, of which we have many. A roomy Fig-house is now frequently found in gardens—not one of the ordinary type, but such an one as is to be seen in the Chiswick Gardens, where the culture of Fig-trees in pots is so admirably displayed.

RASPBERRIES AND STRAWBERRIES.

There remains the Raspberry, the *personal* of which has been entirely changed, and greatly for the better. There is no other important fruit to refer to but the Strawberry—still our earliest fruit to ripen in or outdoors. There was a score of sorts in cultivation in 1837, the best known of them to-day being Koenig's Seedling, Grove End Scarlet, and the Hantbos, although these two latter have very restricted culture. We have had introduced to commerce many fine varieties, the best of the older introductions being British Queen, Elton Pine, President, Sir J. Paxton, Sir C. Napier, and the French Viscontesse H. de Thury. These, in spite of newcomers, of which there have been legion, still hold their own; but a few of the latest introductions, notably Royal Sovereign and Latest-of-All, bid fair to be of permanent value. Messrs. Laxton, Mr. Allen of Gunton Park, Mr. Ketley, and Mr. Lovell, who have done so much to improve the Strawberry, have others also that

merit warm approval. Strawberry-culture, both under glass and outside, has, during the Queen's long reign, developed enormously; indeed, as with most other fruits, whilst we have been making improvements in quality, size, and productiveness all round, yet with patience and slowly, the development in cultivation, whether privately or in a market sense, has gone on literally by leaps and bounds, and happily it has proved to be eminently profitable as an industry also. Not the least interesting feature of it is, that employment has been in this way furnished to industries thousands of our teeming population.

THE WEEK'S WORK.

THE ORCHID HOUSES.

By W. H. WHITE, Orchard Grower, Burford, Dorset.

Cypripediums.—*C. superbum* (Veitch) is a plant frequently seen in indifferent health. It is injured by sunlight, and even subdued light without shading will cause the leaves to assume a sickly hue. *C. Schlimi*, *C. Fairieumum*, and the pretty hybrids, *C. Arthurianum*, *C. vexillarium*, *C. H. Ballantine*, *C. Niobe*, and *C. Statteriana*, are also extremely liable to injury from much direct sunlight. To keep these *Cypripediums* in good health, it is advisable, in addition to the ordinary roof-shading, to place a sheet of tissue paper over them whenever the sun shines strongly. They delight in a thorough watering at the roots every few days, and on no account should the compost be allowed to become dry.

Lycastes.—At the present time the plants have started well into growth, and will soon commence to emit new roots from the young breaks. If reporting by necessity it had better be done at once, using pots of moderate size, which must be half filled with drainage. The compost should consist of equal parts fibrous loam, peat, leaf-mould, or dried cow-manure, with a little sphagnum-moss pressed in over the surface. Until the new roots have obtained a firm hold of the soil, very careful watering is necessary, as the young growths, like those of the deciduous *Calanthes*, at this stage, are prone to rot if too much water is afforded, although when well established they will take an abundant supply. *Lycastes* may be grown at the warmest end of the cool-house, and should be kept well shaded in sunny weather. While in full growth the foliage should be sponged occasionally to clear it of red-spider.

Eulophiella Pectorisana.—Newly-imported plants of this new species which may be starting into growth should be afforded some peat and sphagnum moss in which to make root, the young breaks quickly emitting roots from the rhizomes. Owing to the rambling habit of the plant, a good deal of space is necessary for full development, and large, shallow pans are to be preferred to pots in which to grow it. It does best in a damp shady position in the East Indian-house or plant-stove. Like the allied species, *E. Elisabethae*, this species requires abundance of water whilst making its growth. I may mention that at Burford Lodge there is a strong, well-established plant, the newly-made pseudo-bulbs of which measure about 15 inches in length, and they bear two large leaves, the longest of which is more than 4 feet in length.

Dendrobium Phalænopsis, &c. — This, the most beautiful of *Dendrobiums*, flowers late in the year, therefore at a season when most Orchids are out of bloom, and its long arching spikes produce numerous flowers, which vary in colour from white to rich crimson purple. The plants have been at rest for the last six months, but growth having recommenced, they will require attention till growth is finished. For some time the young shoots are usually thin and weak, and the inexperienced cultivator will be under the impression that strong-flowering bulbs will not be produced; but such is not the case, the base of the shoots becoming hard, producing plenty of new roots, and rapid growth and strength ensue. If a plant should require re-potting into a larger pot, this should be done before the new roots push forth; or if the potting material is worn out, it should be picked from among the roots, and fresh compost afforded. Additional root-espice should not be given, unless it be absolutely necessary. The plant thrives in a pot, shallow perforated pan, or teak-wood basket, and it is important

that whichever is preferred it should be small in proportion to the size of the plant. A very thin layer of peat and sphagnum should be supplied in which to root, and the compost should be made quite firm, and when packing the material around the plant, a few thick crocks placed edge upwards between the peat and the moss will assist the water to pass freely through. Place the plants in the hottest and sunniest position available, with the tops of the pseudo-bulbs almost touching the roof-glass. Very thin shading is required at any time, and then only for a few hours during the hottest part of the day. The plant, until it has become re-established, should not receive much water, but afterwards, and till growth is completed, it must not be allowed to become in the least degree dry. *Dendrobium Bensone* and its varieties, *xanthium* and *album*, are now gone out of flower, and as the young breaks commence to push out new roots when only a few inches high, attention should be given to repotting, &c., doing this in exactly the same manner as I recommended for *D. Phalænopsis*. Similar treatment is required by *D. Parishii*, *D. rhodophygerium*, *D. taurinum*, *D. atro-violaceum*, *D. stratiotes*, *D. lineale*, *D. bigibulum*, *D. strebloceras*, *D. albo-sanguineum*, *D. Johnsonie*, *D. polypheblum*, *D. secundum*, and *D. superbiens*. As soon as the following species, *D. Dalhousianum*, *D. imbricatum*, *D. calceolus*, *D. clavatum*, and *D. fimbriatum*, commence to grow, they should be afforded water abundantly, and kept warm and moist till such time as the terminal leaf is completed. Other species, such as *D. Warlianum*, *D. nobil*, *D. cressinae*, *D. Boxallii*, *D. primuminum*, *D. cretaceum*, *D. lituiformis*, *D. Dominii*, &c., and those of the *D. Ainsworthianum* and *D. splendissimum* sections, now about midway through their flowering season, should, if in health and growing strongly, be copiously watered, otherwise growth will be prematurely matured, and numbers of small useless breaks will be produced.

THE FLOWER GARDEN.

By CHARLES HERRIN, Gardener, Droppore, Maidenhead.

General Work.—The bedding-out of plants for the summer display should be completed as soon as possible. Box edgings may be clipped. It is disadvantageous to do this work earlier, because the young growth resulting after the early cutting sometimes gets injured by frost, causing the Box to remain unsightly for some weeks. Carnations are fast throwing up their flower-stems, and these should be tied to neat short sticks, so as to keep the flowers erect and clean. Sow seeds of *Aquilegia* in boxes or on a border in the reserve-garden, from which they should be transferred to their flowering quarters as soon as large enough to handle conveniently.

General Remarks.—During the past few days the weather in the south has been warm, with genial showers, which will permit of the tenderest bedding plants being planted with safety. The designs of carpet-beds should be worked out true on the surface of the soil; to do this readily and distinctly, fine silver-sand is as good as anything scattered along the lines that are drawn by a pointed stick. If the ground-work, which usually consists of such hardy plants as *Sedum*, *Corastium*, *Herniaria*, *Golden Chickweed*, &c., has been planted some time, the filling-in of the pattern with the tender plants will be a comparatively easy job. A flat and even surface of foliage is not so pleasing in effect as when the system of using "dot" plants is adopted. These may consist of *Chamaeops*, *Palms* of small size, *Dracenas*, and similar subjects. In the flower-bed, in order to encourage free growth, *Pelargoniums* and *Calceolarias* should have their flowers removed for one or two weeks after they are put out into the beds, and the points of untidy long shoots taken out, so as to induce a more bushy habit in the plants. *Calceolarias* planted out some weeks since are now established, and in a condition to withstand drought better than those that were planted later in the spring. A mulch of very short manure, such as that afforded by a spent Mushroom-bed, will be of assistance to these plants if the weather be dry, especially if an occasional application of water be made. All kinds of bedding stuff recently planted will be benefited by a mulch of sifted leaf-mould or cocco-fibre refuse, and affording water towards evening if the weather be dry until the plants are partially established. Any roots of *Dahlia*s still out of the ground should be planted forthwith. The soil for *Dahlia*s should be fairly rich, and where borders are not in good heart, a small quantity of rotten manure should be placed under each root when planting them, just turning it in with the spade, and making it firm before and after planting. Stakes should be

put to the plants without loss of time, or these may be driven into the soil first, and the roots placed close to them. A much of manure will render frequent waterings unnecessary.

Roses.—The Rose-maggot is getting troublesome this season, and resort must be had to hand-picking and squeezing the rolled-up leaves between the finger and thumb. The plants should be examined at short intervals of time for a few weeks for the maggot. Aphides are increasing amazingly, and the plants on walls and in the open beds must be syringed with tobacco or Quassa water, or fuming these with soap-suds at a temperature of 120° to 130°. Frequently syringing the Roses with clear water does good during dry weather, as does an occasional application of weak liquid-manure.

FRUITS UNDER GLASS.

By F. HARRIS, Gardener, Easton Castle, Ledbury.

Melons.—Plants carrying ripe or ripening fruits must be kept drier at the root, or splitting may occur, and the flavour will certainly not be good. Fruits when ripening should be examined, and those which may have to be kept for a few days should be removed from the plants as soon as it is noticed that the rind has begun to open round the stalk, and if this be not attended to with thin-skinned varieties like Easton Castle and Victory of Bath, many of the fruits will burst their rind, and be spoiled in consequence. I have known fruits of Easton Castle, when the soil has been a little too moist during the ripening stage, and the weather very warm, to split all to pieces after being put into the fruit-room.

Succession Melons.—Plants with rapidly-swelling fruits should be afforded some bone-meal mixed with fine loam as a top-dressing to the hillocks, which will make a marked difference in the fruits in a few days. Be careful when affording water to the roots not to wet the stems between wind and water, and to use it at a temperature of not less than 55°. Melon plants in flower may be afforded a drier air during the setting period, and the female flowers fertilised daily about noon till the required number of fruits—three to five per plant—are seen to be starting off together; and when this is accomplished, all the flowers may be rubbed off. Let the lateral shoots be pinched back to one leaf each, and thus employ the energies of the plants in the growth of the fruits. Remove the lateral shoots of younger plants till the stem has reached the trellis, doing this sometimes, or the plants will be weakened by the exudation of the sap. Seeds of Melons may be sown once a week if a regular succession of fruits is required.

Tomatoes.—The early plants being now in full bearing, will require pretty constant attention in the matter of pinching out laterals, removing portions of the leaves to allow sunlight to reach the fruits; top-dressing and feeding, and taking the fruit when fully coloured, not allowing fruit to hang till it becomes dark ripe, as this causes loss of size in the remaining fruits, and exhaustion. Tomato plants intended for out-of-door fruiting should be got out as soon as they are properly hardened off. The growing and fruiting season of the Tomato in this country being a short one, only warm positions are found to answer. The plant does very satisfactorily in the open, if it have a warm site, with a wall or building on the north side. Let the soil be made firm, and pay attention to affording water. Shoots of the Tomato for late autumn and winter fruiting under glass may now be sown in heat.

THE KITCHEN GARDEN.

By W. POPE, Gardener, Highclere Castle, Newbury.

Onions.—Autumn-sown Onions are this year showing a tendency to throw flower-stems. Remove these as soon as they appear, and the plants may afterwards be pulled up for early use as required—they will fail to form profitable bulbs. If bulbs are required of extra large size, for exhibition or other purposes, liberal supplies of liquid-manure should be afforded, and the soil around them frequently stirred with the hoe; or if the weather be showery, a sprinkling of some kind of artificial manure will be of decided benefit. Those sown out-of-doors in the spring will now require thinning, and if large bulbs are wanted, thin freely, allowing 9 or 10 inches between each plant, and afford one or two light dressings of guano during showery weather. If ordinary produce and good keeping qualities are desired, the thinning should be much less severe, 2 or 3 inches apart being sufficient if the rows are 12 inches distant from each other. Dust the plants frequently with fresh soil. Where small Onions are in daily demand, it will be

necessary to sow seeds every three weeks through the summer, the supply being kept up through the winter by sowing a boxful occasionally under glass. For this purpose the Queen or the Silver-skin varieties are excellent, being mild in flavour, and of nice colour.

Potatos.—Mould up the tops as soon as these reach a height of 3 or 4 inches, drawing however a little soil up to the stems, a further earthing-up being done when they get higher. If a hoeing be given the land a day in advance, the surface will be in better condition for moulding, and weeds will be cut off. If the land be not rich, a dressing of mixed fresh soot and wood-ashes should be strewn along the rows before the hoeing and earthing-up are performed. The land that will soon be set free by the lifting of the early Potato crop should be levelled, and planted with Cauliflowers, Brussels Sprouts, Savoys, or Brassica of which the plants are then in fit condition for planting. If the weather and the land be dry, afford water both before and after planting. It is best to draw drills for these things, and soak these with water a few hours before setting out the plants.

Carrots.—Another sowing of Carrots may be made, choosing a short Horn variety. The seed may be sown in drills or broadcast, closer than is desirable for a main crop, 6 or 8 inches between the drills, and thinning out to 3 inches apart in the lines, affording enough space. Thin the plants before they spittle, and keep the beds free from weeds. A slight dressing of soot and salt, given before sowing the seed, acts as a deterrent to grubs and wireworms. If the principal sowing of Carrots has failed, wholly or partially, sow James' Late-mediate variety, this one keeping better in store than any of the short Horn varieties.

Broad Beans.—When the stems of Broad Beans reach 6 feet in height, nip the points, and the Beans will thus be curled, and the pods firm; and if very large pods are desired, thin the latter to three or four on a stem, and apply liquid-manure freely to the plants. Sow a good breadth of Broad Beans are required late in the season, making use of Early Longpod, or Beck's Dwarf Green Gem—an especially useful variety. Broad Beans should be sown on strong soil in good heat, but not freshly manured.

Leeks for the main crop should now be planted, these following the batch raised in warmth brought on for a time under glass. Choose for this vegetable a part of the garden that is rich and deep, such a soil needing no special preparation. In planting, draw deep drills with a hoe at 18 inches apart, and if the soil be dry, apply water to these the day previously, and dibble the plants deeply into the soil at 1 foot apart, but do not fill in round the plants, merely let a small quantity of the fine soil trickle in on to the roots. As the plants grow, the drills may be gradually closed, thus securing a length of blanched stem sufficient for ordinary purposes. Liquid-manure afforded twice or thrice during the summer will increase the size of the plants. Leeks for exhibition should be put out into trenches as the Celery, as previously advised, and be treated similarly. The early crop will require water in dry weather, a much of decayed manure, and to be afforded weak liquid-manure at each alternate watering, or a slight sprinkle of guano-water.

PLANTS UNDER GLASS.

By G. H. MAYCOCK, Gardener, Eaton Hoop Park, Luton.

Tree or Perceck-flowering Citronella.—The time has now arrived when these plants should receive their final watering. For this purpose employ rich soil, half decayed, fibry loam, one-half; the remainder should consist of leaf-mould, rotten manure, lime rubble, and a fair proportion of coarse silver-sand and charcoal. Before commencing to pot, the plants should be freed from insect pests, and in any case it will be an advantage to fumigate them twice in succession; and if red-spider infest them, to dip the foliage in a suitable sort of insecticide. The most vigorous plants may be placed in 7-inch pots, and the others and those latest struck in 5-inch pots. Let the soil be made firm by hand about the old ball, and having afforded water, place them in a greenhouse, cold frame, or shallow pit on a layer of finely-sifted coal-ashes. Keep close for a week, shading if necessary for that length of time; then admit air gradually at first, and increasing the amount daily, and at the end of the month stand them outside.

Nectarine Oleanders.—Plants which were not repotted in the spring may still receive a repotting or tubbing, employing a compost of loam three-quarters, peat one-quarter, and be placed in a light, airy house, and kept slowly growing. It is a mistake to keep

the Oleander in a shaded greenhouse, the shoots that are made therein being green and sappy and unlikely to bloom. The aim of the gardener should be to produce moderately large, short-jointed shoots, which are sure to flower well. Should the blooms not open properly or fall off, a position close to the glass should be afforded the plants. During the growing season Oleanders, being semi-aquatic, require plenty of water at the root. White-scale is their great pest, and red-spider is sometimes troublesome. A Water-soluble sand at 100° used when the plants are at rest will kill the former, and copious syringings with clear water clear off the latter.

Roses in Pots.—As the majority of these plants are passing out of bloom, they may be removed to some spot in the open air where they are not exposed to full sunshine, the pots being sunk in a bed of coal-ashes. Those which are very well rooted will be benefited by doses of weak liquid-manure; and to keep mildew in check, the foliage should be dressed once a week with the following mixture:—To 2 lb. of soft-soap add one quart of rain-water, and boil slowly for twenty minutes, then add two gallons of soft water, place in a bottle and keep securely corked. For use, put half a pint of this mixture to three gallons of water.

General Work.—Remove the side-growths from Tuberoses which are showing flower, and afford the plants occasionally manure-water; those not pushing up flower-spikes should be kept on the dry side, syringing them, however, once a day, in order to check the increase of red-spider. A stock of loam of two sorts, light and heavy, should be carted in and stacked. Maintain a moist atmosphere in the Palm-house, and afford water abundantly at the root, but the drainage should be in good order, or a soddening and souring of the soil will take place; and syringe the plants hourly every day, morning and afternoon. Seedling Geraniums should be repotted and placed in a cool-house on a moist cool bottom.

THE HARDY FRUIT GARDEN.

By H. W. WAIN, Rayleigh, Essex.

Pruning of Wall Trees.—Simple as this operation is, the successful fruiting of a fruit-tree greatly depends upon the manner in which the operations are carried out. It is very essential for the gardener to possess definite notions of the end in view, and how to obtain the formation of a healthy fruitful tree in a reasonably brief space of time, by the removal of unnecessary shoots, and the retention of a sufficient number, and at such a distance from each other as will admit of their being perfectly ripened. The crowding of the shoots is recognised by the best gardeners as being a evil which must always be guarded against whatever be the kind of fruit tree. Any succulent gross shoots should be clipped at the point, or better cut back to the last sub-lateral, which has the effect of diverting the sap to the weaker shoots and strengthening these. In the case of the Apricot, Pear, Cherry, Plum, and espalier Apples, the fore-right shoots should be pinched back whilst soft to within 6 inches of their place of origin; standard trees should also have the points pinched out of luxuriant shoots, the superfluous growths being pinched back to within 2 inches of the base, which operations have the effects of preventing the crowding of the crowns with spray, and of causing the formation of fruit-buds.

The Peach and Nectarine and Marlo Cherry.—The fruit-trees demand the same kind of summer treatment, the young shoots should be laid in through the shoots of last year, keeping them in position with short straight twigs; the fore-right shoots should be pinched-in severely, and terminal growths secured somewhat loosely in position with nails and shreds, or with raffia. The current year's shoots in young trees should be trained rather wide apart at the proper angle on either side of the central line, so as to enable the given space to be furnished within the period of two or three years on the extension system of training.

The Fig.—In the case of the Fig, the shoots which the gardener recognises as not being wanted for bearing fruit, or budding on the tree, should be cleared out away before they acquire strength, and the desired number of leading shoots secured in their proper direction. The points of any very robust shoots, when these have reached 15 inches, and those of weak ones when 2 feet in length should be pinched-out, which will have the effect of balancing the current year's growth, by temporarily diverting the flow of sap to the weaker shoots.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on ONE SIDE ONLY of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction in these pages, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, JUNE 15	Royal Horticultural Society, at Drill Hall, Ryde Horticultural and Rose Show.
WEDNESDAY, JUNE 16	York Floral Fête (3 days).
THURSDAY, JUNE 17	Linnean Society.
FRIDAY, JUNE 18	National Rose Society's Southern Show, at Portsmouth.

SALES.

TUESDAY, JUNE 15	Site of the Westrop Collection of Orchids, by order of G. O. Sloper, Esq., by Protheroe & Morris.
WEDNESDAY, JUNE 16	Specimen Palms and Ferns, at Protheroe & Morris' Rooms.
FRIDAY, JUNE 18	Imported and Established Orchids, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE FOR THE ENSUING WEEK, deduced from Observations of Forty-three years, at Chiswick.—60° 9'.

ACTUAL TEMPERATURES:—

LONDON.—JUNE 9: Max., 54°; Min., 50°
 PLYMOUTH.—JUNE 9 (6 P.M.): Max., 59°; Jersey; Min., 47°; Aberdeen.

In anticipation of the sixtieth anniversary of the accession of Her Majesty, now close at hand, we publish this week several articles relating to the changes that have occurred in horticulture during the Queen's reign, and we give sundry illustrations of plants named in honour of the Sovereign. The enormous development in horticulture, whether for purely decorative or for useful purposes, during the past sixty years is a matter of general observation. What was the luxury of the few has become the necessity of the many. This in itself is a striking testimony to the peaceful spirit of progress that has characterized the reign as a whole. A vast extension of Orchid culture in particular has taken place since Her Majesty's accession. If some plants of this family are priced in hundreds of guineas, others, almost as beautiful, may be had for a shilling or two, and may be grown at as little cost as a Pelargonium. Palms are hawked about the streets on costermongers' barrows, and the windows of the humblest can be brightened at the lowest cost.

Of the plants of which we now give illustrations, we must first make mention of the Rose "Her Majesty" (fig. 143), one of the finest of the late Mr. BENNETT'S seedlings, and for the opportunity of illustrating which we are indebted to the courtesy of Mr. MAWLEY, one of the Secretaries of the National Rose Society. It was grown under glass, and flowering thus prematurely, the bloom is not of the full size.

The Gloxinia issued by Messrs. SUTTON under the name of "Her Majesty" (fig. 142, p. 381) is the noblest white Gloxinia yet raised. In

form, substance, purity, it ranks foremost of its class. Messrs. SUTTON & SONS, Reading, kindly gave us the means of figuring it.

The "Victoria Regia" is now well known to visitors to Botanic Gardens as the noblest and most remarkable of Water-lilies. In this country it is grown in tanks under glass, but in the United States it is grown in heated ponds in the open air, as shown in an illustration furnished by C. NASH, Esq., which we shall reproduce on another occasion. At Singapore no artificial heat is needed, as may be judged by the woodcut in the volume for February 16, 1878, p. 209. (See fig. 139, p. 378.)

Among Orchids named after HER MAJESTY, one is called Queen Empress (see fig. 139, p. 378). It was shown at the Temple Show by Messrs. LINDEN. It is one of the finest of the varieties, and received an Award of Merit. It is a perfect flower of good form and very fine colour, though in the richness of the purplish-crimson of the lip, C. M. Moortbeekensis and two or three of the other varieties were perhaps superior to it.

"Queen Victoria" is the name bestowed upon a very beautiful form of *Odonoglossum crispum*, shown at the Temple by Messrs. HUGH LOW & CO., with bold flat segments heavily blotched with purplish-brown, and with the white three-lobed lip similarly marked and fringed (see fig. 140).

"Victoria" Daffodil was exhibited at the Spring shows by Messrs. BARR & SONS, and when we say that it surpasses Empress and Hors-field, little further is needed in the way of eulogy. The segments of the perianth are spreading, unusually broad and pure white, whilst the bold corona is of a delicate yellow, and frilled at the margin.

Victoria Nectarine (fig. 144) is one of the acquisitions of Messrs. RIVERS, described in a note on p. 380.

** In our next issue we shall, by special permission of HER MAJESTY, give illustrations and descriptive notes, necessarily brief, of the gardens at Buckingham Palace, not previously visited for the purpose for nearly a quarter of a century, Frogmore, Osborne, and Clarendon, together with notes on some of the memorial trees planted by the Queen on different occasions.

LINNEAN SOCIETY.—At the evening meeting, which will be held on Thursday, June 17, at 8 P.M., papers will be read:—1. "On the Distribution of *Prunella elatior*, Jacq.," by Mr. MILLER CHRISTY, F.L.S. II. "On the *Acaei* collected by Mr. H. FISHER, Naturalist of the Jackson-Harmsworth Polar Expedition, at Cape Flora, Northbrook Island, Franz-Josef Archipelago, in 1896," by Mr. A. D. MCCAULEY, F.L.S. III. "Further Observations on *Stipules*," by Sir JOHN LUBBOCK, Bart. IV. "On Minor Tension Lines between Plant Formation," by Professor CONWAY MACMILLAN (Univ., Minnesota).

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Fruit and Floral and Orchid Committees will be held on Tuesday, June 15, in the Drill Hall, James Street, Westminster. A lecture on "The Physiology of Plants" will be given by Prof. S. H. VINES, F.R.S., at 3 o'clock.

ROSE SHOW FIXTURES FOR 1897.—The following additional Rose-show dates are kindly sent us by Mr. E. MAWLEY. Previous lists appeared in our issues for March 20, April 10, and May 15 last:—June 16 (Wednesday), York (three days); 30 (Wednesday), Farnham; July 6 (Thursday), Diss; 8 (Thursday), Bedford, Farnham; 10 (Saturday), Manchester; 31 (Saturday), Liverpool (two days).

HORTICULTURAL CLUB.—The usual monthly dinner and conversation will take place on Tuesday

evening, June 15, at 6 P.M. The subject for discussion will be "A proposed Memorial to Dr. ROBERT HOGG."

HAMBURG EXHIBITION.—We are informed that a gold medal and a prize of honour of the value of 1000 marks (£50) has been awarded to Mr. ANTHONY WATERER, of Knap Hill Nurseries, for Rhododendrons, &c.

JUBILEE COMMEMORATION METHODS are bewildering in their variety. Perhaps the following example is as worthy of imitation as any:—Messrs. ED. WEBB & SONS, Royal Seed Establishment, Worsley, Stourbridge, intend to give to the whole of the children of the district (nearly 2000) "a substantial tea and medals to commemorate the event."

MESSRS. SUTTON & SONS, READING.—On Tuesday, June 1, a dinner was given by Messrs. SUTTON & SONS, Reading, to the whole of the *r employes*, to commemorate the entering into partnership of Mr. MARTIN HUBERT FOQUETT SUTTON, the eldest son of the senior partner of the firm—Mr. M. J. SUTTON. The total number of the *employes* and their wives who sat down to dinner in one of the spacious rooms of the seed establishment was about 500. The tables were decorated with cut flowers and plants in pots, and the *menu* was of the best. The chair was taken by Mr. MARTIN JOHN SUTTON, supported on his right by his father, Mr. MARTIN HOBBS SUTTON, and on his left by his son, Mr. M. H. F. SUTTON.

ISLE OF WIGHT HORTICULTURAL IMPROVEMENT ASSOCIATION.—The monthly meeting of the Association was held on Saturday, June 5, at Sandown. Dr. J. GROVES, B.A., J.L., in the chair. An excellent paper contributed by Mr. ALFRED OUTRAM on "The Progress of Horticulture in America" was read by Mr. C. ORCHARD. The paper, which was highly appreciated, was accorded a vote of thanks. Exhibits of various kinds came from a number of gardeners residing in the Island.

DOUBLE WHITE ANEMONE "THE BRIDE."—Messrs. E. H. KREMLAGE & SON of Haarlem have favoured us with cut specimens of this pretty variety, which originated in their nurseries as a sport from the well-known single Anemone of the same name. The flowers, when they first open, are of a greenish tint; but as they expand, they form a fully double, pure white flower.

TERATOLOGY.—M. CASIMIR DE CANDOLLE, in discussing the relations of teratology to the problems of evolution, comments on the treatments of Dr. MASTERS and Professor PENZANCE. M. DE CANDOLLE distinguishes between those forms which he calls ataxinomic, which have no relation to any normal condition, and those variations which are represented normally in other species, and present an analogy to specific differences. These, which M. DE CANDOLLE calls taxinomic variations, have taken a part in the evolutionary progress. It is obvious (says M. DE CANDOLLE, in conclusion) that the following inferences may be drawn:—If the teratological variations of the floral organs have taken any share in progressive evolution, those whose progress has resulted in the present complex forms are now the most uncommon, while those monostrosities which are now the most frequently met with indicate, at any rate in the case of phanerogamic plants, a tendency towards the primitive simplicity of conformation (reversion). Consequently, if the progressive taxinomic monostrosities of the flower were not formerly more frequent, and more especially if they were not more varied than they now are, they would have been powerless to produce, by the sole agency of natural selection, that evolution which is supposed to have resulted in the production of the most highly-developed forms of the present day.

PRESENTATION TO MR. INGLIS, OF HOWICK.—Recently Mr. D. INGLIS, who for the last twenty-two years has acted in the capacity of head gardener to Earl GREY of Howick, and who during that time has made himself extremely popular, not only at Howick, but in the district generally, was made the

FIG. 113. ROSE "HER MAJESTY" (COLOUR PALE ROSE). (SEE P. 378.)

recipient of a handsome inlaid rosewood cabinet by the parishioners of Howick and other friends on his leaving the district to take up the duties of head gardener to his Grace the Duke of Buccleuch, at Drumlaurie Castle, in Dumfriesshire. The presentation took place in Copley Hall, and Mr. J. H. MANSFIELD presided. Mr. and Mrs. INGLIS have also been the recipients of a silver tea-service from the Earl and Countess GREY; and a few days before leaving Howick Mr. INGLIS received a letter from Earl GREY from Fort Salisbury, in Mashonaland, expressing sincere regret that he should not find Mr. INGLIS and his family at Howick on his return. Mr. INGLIS has been succeeded at Howick by Mr. ACKROYD, from Bevingborough Hall Gardens, near York.

POSOQUERIA MACROPUS.—From Messrs. W. BALCHIN & SONS, Hassecks Nurseries, Sussex, come two trusses of this attractive stove-plant, also known as P. longiflora. The plant, we are told, bears thirty fine trusses of long, tubular, white, fragrant flowers. That it is not more grown is, as Messrs. BALCHIN say, a matter for surprise, as it is certainly one of the most handsome of stove-plants. A figure of it was given in our columns on May 9, 1896, p. 587.

STOCK-TAKING: MAY.—It is worthy of note that, notwithstanding the very larv' work now going on in the matter of juktilation, the busy British lives of industry find time to beat the record in the matter of imports, and to record a fair balance in the matter of exports. Thus, amongst other things, the Trade and Navigation Returns for the past month show that the imports foot up a balance of nearly three millions sterling as compared with May, 1896—or, say, £36,336,348 for the past month, as against £33,349,988 for the same period last year. The increase in the five months of the present year over the same period last year is placed at £7,895,740. As to the increments of the past month, they are to be found under nearly every sectional heading—decreases being comparatively trifling. The usual excerpts from the "summary" table of imports are as follows:—

IMPORTS.	1896.	1897.	Difference.
Total value ...	£33,349,988	£36,336,348	+2,986,360
(A.) Articles of food and drink—duty free ...	19,628,363	12,231,157	+1,602,524
(B.) Articles of food and drink—dutiable	1,716,187	1,967,998	+281,771
Raw materials for textile manufactures ...	5,615,257	5,160,092	-455,165
Raw materials for sundry industries and manufactures	3,483,685	4,143,172	+660,087
A) Miscellaneous articles ...	1,141,078	1,072,164	-68,914
(B.) Parcel Post ...	58,267	71,511	+13,244

However much disquiet may be felt in the matter of foreign relations, no such effect seems to be worth noting in respect to the general volume of trade. By the way, there seems to be but little doubt of the good effect of bringing together in London all the dignitaries of our Colonial empire.

IMPORTS.	1896.	1897.	Difference.
Fruits, raw:—			
Apples ... bush.	88,252	123,985	+35,676
Cherries	7,170	56,278	+49,108

Potatoes	550,959	385,440	-145,519
Vegetables, raw, unenumerated ... value	498,192	416,244	+60,052

EXPORTS.

Last month we took occasion to note that soon the then reported decrease would be wiped off; this hope has not been quite realised, but the amount has been

reduced by nearly half a million, or to £265,224. Perhaps, as some suggest, manufacturers have been so busy on the "homo" account as to prevent them filling foreign orders to their full extent; at any rate we are informed that, as with homo orders, so with those for both colonies and foreign countries, both will have to be satisfied for the present with what they can get—just as it was for some time last year in most textile fabrics. Recently we had occasion to call attention to the good work performed by consular agents abroad. There is occasion this month to notice a report connected with the "management" of German trade with Baltic ports—the methods employed in order to oust the British trader from that portion of the globe. One almost naturally thinks of "Nelson and the North" in this connection, and it may be as well to note that our traders will find in Copenhagen every possible accommodation for spirited trade at very low figures, and outside of this will be found a kindlier feeling towards ourselves than is shown to any other class of manufacturer's agents—a knowledge that "goods" outlast "bills" by ever so long; and that is saying something. The total value of exports for May is £19,322,116, against £18,835,243—an increase on the month of nearly half a million sterling.

SARACA INDICA.—This plant, perhaps better known under the name of Jousiea Asoca, forms a low, erect-growing tree, native of the Himalayan region, Ceylon, and Malaya, and occurs up to an altitude of 2000 feet in Kumaon. This tree is dedicated to Kama, the Indian God of Love, and is sacred to the Hindus, who know it under the name of Asoka, which means "tree without grief," or "free from pain." The rich orange-coloured blossoms, in the form of dense, sessile, corymbose, axillary panicles, with reddish bracteoles, are highly fragrant, and are employed in India for table decoration. The tree is described as a most beautiful one when in full bloom, and is usually planted in the neighbourhood of temples. The bark contains gallic acid, and is extensively used by native physicians in uterine affections. A plant of this has been in bloom in the Palm-house, and it also forms the subject of one of Miss North's paintings in the gallery at Kew. J. M. H.

IRIS GATESII.—Messrs. WALLACE & Co., of Colchester, obligingly forward us a bloom of this species, exhibited by them at the Temple Show. It is one of the largest and most remarkable of the bearded Irises, of a greyish or cream colour, thickly bestrewn with minute brownish spots. A full-page illustration was given in our columns on July 5, 1896.

AN EXHIBITION OF BRITISH-GROWN FRUIT will again be held at the Crystal Palace under the auspices of the Royal Horticultural Society. Though some slight delay was experienced in obtaining the £100 towards the prize-money, that the society stipulates as a necessary condition to holding the show, this amount has since been subscribed, and from the schedule before us we observe that the dates fixed are those of September 30, October 1 and 2. In the wording or arrangement of the classes we note but little deviation from that adopted previously, that upon the whole has been satisfactory, though it affords little scope for individual exhibitors to display their produce in a decorative manner. To prevent disappointment on the part of exhibitors, the schedule includes a list of dessert and culinary varieties of Apples and Plums, and a list of culinary Pears. We may add that the cost of the gardeners' luncheon upon the first day has been reduced to 3s. for each person.

PUBLICATIONS RECEIVED.—*Bulletins of the Botanical Department, Jamaica*, for February and March. The earlier of these two issues includes papers on Soil Ferments important in Agriculture, the Spraying of Plants, Fungous Diseases of the Grape, Fungicides, Jute, and other subjects; the March Bulletin deals with: Mannes and Oranges, Mannes and Coffee, Report on Sugar Cane, Grass-Firing, Collecting Juice of Papaw, and similar topics.

—*Agricultural Gazette of New South Wales, March.*—*Queensland: Past and Present.* This is an epitome, by Mr. THORNTON WEDDON, of the resources and development of the colony up to 1896. This volume is issued under official sanction, and is intended to furnish such information as is otherwise only to be found scattered about in more voluminous and general treatises. The value of the book before us may be inferred from the fact that the contents are devoted to a survey of the geography, history, constitution and government, population, law, defence, production, trade and commerce, and equally important statistics relating to Queensland. The appearance of the *Bulletin* is especially interesting this year, when our attention is everywhere attracted to the progress of the last half century.—*Report of the Viticultural Work during the Seasons 1887-93.* This volume is issued from the University of California, College of Agriculture, and should prove valuable to present and intending Vine-growers.—Southern California Acclimatizing Association sends a *General Catalogue and Garden Guide* for May, which includes "Summary Description, Degree of Hardiness and Hints to Culture of 1,500 sorts of Plants." The *Haulbook* treats of Palms and Cycads, Bamboos, decorative plants, fruit-bearing and economic plants, trees and shrubs suited for various positions, pot-grown, climbing, bulbous, and other plants, Californian native plants, and other varieties. The *Catalogue* comes from Santa Barbara, California, U.S.A.—*Resistant Vines*, from the University of California, College of Agriculture. This is an appendix, written by Mr. A. P. HAYNE, to the *Viticultural Report*, which we noticed just above.—*Bulletin of the Agricultural Experiment Station, Baton Rouge, Louisiana.* Devoted to a paper on Leguminous Root Tubercles, by Mr. W. R. DODSON.—*Prospectus of the Queensland Agricultural College, February.*—*Annual Report of the Agricultural Experiment Stations of the Louisiana State University for 1896.*—*Studies of American Grasses* (U.S. Department of Agriculture) includes, I, New or little-known Grasses, by F. LAMSON SCHEIBER; and 2, Leaf-structure of Jouvea and of Eragrostis obtusiflora, by Miss E. L. OGDEN.—*Agricultural Journal, Cape of Good Hope.*—*On Insects collected by Dr. Abbott on the Seychelles, Aldabra, Gloriosa, and Providence Islands*, by MARTIN L. LINNELL (Smithsonian Institution, U.S. National Museum).—*Florists' Exchange, New York.*—*Tropical Agriculturist.*—*American Florist, New York.*—*Gardening, Chicago.*—*Führer durch die Gartenbau-Literatur*, LUDWIG MÜLLER, Erfurt.—*Wienur Illustrirte Garten Zeitung.*—*Motter's Deutsche Gärtner Zeitung.*—*Les Espèces du Genre Anagallis*, par M. E. ROZE: Extrait du *Bulletin de la Société Mycologique de France.*—*Tijdschrift voor Tuinbouw, Twealfde Aflevering.*—*English Mechanic and World of Science.*—*Mothers and Daughters.*—*Nature Notes.*—*Lindens, February to March.*—*The Orchid Album*, vol. PLANT PORTRAITS.

CELOGYNE MASANGRANA, Rehb. f. in *Cons. Crum.*, 1878, p. 684; *Lindley*, t. XLVIII.

CHAMA LAFAYETTE, Thuret et de Willeman.—A white-flowered species from the Congo State. *Revue de l'Horticulture Belge*, May.

CYPRIPEDIUM LAWRENCEANUM VAR. *VERIDIS*.—A form with the standard marked with green stripes on a white colour, lateral petals half-green. *Lindley*, t. XLVII.

CYPRIPEDIUM × *MASSEIANUM*, Weathers, in *Gard. Chron.* (1893), XIV, p. 257, c. ic.; hybrid between *superficiaria* and *Bolleschilliana*; *Lindley*, t. XLVII.

DENDROBIUM JOHNSONÆ, *Gardens*, April 10.

DRAENA ARBOREA. (2).—Tall, Palma-like species, with a terminal tuft of lanceolate leaves, surrounding a central, much-branched, pendulous panicle; fruits globose, red, of the size of a small Cherry, *Gardens*, t. 1438.

DRAENA GONZALEZIANA, *Gardens*, April 23.

LOBELIA SPALDINGII, *Gardens*, Monthly, April.

ODONTOGLOSSUM CRISPUM VAR. *SPECTABILIS*, Lind.—A strong variety, with flat, broad segments of a white colour, with a large central reddish-brown blotch; disc of lip yellow, anterior portion spotted. *Lindley*, t. XLVII.

ODONTOGLOSSUM HENSEWILLIANUM VAR. *GRANDIFLORUM*, Rolfe, in *Gard. Chron.*, s. s., VI, p. 67; *Lindley*, t. XLVI.

PELÆO SOUVENIR DE LEROU-DURAND, *Bulletin d'Arboriculture*, &c., April.

PRIMULA QUERCINA, *Gardens*, May 1.

VANDA SANDERIANA, Rehb. f., *Lindley*, t. XLVIII.

THE GARDENS AT THE VICTORIAN ERA EXHIBITION, EARL'S COURT.

The directors of this undertaking have secured the services of Messrs. John Laing & Sons, nurserymen, Forest Hill, to lay out their grounds at Earl's Court. They have carried out the task in a most pleasing manner, and in harmony with Mr. Jure Kiraly's ideas. The western gardens, where over 5,000 zonal Pelargoniums (chiefly Henri Jacoby and others) have been planted, are exceedingly effective.

Improvements have been made in the lawns surrounding the Welcome Club, Messrs. Laing having here placed a group of fine named varieties of Rhododendron hybridum. A prominent position near the "Panorama" is pleasantly furnished with beds of Koses, Ivy-leaf Pelargoniums, with an undergrowth of Musk, and two beds of the Mrs. Henry Cox Pelargonium.

Crossing the bridge, the radiant "Queen's Court Gardens" is reached. Here the bedding-out is of a massive and effective character. Small groups of Pelargoniums backed with shrubs stand in each corner of all the stairways. Around the tower there are long borders of Henri Jacoby, salmon-coloured and white Pelargoniums, with scroll edgings; and opposite to these are two massive round beds filled with Pelargoniums in variety. Appropriate scrolls surround the beds, planted with carpet-bedding plants representing a royal crown, V.R., 1887, &c. In this vicinity there are various effective designs. The walk from the West Prompton entrance is flanked by massive beds of Pelargonium Raspaill and white-flowered Marguerites, edged with Golden Feather and dwarf blue Lobelias. *J. B.*

ORCHID NOTES AND GLEANINGS.

ORCHIDS AT WOODHATCH, REIGATE.

ALTHOUGH Mr. T. B. Hayward does not send up groups of Orchids to the Temple Show, it is not that he lacks them. Woodhatch lies just a little out of the beaten track of wayfarers, but a visit there, especially by orchidists, and particularly at this time of year, is amply repaid, for the collection under Mr. Salter's care is not only a very fine as well as a comprehensive one, but is throughout in splendid condition. Formerly, in one or two houses, owing to the lack of atmospheric motion under the stages, some things did not thrive so well as could be desired. Now that the stages are open the effect is remarkable,

and every plant in these houses wears an aspect of health that may well be described as robust, and clean as well can be.

The first house entered is of moderate dimensions, and is but a lobby as it were to the Orchid galleries beyond. Here *Odontoglossum crispum* luxuriates in variety, and especially noticeable is *Masdevalla Chirmeri*, one of the most striking of the whole family. Beyond is a house chiefly filled with *Miltonias*, of which there are many superb varieties. The most striking of all is that rare and splendid form *Daisy Hayward*, carrying two noble spikes of flowers. These are of great size and substance, while, just slightly tinged with rose, which as the flowers age disappears, and they become pure white. It is, indeed, a gem. Very fine, too, is *Miltonia Cobbiana*, having flowers nearly white, and of great size. Much deeper in colour than are the flowers of the type, are those of *M. radiata*, which are quite of a bright rosy-red. Some forms have lesser flowers, but beautiful tints; indeed all, and the variety is considerable, are of high class form and quality. *Dendrobium suavisimum*, both in this and in other houses, is flowering finely. The third house is largely devoted to *Phalaenopsis*, of which most beautiful, as well as pure in colour, are *amabilis grandiflora* and *Schilleriana*, all having fine spikes of bloom, and leafage beautifully marked and very stout. Then follows a long house devoted to *Odontoglossum* and *Masdevallas*, the paler tints and graceful forms of the crispum spikes combining most effectively with the small shield-like and brilliantly coloured spathes of the latter plants. Of *O. crispum* there are some grand forms, the flowers not only exceptionally large and stout, but also prettily fringed on the edges. Very few of these have varietal names, yet, if shown at the Drill Hall, they would probably receive high honours. In any Orchid album the best of these fine forms should be represented. The lack of names renders special or individual reference out of the question. They want to be seen to be appreciated. *Oncidium superbiens*, having two huge spikes of bloom, is a very fine feature. Of *Masdevallas*, *Veitchi*, *Harryaea*, *igneae*, *Schlimi*, and *Chelsoni*, are in full bloom, and exhibit exceedingly rich coloration. These are all, of course, well known, and require no description.

Then follows a long house filled with *Cypripediums* on the front stages, and *Vandas* and *Aerides* at the back. Of the former, *C. Lawrenceanum*, carrying many flowers, is very fine; *Curtisii* is good, so also is *villosum*, with its oddly-coloured brownish-yellow flowers. A very beautiful form is *C. ciliolare*; and of hybrid production, a very interesting variety is *T. B. Hayward*. *Exul* is a striking form, with its long dorsal petals; so also is *grande*, the petals hanging down some 10 inches in length. *C. leucorrhoda* is a very beautiful variety, and *Victoriae Maris* is extremely interesting. There is also in the house a splendid batch of *C. bellatulum*, some varieties having not only unusually fine but heavily-spotted flowers of great beauty; these are in 9-inch pans, and the plants are of corresponding breadth. *Thunia alba* and *T. Bensonei*, the flowers having rich violet shading, are prominent objects on the back stage, and in the succeeding house *Thunia Marshalliana*, flowers pure white, with large orange lip, is a lovely thing. Here is a large batch of seedling *Cattleyas*, *Dendrobiums*, &c., the products chiefly of crosses made by Mr. Salter. These are all in thumbs and small 60's, and are thriving admirably. Really Orchid-raising from seed seems so little difficult that should native habitats fail, our home stocks may be in time maintained by home-raising from seed. This house contains chiefly a large batch of *Dendrobis*, many of them grand pieces, and just now putting on splendid growths.

Lastly, comes a farther long house, filled with *Cattleyas*, chiefly *C. Mossie*, and including numbers of grandly flowering superb varieties; *C. bulbosa*, *purpurata*, *russelliana*, and many others, glorious to behold. *C. Mendell* and its forms have been fine, but are now getting over. *Vanda coruella* is represented by capital pieces. Altogether, Mr. Hayward has not only a large but also a representative collection of Orchids, of which any gentle-

man may well be proud, and the culture and treatment furnished could not be excelled.

Cannas seem to be highly favoured, as in another house these in large pots are very effective—indeed, may be described as brilliant. Very beautiful varieties are *Franceque Morel*, orange-crimson; *Comtesse d'Estoisle*, yellow, spotted red; *Progression*, orange, with rose spots; *Sophie Buchner*, orange-red; *Antoine Bartrone*, orange, dark spots; *Souvenir de Jeanne Cheraton*, rich crimson; *President Chardon*, orange-buff; *Kaiser Wilhelm*, rich reddish magenta; and several others.

Trees *Carnations* are largely represented; and a house filled with huge, grandly-grown herbaceous *Calecolarias* in rich variety shows that flower culture is representative; whilst outdoor *Roses* are splendidly done by thousands, and are in their season a wonderful feature. *A. D.*

BELGIUM.

ON May 29 I visited the Château de Botelaer at Deurne, near Antwerp, and there, among the many Orchids in flower in the houses I noticed the following:—*Miltonia vexillaria*, in a pot 8 inches across, had 30 spikes, and 220 flowers; *Lycaste Deppel*, with very pure white petals; *Cochlioda Nötzianna*, flowering freely and abundantly, one specimen had two branches with twenty flowers on each, massed in a wide-spreading truss measuring 3 inches across; hundreds of flowering plants of *Mesopidium vitellinum* majus; a fine *Odontoglossum Skinneri*, the lip violet-lilac, and petals dark chocolate brown, and many plants of *O. crispum*.

In another house was *Dendrobium suavisimum*, the lip bearing a brownish-red spot; *Nanodes Melusse*, well flowered; *Schomburgkia tibicinis*; a fine *Angulou Ruckeri* and *Odontoglossum citreum*, with all the parts of the flower spotted. The nice, fond of eating the succulent flower-stems of this species, have wrought much havoc in the house. In the *Cattleya*-house were many fine specimens of *C. Mossie*, *Mendell*, *Warneri splendens* and *luticola*; *Lælia grandis* and *purpurata*; *Vandas* and *Agrocaracis*; also a fine collection of *Cypripediums*, including *C. Salieri*, *exul*, *Thoussoni*, *Kimballianum*, and *ciliolare*. *Ch. de B.*

WOBURN FRUIT-FARM.*

"ALTHOUGH the endeavour to derive pecuniary profit from the undertaking has never been taken into account, yet the commercial aspects of fruit-growing receive consideration at the farm. Certain plots of ground have been planted in ways suitable for farmers, market growers, and cottagers respectively, and careful accounts are kept of each plot separately, so that the cost and profit of the various methods of cropping the ground may be ascertained.

Every investigation, however abstruse or scientific in its nature, must be considered as having a prospective practical value if it tends to increase our general knowledge of the subject, and in this light may be regarded a large number of the questions now under investigation at the farm. There are, for instance, sixty experiments on *Apple-trees*, in which different methods of planting, pruning, manuring, &c., are being tested, and the following may be mentioned as an instance of one of the most striking results already obtained. It is a common practice in farmers' orchards all over the country to allow grass to grow around the young trees, but it has been proved by our experiments that this practice reduces the amount of growth of the trees to one-eighth of that of similar trees round which the soil has been kept open.

Apple-trees are naturally those which occupy the greater part of the farm, the *Apple* being the most important fruit for English growers; but the other fruits which are hardy and thrive out of doors in England are also being investigated, and all our experiences hitherto goes to prove that the failure of anyone embarking on fruit growing in the neighbourhood would not be due to any deficiency of crop. This is

* Extracted from *A Great Agricultural Estate*, pp. 166-171. Noticed in our columns, p. 361.

important, inasmuch as the ground on which the farm is situated possesses but few apparent advantages for fruit growing. It has a gentle slope to the south-west, but is much exposed to wind; the soil is rich, but is heavy and shallow, there being only about 9 inches of good soil, below which there is a bed of very stiff clay. The ground is mostly low, with a

furnish a supply to those tenants on the estate who wish to embark on fruit-growing, or to fill up vacancies in existing orchards. There has not, at present, been time enough to develop fully the functions of the fruit-farm in relation to the estate, but it is proposed that details of all the orchards on the various estates, whether in Bedfordshire or elsewhere, should be

the interest of the estate, that the work of planting and of tending the trees for the first year should be carried out by experienced persons; and so far as our present experience goes, we have found the tenants very ready to avail themselves of these advantages.

Use will probably be made of the fruit-farm for educational purposes in connection with the County Council farm school; and it is also proposed, eventually, to give evening or other lectures on fruit-growing for the benefit of all who may care to attend. It has been considered advisable, however, not to start any lectures of this sort until we shall have obtained from personal experience a better knowledge of the commercial prospects of fruit-growing in the district, lest we should induce some to embark on an industry which could not be conducted successfully. For the same reason we have been careful to avoid even an appearance of advocating fruit-growing for the farmers, and consider that the initiative should be left entirely to them.

At present the fruit-farm extends over twenty acres, and nearly the whole of the ground is already planted. The planting, however, has not been carried out to any great extent in that close manner which would be necessary for commercial purposes, for many of the experiments will not be complete till the trees have obtained maturity, and till they occupy much more space than they do now, and any cropping of this space would modify the soil in a manner which might render the results of the experiment doubtful. For this reason alone, independent of the expense of the weighing and measurements and other scientific work necessary in experiments, the farm as a whole could never be expected to yield a money profit, or even to pay its expenses; indeed, it is probable that it will cost annually about £500, without charging interest on the capital expenditure. This latter has been about £3300.

The staff includes a resident manager, and on the average seven or eight men and boys, the amount of labour required varying considerably with the time of year.

Besides the manager's house and the necessary sheds, there is a garden-house in the ground, which is used for exhibition, lecture, or reception purposes. A store-room for the fruit, and a new office, are in course of erection."

HOLLAND.

HORTICULTURAL NOTES.

THE following horticultural notes were taken during a recent visit to Holland.

Boterdam Zoological Garden.—Here a new conservatory has been built, measuring about 82 feet long by 40 feet wide, and 35 feet high; this is but part of a projected building, which, when completed, will be 130 feet long, with two aisles 32 feet long connected with the principal erection by low houses 60 feet long by 10 feet high.

In the completed building I noticed *Balanium antarcticum* with a stem 22 feet high; *Todea barbara*, 3 feet in circumference; *Knightia excelsa*, *Banksia*, *Cussonia*, and others. Among the Palms in the winter garden, I would mention *Livistonia sinensis*, and *L. oliviformis*, with stems 9 feet high; *Scaevola elegans*, 18 feet; *Cocos flexuosus*, and *Washingtonia robusta*. In the aisles of the winter-garden are *Encephalartos Lehmanni* of great beauty, and *Strelitzia regina*. The *Victoria regia* house is beautified with *Cyperus*, *Paratropia*, and *Croton*; also *Sobralia macrantha* in a tub 4 feet across. The Orchids are numerous, and flowering well; it is hoped that the Administration will allot a special house for them.

The principal ornaments of the Palmarium are *Kentias Lindeni* and *Luciani*; also *Theophrasta macrophylla*, *Strelitzia Nicolai*, and *Curculigo recurvata*. The Garden celebrates the fortieth anniversary of its foundation this year. The Director is Dr. J. Buttikofer, known for his travels and explorations in Liberia and Borneo; the head gardener is M. J. Wilke.

FIG. 144.—NECTARINE "VICTORIA." (SEE P. 384.)

(Colour of the fruit greenish-yellow, except on the sunny-side, which is crimson.)

brook running along the bottom of it, and the land is retentive of moisture, and in wet weather becomes quite unworkable; indeed, as an arable field, in which condition it had been for many years previously, it had acquired an evil reputation, and before its conversion into a fruit-farm, had been allowed to become very foul.

In addition to its experimental site, the farm is utilised as a nursery where trees are being raised to

recorded at the fruit-farm, so that any application for fruit trees on behalf of the tenants may be dealt with by an experienced person, already possessed of full knowledge of the requirements of the case, and the trees will be supplied direct from the fruit-farm, and in many cases planted by, or under the supervision of, the manager. In cases where a tenant, whether farmer or cottager, is embarking in fruit-growing for the first time, it is much to his interest, as well as to

and shape of that of *Echinops Nitro*. The individual flowers kept expanding for a week, and opening nearly at the same time each day, 3.30 P.M., and giving off a most delicious aroma. These flowers shrivel before the morning, and all traces of the aroma vanish till fresh ones expand the next day. Its congener, *D. fragrans*, I have not grown; but it would be hard to excel the above in beauty and fragrance. The flowering of various plants, especially such as have fragrant flowers, leaves a lasting impression. I look back a little lifetime when at the home of my youth I watched the expanding petals of the Victoria Regia, and its great floral fragrance penetrating the air for a long distance from the plant; and I have the same recollections of *Cereus grandiflorus* (Queen of the Night), and of many other plants, hardy or semi-hardy, and others of great beauty, as, for instance, *Ambrosia nobilis*, &c. (*Geo. Bolas*.)

BULB DEFLORATION IN THE REGENT'S PARK.—About a time since I had an opportunity of seeing some of the Tulips and Hyacinths being lifted from the beds in the Regent's Park, and in the bulb-room I also saw how they were stored away to finish their ripening, as stated by Mr. Earley. I may mention that in the case of all the bulbs grown in beds, the flower-stems are cut away as soon as faded; a few days after they are dug up and taken in wheelbarrows to the bulb-room—which is on the same principle as a modern fruit-room, only instead of fixed shelves there are light wooden trays, open at the sides, to admit of a free circulation of air. A layer of very fine ashes in the form of dust, as dry as it can possibly be, is laid in the bottom, then the foliage of each bulb, whatever it may be, is cut away, leaving from 2 to 4 inches of stem; the bulbs are then laid close together in a single layer, without any soil adhering to their roots, and the bulbs, but not the stems, covered with fine ashes; the trays are then put back, and there they remain until late summer, when they are looked over, cleaned, and sorted for planting. The strongest are planted in the park beds for flowering in the following spring; the effects are planted in nursery beds, of which there are many, in an enclosed piece of ground near the Regent's Park College. Here they remain for a year or two until they have grown into size, and large enough to occupy beds in the Park garden. Mr. Jordan contends that there is vital force enough in the bulbs, and in the moisture they convey to the ashes about them, to properly mature them and prepare them for another season's bloom. The proof of this is seen in the magnificent beds of Hyacinths, Tulips, Daffodils, &c. Mr. Jordan is able to produce from bulbs so treated. If by doing so he appears to run counter to some prevailing notions as to the action of the foliage in producing perfect maturation of the bulbs, he can with justifiable pride point to results and say—here are the proofs of the fitness of the course I adopt. I may say, that when the bulb-room is closed it is nearly dark; also that there is a space of 6 inches clear between a tray of bulbs and the one above it. *R. Dean, Ealing, W.*

REDUCING THE HEIGHT OF TALL TREE FERNS.—To those readers of the *Gardener's Chronicle* who have Ferns that have grown too tall, a few notes on the apparent success of the following experiment may be of interest. Our plant, *Cyathea medullaris*, was about 20 feet high to the crown, and it being inconveniently high, we desired to root it off in much the same manner as *Crotoms* and *Dracaenas* are done. A stem 7 feet high was cut round the stem, upon which a box 18 inches deep by 25 inches wide was built and filled with sandy soil. At the same time a notch was made in the stem under the box to induce the formation of roots. As the roots gradually permeated the box, the notch was deepened from time to time, until the stem was sawn through as nearly as possible without the head toppling over. I must not omit to mention that the stem above the box was also mopped and kept moist. The Fern was lashed at the end of January last, and as it has now pushed up eight young fronds for a considerable distance, I think we may assume that it is likely to succeed. *James Baxter, Eddle Grange Gardens, Lyngton.*

DAMAGE FROM HAIL.—I am sending a few *Nectarine* fruits to show the damage done by hail on Sunday evening, the 30th ult. The fruits were brought me by Mr. Morris, of Oakwood Gardens, where the trees are fortunately so heavily cropped that when the damaged fruit has been removed there will be sufficient left. The hailstones were unusually large; in fact, a snowball flattened one was measured in my presence, and it was 1½ inch across. The

storm was of short duration and unaccompanied by strong wind, otherwise more serious effects would have resulted. In the Hop gardens many of the points of the bines, 1 and 5 feet high, were cut off, young shoots of fruit trees flattened, and early Pears disfigured. *H. Markham, Maidstone.*

THE FUCHSIA AS A BEDDING-PLANT.—Nothing is more suitable as a bedding-plant than the Fuchsia, whether used as a dot-plant pyramidally trained, or as standards in the geometrical flower-garden, or *en masse* in a detached bed. Several of the species are hardy in the southern and western counties and near the sea-coast, where they frequently escape being cut down for years, and I have seen instances of the wood having assumed the proportions of a tree, but if an unusually severe season occurs, they are killed to the ground. The following eight varieties are worthy of cultivation, and more or less hardy, *F. coccinea*, *gracilis*, *Riccartoni*, *Portmei*, *Sieboldi*, *globosa*, *corallina*, and *discolor*. Many other varieties, however, may be depended upon to make a uniform growth which is most essential when planted in beds. One of the best companions is the one named by Madame Cornillon, a good companion to this being *Lye's Own* or *Mrs. Marshall*. The Fuchsia thrives best on a light open soil, where the wood will ripen early in the season. To insure having good strong hard plants by bedding-out time, the plants should be induced to break into growth early in the season, care being taken that they do not remain in heat a day longer than is necessary to obtain a uniform break; then gradually harden them, and finally place in a sheltered spot in the open air. This applies to old plants which have been kept over from year to year. Cuttings are best struck in the autumn, as when the plants are well rooted, they may be potted into small pots, and kept gently growing on a shelf near the roof-glass in a temperate house all the winter. In February they should be moved into a size-larger pot, giving them a position afterwards in a warm, moist atmosphere, until the roots have permeated the new soil, then gradually harden them off. As a single row or hedge on grass, or as a background to some other object, the Fuchsia is very beautiful; but it is either pyramidal, or as plants with tall stems, that the full beauty of Fuchsia in the open air is best seen. *H. T. M., Stoneleigh.*

FLOWER GARDENING IN THE REGENT'S PARK.—In addition to the spring-flowering bulbous plants Mr. Jordan uses with such fine effects, other subjects of a varied character are employed as carpet plants and various other ways. Carpet plants used in spring beds should flower at the same time as the bulbs, and this characteristic is secured in the useful *Rock Cross*, *Arcia albidia*, which forms dense tufts of foliage and blooms abundantly. The double *Primrose*, *Platypetalus plena*, formed a carpet in one bed, but it seemed to be too near the soil to be effective. *Primula Sieboldi* is largely used as a carpet on some of the raised beds, with groups of *Daffodils* rising up from among it; it is now at its best. When the bloom is over and the foliage begins to turn yellow, the plants are lifted and planted in beds in the nursery, and on the approach of winter a good mulch of manure is applied to the surface. When the creeping rhizomes appear to be becoming active in spring, clumps are lifted and planted out for the spring display. The species, which is the only one at present employed in the Park, is thus wintered in the open without anything like protection. The plants are put out at the end of March. Carnations are very largely employed for the summer display, and they are all raised from layers. Having been wintered in frames, they have recently been planted out in well-prepared raised nursery beds, preparatory to being transplanted for use in the summer effects. A large number is set aside for this purpose, raised considerably above the garden paths, and which has been dug a good deal of road refuse. At the time of planting-out on this border, a mixture of sand, lime, and soot is forked into the surface, and in this the plants do remarkably well. The *Viola* is another subject largely employed by Mr. Jordan in his summer display. Lately he had thousands of rooted cuttings in cold frames, cuttings put into sandy soil in the autumn. The leading varieties are *Bullion*, undoubtedly the earliest *Viola*, with its golden blossoms; *Elizabeth*, an old variety bearing this name; *J. B. Tipping*, Countess *Archie Grant*, *Blue Bell*, &c. Mr. Jordan does not mind some of them being of tall and straggling growth, so long as the colours are suitable, as in association with other plants they take on a kind of

climbing habit of growth, filling out the base of an associated bed, and yet looking freely. A large frame was full of good-sized, shrubby plants of *Hydrangea hortensis*. They are now developing their buds, and are intended for use in some conspicuous position. These are but a few of the leading subjects turned out of this nursery. There is a huge house of very fine specimens of foliage plants, *Palms*, *Tree-Ferns*, &c. *Cannas* in abundance, especially a striking dark-leaved variety; *Marguerites*, *Fuchsias*, *Pelargoniums*, *Nicotiana affinis* in large numbers, *Saxifrages* and *Sedums*, &c., and the charming pyramidal *Celastrus*, which were so striking last year, are being brought in in the form of young plants to take their place in the season's arrangements. *R. D.*

SOCIETIES.

THE AGRICULTURAL SEED TRADE ASSOCIATION.

The members of the above association dined at the Holborn Restaurant on Monday evening, May 31, N. N. SHERWOOD, Esq. in the chair.

The chairman in giving the toast of the evening "The continued success of the Agricultural Seed Trade Association," said that it was founded seventeen years ago, its chief object being to regulate, as far as possible, the dealings on Mark Lane in reference to Clover and other agricultural seeds; and more especially to effect the settlements of disputes that might possibly arise, as it is quite impossible to expect in carrying on such large dealings as are daily conducted, the observance of the strictest moral and legal principles. The object of the association is to settle these by arbitration without the expenses of the law. He thought it spoke well for the working of the association, that year by year disputes were of rarer occurrence, and that those that do occur are settled amicably to all concerned.

Mr. ANTON A. MOSS proposed "The Visitors," coupled with the name of Mr. THOMAS MACKENZIE of New Zealand. Mr. MACKENZIE, in reply, thanked the proposer of the toast, and said that an Association's influence extended a few years ago to New Zealand, it would have saved a trying lawsuit connected with the seed issue in which he was interested, which could have been settled for £300, whereas, by taking it to Court, it cost about £1500. He had been pleased at Mr. LE MAY'S remarks regarding British agriculture, but it appeared to him (Mr. MACKENZIE) that Mr. LE MAY had overlooked one of the most important, namely, the dairy industry, over which this country has so sufficient a strangle hold in this department in New Zealand were astonishing, and their output excellent. England could easily secure that portion of her trade at present absorbed by Denmark. He regretted to see in some spirit of antagonism towards the products of the younger nations of the Empire. At times they were called "foreign," surely it is not so. The strangle hold was "foreign" simply because it was received from a distant part of the same Empire. We were kith and kin, spoke the same language, held true to the same traditions, obeyed the same laws, were loyal to the same old flag. During Queen Victoria's reign the trade of Australia and New Zealand had risen from £100,000 to £10,000,000, in excess of which the total trade of Great Britain and India combined was in 1857.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

JUNE 3.—(Coming so close upon the Royal Botanic Show, the Committee did not expect so many contributions nor any of a very choice character. In this respect, however, they exceeded their expectations, and the members of the committee were no sincere. There has been some remodeling of the Committee; and as now constituted, Mr. THOMPSON, Walton Grange, is Chairman; G. SHORRILL, Bait, Ashford, Vice-Chairman; E. J. DIBBETHAN, Erisdale, Bowdon, Cheshire, Hon. Treasurer; W. A. GENT, Jt., Faulkner Street, Manchester, Hon. Sec., with other 41 members, leaving a vacancy for 5 to complete the full number of 46 for the constitution. The following plants received First-class certificates: *Cattleya Mossii*, *Rapiparrana*, from D. R. RAYNER, noticed elsewhere; *Sobralia macrantha*, from Messrs. F. SANDER & Co., St. Albans, a beautiful white flower of good substance; *Peristeria formosissima*, from Captain S. M. G. RAYNER, with a very fine specimen of pronounced substance, but there is likely to be more of this from recent importation; *Dendrobium Lowei*, from W. G. GILES, Alderly Edge, near Mr. ROBERTS' SHOW, this is the best given piece of this difficult-to-grow subject we have seen, and it well deserves the award, as it is the most vigorous of all the yachess species of the micro-heristic section. He also sent *Miltonia spectabilis radiata*, Grove's variety, which was singularly distinguished. There was some demur as to this award, because the plant from which the spike was taken was not present. It was a very fine specimen, in which the lip is decorated with white blotches and spots, and in the lobes are crowds of small spots. An Award of Merit was made to this grower for a beautifully flowered plant, and extra flowers from *Tendrobium Falconeri*,

as large and as highly coloured as those of *Dendrobium Falconeri giganteum* to which it was compared.

Heavon Lo Co. had an excellent assortment of Cattleyas, the most prominent being one of the Mossie type named Mrs. S. Grating, which received an Award of Merit. It was crowded with flowers, and as a consequence they were not large. The same firm obtained an Award of Merit for C. Mossie Admiral Bradshaw, a flower with a highly ornate lip, but otherwise lacking in quality. C. Mossie E. Ashworth will be elsewhere referred to; it was about the best of Messrs. Low's batch, and received an Award of Merit, as did C. M. magnifica. Goddess (Award of Merit) is a very rich flowering form of the type.

Messrs. F. Sanden & Co. received Awards of Merit for the following plants: *Lelio-Cattleya Fire Queen*, with brilliant lip and fair segments; *Lelio-Cattleya elegans* "Novelty," a pretty form of elegance, with the white blotches on the lobes much emphasised. Like all of the others, it is strong in the segments. We liked *Lelio-Cattleya D. S. Brown* from this firm, which is of beautiful form and substance and highly flamed. *Cypripedium Gertrude Holington* illustre, from Mr. SCHROEDER's collection, received an Award of Merit. It is richer or rather denser in the spotting than the original plant, but not a decided improvement.

Messrs. LINDERS, Peter Leopold, Eberwisch, showed the best grown and flowered lot of Cattleya Mossie in the exhibition. Only one received an Award of Merit, C. Mossie Golith entered as Juno. One named Jubilee passed over by a narrow tie of votes had the largest and best formed lip of any before the Committee, with a broad margin of soft shade of pinkish white. An Award of Merit was voted to a fine and clear form of the *Odontoglossum radiatum* section, a flower as square as those of *O. septrium*, and as spiritising in shades of colours as a *Wilckeum*. It was named *O. radiatum Prince of Wales*. JOHN LEHMANN, Heston Mercury (Mr. Edges, gr.), has an Award of Merit for *Lelia purpurata*. Lehmann, a grand dark lipped form of *purpurata* with better than the ordinary form segments. R. WIGFIELD, Esq., Ashgrove, Sheffield (Mr. Lucas, gr.), had a good *O. crispum* named Stonei.

A Botanical Certificate was awarded to Messrs. F. SANDEN & CO., St. Albans, for the singular and interesting *Dolichopetalum barbigerrum*, a fierce-looking flower seen through a lens.

MANCHESTER ROYAL BOTANIC.

JUNE 24 TO 26. This was held in the gardens of the Manchester Royal Botanic Society, of which we give two illustrations in our present number. It was a much better show than we have seen for some years, particularly as to the number and quality of the Orchids. The miscellaneous exhibits, generally speaking, were fair. It is a favourable omen to see the keenness of competition in the Orchid classes, where competition was wanted, and it is pleasant to note that no one exhibitor, however distinguished his collection may be, can count, year by year, on maintaining a foremost position, which is a happy state of matters. The new Curator, Mr. F. Weatherly, who has youth on his side, is to be congratulated on this first appearance on the stage of entering for a public undeniably fond of flowers and of gardening; but who are somewhat gregarious, and of course follow their leaders in this Whitsun holiday-time to various centres of recreation and amusement. Judging from the spirit manifested at the luncheon by the Chairman, Thomas Statler, of Stand Hall, and his co-directors, there is determination to succeed, and that goes a good way towards commanding success. The weather on the opening day was delightful; the gardens were canopied with trees in their first leafage, and the gay dresses and the music formed a delightful whole.

PLANTS.

The "blue ribband" on this occasion fell to WILLIAM THOMPSON, Esq., Walton Grange, Staffordshire (gr., Mr. C. Brown), who has been the subject of eulogium for a number of plants which came in for much mention from the gardening fraternity. The prime feature in this collection was the *Odontoglossum*, and it is well known what an adept in their cultivation Stevens is. There are "body and sleeves," so to speak in the constitution of the plants, and up to now he has never been fully tried in those species outside of the *O. crispum* section, and in these he takes a lot of beating, although M. Lucien Linden, and other continental cultivators are pushing ahead. Mr. Stevens' most prominent *O. crispum*, was called Thompson—good in form, finely lipped and sparsely spotted on a flushed ground colour. Many choice forms were arching over amidst this forest of floral beauty, and commingled with these was *O. Wilckeum* with a tapering spike of soft lemon and softer chestnut blotches, with just as much of the rugged outline as add distinctness to a beautiful ashy ground colour. *O. luteo-purpureum*, and an exceedingly effective plant of *O. Coradinii* named Rebellini, with chestnut blotches. An effective form of *O. cordatum* was noteworthy; it has yolk-of-egg ground colour, and the blotches are pale brown, standing out in relief among its fellows. There were some good *O. citreum*, which is always a welcome species in a collection; and much branched spikes of *O. Reichschiana*, with its violet blotched flowers standing well alongside of the fine-looking *Lelia purpurata*, which in number and variety formed a beautiful background to this stand. There was one

L. purpurata with 12 flowers with white petals and sepals of unusually good form, with a magnificent flamed lip, of great size and substance, which would have been awarded a prize had it been entered for a special prize—the variety ought to have a distinctive name. The dark forms of this beautiful group, especially *Lelia*, were very striking. The white *Cattleya Skinneri* bore a score or so of such flowers. There were few good specimens of *Cattleya Mendill*, only one first-rate one here. We must not omit a splendid-grown plant of *Odontoglossum maximo majus*, with a score of spikes of insect like white and spotted flowers; and *Odontidium* had a good representative in *Odontidium* with a pyramidal cluster of bright orange small spotted flowers like *Odontidium*, then the charming brilliancy of *Cochlidium Neottiana*, lent colour to the group, with the assistance of a goodly lot of *Masdevallia*, of which *Veitchiana* and *Haryana* are the brightest examples. M. Bull's Blood and regalis were the brightest and best.

The 2nd prize fell to E. A. WORTH, Esq., Hatfield Hall, Wilmsholm (gr., Mr. Hollbrook). Cattleyas and *Lolias* were the chief features of this group; and among the best were C. *Schroederiana* alba, Hatfield House var. (First class Certificate), and many others of good quality; a fine assortment of *Lolias*, some of which the pretty distinct C. *luteola* Koehli, and a fine C. *Schilleriana*. *Lolias* in this group were in fine variety, the pale forms with rosy stripes of the Russian-bred contrasting with the varied anthers striped forms, throwing a glow of brilliancy over the group. There were many excellent forms of species not often seen at shows, such as *Lolias* *luteola* and *Lolias* *Goldfingers*, a very pretty *Odontoglossum Halli*, some good *O. crispum*, and a specially good *O. Wilckeum*; an excellent assortment of *Masdevallia*, brilliant in colour in some cases, and grotesque in form and colour in others. Some of the choicest light-coloured forms of *Miltonia veitchiana* were included in this group.

Mr. ASHWORTH took the 1st prize for a group of about fifty varieties of *Cypripedium*, the best among them being C. *saligerianum majus*, C. *Harrisoni superbum*, a very bright flower; C. *Lathamianum*, C. *Clamberianum*, an extra C. *belatulum album*, and a *Uropetalum Schroderi*. He also took the 1st prize for his specimen *Odontidium*, which was *Lolia purpurata* Russelliana, some very fine *Cattleya Mossie*, an extra fine plant of *Masdevallia Haryana*, and some others.

A WAREBUTTS, Esq., Vine House, Haslingden (gr., T. Lofthouse), had also an excellent lot of plants, and he came in 2nd. They consisted chiefly of Cattleyas and *Lolias*. The choicest plant was *Lelio-Cattleya Lelanthe*, the lip partaking of, but wider than that of *L. C. extensis*; a plant of C. Mossie Jubilee was fine. There were some good light and dark *Lolia purpurata*. THOS. STATLER, Esq., Stand Hill (gr., Mr. Johnson), had the 1st prize for the collection of *Lolias* and *Cattleyas*, Mr. J. C. Brown, of the same firm, and the Hall collection, which is rich in *Lelia purpurata*. Especially noteworthy was *L. p. Statoriana*; and C. *Reineckiana* was one of the best, if not the best forms shown, and C. *Mendill* was large and had a very fine lip.

TRADE EXHIBITS.

Mr. JAMES CUTLER, Cheltenham, had a splendid group at the top of the exhibition house, built out with much good taste. He formed a background to his group with specimen plants in flower, the foreground consisting of Orchids. He was strong in fine varieties of *Lolia purpurata*, and one named Meteor, with highly flamed segments, and a fiery torch lip, was greatly admired. The award of merit also went to Messrs. SANDEN & CO., St. Albans, had a grand group of *Cattleya Mossie* here as usual was strongly in evidence, the points of difference between them being mainly in the form and colouring of the lip. *Oncidium concolor* and *Dendrobium Benseae* are the striking plants in flower.

Mr. J. ROBERTS, Bowdon, took 2nd prize with generally choice plants of *Cattleyas* and *Lolias* being the chief ornament of the exhibit. There was a very superior variety of *Lolia tenax* in flower, excelling in every point; also a spotted variety of *Odontoglossum crispum*. We are afraid the buyers are ignoring these beautiful self forms—there is no more conspicuous than *Odontoglossum crispum*.

Messrs. SANDEN & CO., St. Albans, had a grand group of plants which a large Gold Medal was the award. Chief among them were *Lelio-Cattleya Ayleigi*, singular form, with sepals and petals in the manner of C. Mossie *Haryana*; *Lelio-Cattleya Fire Queen*, described in our notice of Manchester and North of England exhibits. *Cypripedium* × *E. Holti* *Curtisii* × *prestonii*, a distinct looking flower, *Cattleya Mossie Prince of Wales*. *Cattleya O'Brieniana*, a pretty dwarf species with rosy segments and the lip partitioned with white. *Lelio-Cattleya* × *Queen Empress* (First class Certificate), this is one of the best plants on exhibit; it was said to be a cross between C. *Mendill* and *Cattleya Skinneri* (Phloxes, where are we coming to). It is a very distinguished-looking flower, of great substance, great breadth of petals and a champion lip. It is a little flushed in the segments, but notwithstanding the beautiful heavily laden crimson-purple in the lip makes white segments all but unobscured. The award of the judges in respect of choice subjects will be found elsewhere.

Messrs. HEAVEN LOW & CO., Clapton, London, N., had a grand lot of plants. Cattleyas in particular—C. Mossie magnifica, C. M. Mrs. S. Grating, C. M. E. Ashworth, which has the metallic lustre in the lip after the way of *Raportium*. *Cypripedium douglasianum*, a good many double crosses; and again *Cypripedium Curtisii*, bristling with beautiful formed flowers, and *Dendrobium Benseae* in fine cultivation. This collection also received the Society's Large Gold Medal.

Messrs. CHARLES WORTH & CO., Bradford and Heston, who were awarded a Large Gold Medal for their exhibit, had *Lelia purpurata* *Buckhosianna*, with highly-flamed blotched segments with a well-formed lip; *Lelio-Cattleya* and *Lady Wigton*, a beautiful cross, but flowers small here; among many were fine samples of *Cypripedium Goweriana* magnificent splendid flower, of *Odontidium varicosum*, made an invaluable parent. In this stand was also *Lelio-Cattleya Lelanthe*, with four fine flowers shown by Mrs. BRIGGS, Bury Bank House, Accrington (gr., Mr. J. Wilkinson); it has flushed petals, grand oblong lip of abnormal size, bright orange in height, with white, yellow blotches on the convolute limb and bright purple lines running up to base of column.

Messrs. B. S. WILLIAMS & SON, Holloway, London, N., had a Gold Medal for a very good exhibit. Among others not named there were *Oncidium Marshallianum*, *Sobralia nectarina*, *Odontoglossum ornatum*, *Lechmanni*, *Cypripedium benseae*, &c. Messrs. JOHN COWAN & CO., Garston, had an effective exhibit of showy *Lolias* and *Cattleyas*, a very good *Cypripedium Masterianum*, &c. (Gold Medal). Messrs. LEWIS & CO. had in addition to the stock trade of Cattleyas, &c., *Odontoglossum Andersonianum* with bright and distinct spots, *Oncidium varicosum*, the pretty *Cypripedium Stonei*, C. × *concolor* × *villosum*, a grand form of *Cattleya Haryana* *Lewisii*, &c. (Small Gold Medal) Mr. A. J. KEELING, Bradford, put up a choice, if small, lot of Orchids.

Mr. MEASURES, Esq., Canthwell (gr., Mr. Chapman), put up a nice group of choice *Cypripeds*. The following received First class Certificates: C. × *leucobium*, white ground with Indian red spots densely set, with a pouch like *niveum*, one of the *bellatulum* crosses. There was also a nice cross bearing Mr. Chapman's name between *bellatulum* and *C. C. × Rhebania* × *barbatum* and *Godfingers* is a fine bell flower, and it was pleasing to see a note of the *bellatulum* beaten track, whose seedlings are getting too similar.

JAS. BACKHOUSE & SON, York, had a Large Gold Medal for a variety of exhibits staged in the Annex. They had a choice lot of plants for collection, including *Lechmanni*, *Trichomanes*, which were varied with flowering Orchids. The *Sobralia Amesiana* is a striking full flower, combining soft tints of pink and like. In addition there were some charming *Sarcocolla*. The charm of the group was in its setting, as the little gem enclosed in the *Lechmanni* vase. Especially good models for lustre, and the *Arneria Lauchiana*, the pretty *Erinus alpinus*, and the red-flowered Mountain *Anthyllis*, *Meconopsis aculeata*, with its lavender flowers and yellow stamens, were all very attractive.

NOTES.

There was a stiff competition for the group of plants arranged for effect between A. & J. BAKER, Chelmsford, and R. F. KEN & SON, Liverpool, who were the victors. The first group made a very nice arrangement. The material is similar year after year—*Crotoms* and plants with coloured leaves mingled with a few suitable kinds of flowering plants. I liked the number's group shown by Mr. WILKS, gr. to Miss LOAN, Ashton-on-Mersey. It was an *admirabile* properly, and the material used was of the most conspicuous character, remaining one of being in a nondescript meadow, the Grasses, and the Spiraeas, and the Lilies, and a few bright-coloured indigenous flowers calling for general notice.

Messrs. DICKSONS, Chester, had a fine display of flowers of high cultivation, prominent among them being *Lechmanni*, which were Iris *Stansbury*, the *Pyrothrum*, *Poppies*, *Dianthus*, and *Sparaxis*, the last-named giving great variety of form and colour. Messrs. BARN & SONS had a prominent collection of bulbiferous plants. A first class certificate was voted to *Arneria* Mrs. H. Darwin. *Papaver rufiflorum* is a beautiful bluish-tinged orange, and his grand Oriental *Poppies* is such a brilliant scarlet, with the disc and corona as black as blacking itself.

Messrs. HEAVEN LOW & CO., Clapton, had a fine and varied collection of *Cannas*. Messrs. JOHN LATO & SON, Forest Hill, had a grand collection of *Cadidiums*, which are now in the best of colour, and are of the most magnificent proportions even flowers themselves. A First class Certificate was given to "Garden Director," more conspicuous for its ugliness than anything else. *Tuberous Begonias* were well shown and some awards were made. *Cecid Rhoeo* is a good high-coloured double, and a *Lady Penzance* of the Admiral Rawson, which also received a 1st, is a bold scarlet single.

Messrs. RICHARD SMITH & CO., Worcester, had a well-flowered lot of *Clematis*, the semi-double whites being very striking. As specimen plants, formal as they are, they are an acquisition in the make-up of summer shows. W. & J. BURNETT, Sale, had a fine dozen of beauty *Ferns*—pity there are not more of these lovely subjects of Nature got in our midst. Messrs. PAUL & SONS had a good lot of pot roses. Turner's *Crimson Rambler* holds its own, being a popular *Lilies* flower for cutting. Another one named *Paul's Carmine* is a beautiful flamed scarlet single, not likely to last long in flower, but well worth a set of glasses another comes. They had also a nice little lot of *Cannas*.

Messrs. CURTIS & SONS had a fine lot of *Carmations* in pots, which attracted general attention. Germanias is still to the fore as one of the best of the primrose-coloured ones, and for a fine orange variety, a new one named *Andrew Noble* is sure to become popular.

SPECIMEN PLANTS.

MISS LOAN, Ashton-on-Mersey (gr., Mr. Wilks), took first position in specimen plants. Mr. FERRARS, Bolton, had the best *Calceolarias*; Mr. WOODROW, Broughton Park, the best *Gloxinias*, and Mr. JAMES BROWN, Heston-Mersey, the best *Pansies*, as well as some very good pot roses.

FIG. 145.—A VIEW IN THE MANCHESTER ROYAL BOTANIC GARDEN. (SEE P. 390.)

FIG. 146.—"MASSENE" IN THE MANCHESTER ROYAL BOTANIC GARDEN. (SEE P. 390.)

MISCELLANEOUS.

Messrs. W. EDWARDS & SON, Sherwood, Nottingham, exhibited, in ornamental pots, a number of plants suitable for parlor-decoration.

Messrs. JOHN WATERER & SONS had a splendid collection of Rhododendrons in flower, for which they received the large Gold Medal.

THE WEATHER.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

Table with columns for DURATION, TEMPERATURE (ACCUMULATED), RAINFALL, and BRIEST SUN. Rows show data for various days from 0 to 21.

The districts indicated by number in the first column are the following:—

- 0, Scotland, N. Principal Wheat-producing Districts; 1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. Principal Grain-growing Districts; 6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; *Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending June 5, is furnished from the Meteorological Office:—

"The weather was rather unsettled and rainy, with occasional thunder and lightning, during the earlier part of the week, but later on the conditions became dry and fair very generally.

"The temperature was above the mean, the excess varying from 1° in England, N.E. and Ireland, S., to 2° in most other districts, and to 4° in England, E. and S." The highest of the maxima were recorded during the latter part of the period, and ranged from 51° in Scotland, E., and 78° in the Midland Counties and England, S.W., to 73° in Scotland, N., and England, N.E. The lowest of the minima, which were recorded on rather irregular dates, ranged from 37° in Scotland, E., to 46° in England, N., and to 50° in the Channel Islands.

"The rainfall exceeded the mean in England, S. and N.W., the Midland Counties, and the Channel Islands, and just equalled it over Ireland and in Scotland, W., in the other districts there was a deficit, that in Scotland, N., being very marked.

"The bright sunshine was less than the normal in most districts, but exceeded it in Ireland, in Scotland, N., and England, S.W. The percentage of the possible duration ranged from 55 in the Channel Islands, and 57 in England, S.W., to 32 in England, E., and 28 in England, N.E."

ENQUIRY.

THE PAMIAS LILY OF THE VALLEY, WITHANIA ORIGINANDUS.—Will some reader who knows the plant, kindly contribute some information concerning it. X.

Obituary.

JOHN SAUL.—Mr. John Saul, the veteran florist of Washington, D.C., died on Tuesday, May 11, at the age of 77 years. Mr. Saul was born in Lismore County, Ireland, December 25, 1819, and was educated in the art of landscape gardening. When he reached his majority, Mr. Saul went to the Isle of Wight, and a few years later to Bristol, England, managing large nurseries in both places. In May, 1851, he came to Washington. Shortly after his arrival he was employed by the Government to lay out Smithsonian and Lafayette Parks, and several other public squares in the city. He was also engaged by the late W. W. Corcoran to beautify Harewood Park. A year after his arrival here Mr. Saul bought the site on which he built the house in which he died. His business as florist and nurseryman acquired a national reputation. He was particularly fond of rare and odd plants, and what could not be found elsewhere could generally be obtained from him.

He was a member of the Society of American Florists, the American Pomological Society, and many other organizations. His first appointment as Parking Commissioner was received from Governor Shepherd, and Mr. Saul was continued in office after the change in form of the district government by each succeeding Board of Commissioners. He was chairman of the District Parking Commission at the time of his death.

ARISTAKES AZARIAN EFFENDI.—With great regret we chronicle the death of His Excellency Aristakes Azarian Effendi, which occurred suddenly on the 18th ult., on board ship as he was proceeding from Alexandria to Trieste. The deceased gentleman was an enthusiastic botanist and cultivator of tropical fruit-trees, many rare specimens having been successfully fruited in his extensive hothouses. Among others being Annona squamea A. Cherimolia, A. C. Loxensia, A. muricata, Averrhoa carambola, A. Bilimbi, Carissa grandiflora, Carica papaya, C. cundinamaricensis, Coccia punctata, Chrysophyllum lincifolium, Jambosa vulgaris, J. aquea, J. malacensis, Physalis adulus, Persea gratissima, Nephelium longanum, various kinds of Musas and Citrus, Stauntonia latifolia, S. hexaphylla, Spondias tuberosa, Vanilla planifolia, Eriobotrya japonica (vars. off.), and Kakis (Japanese). The decease of His Excellency is the more to be regretted, as his was the only establishment of the kind in Turkey. His remains will be brought to Bagoukdiri for interment. J. Dekkers, Constantinople.

FUNGUS ON BRIARS: N. H., Muswell Hill. The fungus is the first stage of Phragmidium subserotium. Cut away badly-diseased branches, as the later stages of the fungus rest on the branches during the winter, and infect young shoots next spring. Spray with solution of half an ounce of sulphate of potassium in one gallon of water to arrest spread of fungus now. G. M.

GRAPE: J. C. They are affected with "spot," Gloeosporium lotiorum, frequently figured and described in these columns.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—S. M., Perth. Cattleya Mossie. —P. M., Antherston, Hilsstrum.—O. H., 1, a variety of the Wych Elm (Ulmus montana); 2, Hemerocallis flava; 3, Allium moly; 4, Mertensia sibirica; 5, Asperula odorata.—Curatation. Prunus Padus, the Bird-Cherry.—J. W., 1, Leucothoe Catesbeii alias spinosa; 2, Gaultheria Shallon; 3, Pulmonaria officinalis; 4, Lamiium, sp; 5, Pyrus intermedia.—Foreman. 1, Spiraea filipendula; 2, Centaurea montana; 3, Asperula odorata, Woodruff; 4, Polemonium aceruleum, white variety; 5, Polemonium coruleum, Jacob's Ladder; 6, Geranium sanguineum.—Ireland. 1, Honobaria Richardsonii; 2, Escallonia macrantha; 3, Heperis matronalis; 4, Weigela rosea; 5, Veronica spicata; 6, Geranium sibiricum; 7, Hemerocallis flava.—G. G. Thuya orientalis var. filifera.—H. O., A variety of Pavia rubicunda. Send the varieties of Acer palmatum, &c. to some grower of these plants.—Gardener. 1 and 2, varieties of Laila purpurata; 3, Odontoglossum crispum; Odontoglossum cirrosium; 5, Polypodium ligoum.—H. M., 1, Statice Holdfordii; 2, Cratogeomys pyracanthus; 3, Begonia Digwelliana; 4, Pteris Victoria; 5, Ardisia crenulata; 6, Fieris argyræa; 7, Lactuca tenacitallis; 8, Cypripedium longum.—G. H. The Cypripedium is probably one of the numerous forms of C. x Ashburnton. The Cattleya Warscewiczii, with fine flowers, is a grand example.

SEEDS: C. C. W. Estada scandens, West Indies; probably drifted over the Atlantic Ocean.—H. S. We do not recognise the seeds.

THUIAS: Winchester Correspondent. It is a common thing for these plants to lose their lower leaves and branches in the nursery lines, and after they are permanently planted.

TWO PERFECT FRUITS OF THE PINE-APPLE ON ONE STALK: J. L. Such an occurrence is rare in plants under cultivation.

VINES FIVE YEARS PLANTED, AND EIGHTEEN FUNGUS 3 TOMES EACH PER VINE.—J. B. C. A crop of 3 cwt. of fruit from each vine of this age is too great a weight, and will be followed, probably, by weakness, that will result in shaking, loss of colour in the fruit, &c. We noticed only one really shakled berry, but the beginning of rust on several among these set.

VINES: E. H. B. The Vine is attacked by the fungus Sclerotinia Fuckeliana. An account of this fungus, along with preventive methods, is given in Gardeners' Chronicle, May 15, 1897, under heading "Vines" on p. 328.

COMMUNICATIONS RECEIVED.—W. E. B., Grahamb—Sir C. S.—R. H. B.—Carte—C. H. D.—Chas. W. Simmons.—A. C. ACER LEOPOLDI: J. W. We assume that the raiser of this variety of Acer Paucot-platanus gained it in honour of the King of the Belgians.

BOOKS: J. T. R. One of the best is The Orchard Growers' Manual, edited and published by Messrs. B. S. Williams & Son, Paradise and Victoria Nurseries, Upper Holloway, N.

CARNATIONS: Corfe Muller. (1.) The flower of the old pale bush or white-flowering Souvenir de la Malmaison variety is average in size, and not remarkable. (2.) The rose-coloured one is similar to some of the varieties now in commerce, but the bloom sent is undersized. (3.) Blooms measuring 7 inches across and 4 inches deep would certainly be exceptional—indeed, unique. (4.) It is not general, in the case of good growers, to allow their plants, even when three years old, to grow to a height of more than 4 feet. They very properly seek to obtain a large bushy plant with numerous growths. (5.) Yes, there are already some striped varieties of Souvenir de la Malmaison in nurserymen's lists—Sir Evelyn Wood, to wit, which has a pale pink ground colour, striped with much darker shade.

CYCAS CRINALIS FRUITING: J. Cocker. Net uncommon; the seeds will not be fertile unless you have the male plant also.

(Matters carried over to p. xi.)

THE

Gardeners' Chronicle.

SATURDAY, JUNE 19, 1897.

WINDSOR.

IN our issue for October 31, 1874, we published, in the form of a fully-illustrated supplement, a pretty full account of the Royal Parks and Gardens at Windsor; and much of what was then published is applicable to the present condition of the royal demesne, so comparatively slight have been the changes which time has wrought in the interval. We may repeat here the opening paragraph of the account then given:—"If, in the matter of royal palaces in general, we have not much to boast of, we have one which, in beauty of position, dignity of aspect, appropriateness of surroundings, and fulness of associations, extorts from no reluctant lips the opinion that Windsor is a residence worthy the Sovereign of so great a nation,

"Worthy the owner, and the owner it."

Like all our great institutions—like human life itself—the history of Windsor presents great contrasts; now a palace, and now a prison—at one time the place where the Norman monarchs kept their Whitsun and Christmas-tides, where in the first three Edward's days great tournaments and revels were held, where Elizabeth kept festival, where Henry VIII., Charles II., James II., Dutch William, Anne, the Georges, and especially George III., passed much of their time, and where, in our own time, much that will be historic has taken place. On the other hand, it has its gloomy memories: here prisoners were "miserably furnished to death;" here John was almost, if not quite, a prisoner till he signed Magna Charta at Runnymede hard by. The French King John, about a century and a half later, was a prisoner here after the fortune of war at Poitiers had led him to surrender to the Black Prince and his father, the third Edward. Here the unhappy James I. of Scotland was imprisoned early in the fifteenth century. Here two centuries later Charles I., another of the same ill-fated family, was for a time imprisoned, and in 1648 passed his last Christmas; and here another woeful Christmas-tide, within our own times, was marked by a Queen's anguish and a nation's sorrow.

THE TERRACE GARDEN.

This consists of a parterre of three to four acres in extent, and constructed in 1824. It is 12 to 15 feet below the level of the terrace, and is partly enclosed by an orangery, now chiefly

devoted to the storing of tender bedding plants in the winter, and where they succeed without any artificial heat being employed. The flat roof of this house forms part of a walk. A feature of this garden consists of pyramidal evergreen shrubs, chiefly Hollies in variety, Golden Thuias, which range in height from 3 to 10 feet, and form a background and foil to the gay occupants of the beds. Both spring and summer bedding are carried out, and for the latter about 50,000 Pelargoniums in variety are employed, besides large numbers of other plants.

The view from the terrace in all directions is very beautiful. In connection with the castle it may here be mentioned on the authority of Messrs. Tighe & Davis, that as late as the reign of George III. a small vineyard existed on the outside of the south wall of the lower ward of the castle. The ground slopes from the castle-walls on one side down to the Thames, and on the other towards the Home Park. Hereabouts are the slopes, abundantly wooded, and abounding with wild plants and ordinary kinds of shrubs, Portugal Laurel, Bex, and exhibiting but little ornate planting of exotics, and with deliciously restful for its freedom from garish colours. The trees consist of Oak and other indigenous species, the Gean, or wild Cherry, attaining to a large size.

At the top of the slopes, and adjacent to the castle-wall, is a fair specimen of the Cedar of Lebanon, planted by the Prince Consort a day or two after his marriage. The Queen's favourite collie lies buried beneath the shade of its branches; and close by may be seen a fine Paulownia in full bloom, and one of the largest specimens of *Köhleria paniculata* in the country, which in spring offers a sheet of golden yellow colour.

At a point just below the terrace, and on each side of the road leading to it, an avenue of jubilee trees, fifty in number, will commence. These trees will consist of specimens of *Cobus atlantica glauca*, prepared for the purpose by Messrs. Veitch & Sons.

Some distance down the slope is a rockery with a cascade, well adapted for the cultivation of the choicest Alpines, but which now contains few rare plants. An elegant, and apparently now seldom used summer-house stands hereabouts; and from a pebble-lined grotto situated on the upper side of the rockery a good view of the latter is obtained. A sharp descent led us from the slopes to the level of the park, noting on the way a stately Oak girthing some 36 feet at 4 feet from the ground, a noble Elm of first magnitude, and the substitute for Heine's Oak deceased; and a short drive over well-kept gravel roads brought us to the orchards and gardens of—

FROGMORE.

The old orchard consists of trees planted

probably about 1824, and consequently they are not very productive, and of young ones planted between them by Mr. Owen Thomas, the present head gardener. The new orchard, planted in November, 1892, consists of 100 standard trees, standing at 24 feet by 15 feet apart, the culinary being two-thirds, and dessert varieties one-third of the total number. All of these young trees, having been planted with the utmost care, are making good, but not excessive growth, and they will, in the course of a few years, come into bearing. In the neighbourhood of the orchards there are some fine trees of *Sequoia (Wellingtonia) gigantea*, a species which makes strong, healthy growth on the stiff soil. Most of those observed are either grafts or cuttings taken from the fine specimen which forms a prominent object in the park near to the castle.

THE FORCING-HOUSES.

These are somewhat old-fashioned, roomy structures, arranged in groups and ranges, and well adapted generally to the uses to which they are put.

It is worth noting the manner in which the ground on the south side of the ranges of glass-houses, wherever it could be conveniently done, is sown with Chelsea Gean or other early variety of Peas, and how extremely prolific of pods the plants are in these positions.

The first viney we entered contained Black Hamburgh Vines, carrying a regular crop of even-sized bunches, fit for consumption during the present week. The berries were of average size, of capital colour, and the bunches compact. Another viney, which is 40 feet in length, was filled with the canes of one Vine only—a Foster's Seedling, the stem of which passes along the back wall near the top, and sends down rods to the front of the viney. The crop here was a good one, and the bunches excellent in size and appearance. Close by is a viney from which fruit is being cut for the royal table; the bunches were of serviceable size. A viney was visited in which a row of young Vines are growing in a high brick bed constructed in the middle of the house, these Vines being intended for fruiting early in 1898; other Vines being planted in the front of the house to form the permanent occupants, and whose rods are in the outside and inside borders. Both lots of Vines are doing well. Excellent Madresfield Court and Duke of Buccleuch Grapes will likewise be fit for the table in the present week. The Vines which will furnish the fruit occupy a viney to themselves.

A Muscat viney of old-fashioned construction, as was shown by the front lights of 7 feet in height, contained a well-cropped lot of Vines in perfect health. There are several late

vinceries of great dimensions, in which the bunches were being thinned, and the crops seemed to be more than ordinarily heavy.

As may be imagined, houses for the cultivation of the Peach and Nectarine are many, and the trees in some of them were already denuded of their crops. What is called the second house contained four large fan-trained Elrage Nectarines and three Bellegarde-Peaches; and doubtless there are other houses in which are to be found successional trees, both Nectarines and Peaches.

Musa Cavendishi is regularly forced for the production of fruit, a house being set apart for its cultivation. Two lines of plants occupied a bed in the middle of the house, stocky, vigorous examples; and it is Mr. Thomas' practice to take a bunch of fruit from the parent-plant, and another from a selected number of the first crop of suckers. The bed is then cleared wholly or in part, and replanted.

Of Melon-houses there are several, and it was remarked that the variety Frogmore Orange, and a seedling not yet rejoicing in a name, are the favourites this year. Behind one of these Melon-houses we found a house filled with a useful lot of Ferns.

As is well known, the cultivation of the Pine-apple has never declined at the Royal Gardens, and the fruits obtained now are as good as they have always been.

We were allowed to peep into a pit filled with examples of "The Queen" rapidly approaching ripeness. There were other pits filled with fine plants of Royal Sovereign Strawberry, which will continue to give ripe fruits throughout the present month. It was remarked that that old variety of French Bean, Osborne's Forcing, is the one grown under glass, it being an excellent producer of low stature.

THE PALM-HOUSE.

The Palm-house—the subject of the supplementary illustration (fig. 154)—is one into which a carriage and pair can be easily driven, and in which, in point of fact, Mr. Thomas has the vans brought for the purpose of loading them with plants for the decoration of the castle when outside conditions are unfavourable. Musa paradisiaca, which fruits well, and is much liked at the castle, fills the beds at the sides of the stone paths, and Dracenas, Pandanus, and Caladiums, fill the intervening spaces, whilst Selaginella denticulata forms an agreeable border to the beds.

THE CONSERVATORY.

or flower-house, is a building of considerable length, with high side-lights, furnished with a wide bed in the centre, in which are large plants of the Canellia, and with a narrow bench on the sunny side. Among creeping plants for adorning pillars and wall-spaces *Cobcea scandens variegata* is commonly employed, and we noted also the old-fashioned pretty *Rhodochiton volubile*. The bench was gay with Pelargoniums of the French spotted type, zonals, *Schizanthus* in variety, Hydrangeas, *Primula japonica*, Ericas, and a number of seedling varieties of *Cineraria cruenta* which had an uncommonly gay appearance, and were as genuinely pleasing to behold as the more brilliant and large-flowered florist's strain.

From the conservatory the visitor enters the Orchid-house, which is not, however, entirely given up to Orchids, as besides *Cypripediums*, of which *Lawrenceanum*, and var. *nixium*, and *Laelia purpurata* in many examples, were in bloom, there were numerous plants of *Anthurium Schzerianum* with spathes, bright-looking *Caladiums*, Tuberoses in flower, and a

miscellaneous collection of *Cattleyas* and *Laelias*, &c., whose flowering was past. The Cape *Pelargonium* in show, decorative, and spotted varieties, receive much attention, these plants being extremely useful in indoors decoration, of which there is an enormous amount to be done at times. Of the decorative type, a variety named *La Volupté*, a semi-double pure white flower, was much in evidence, as were likewise in the same span-roofed house *Lilium longiflorum* variety, and the white-flowered *Hydrangea* Dr. Hogg.

Another house was filled with *Caladiums* of a useful size, with plants of *Gardenia floribunda* filling a bench at the back of the house. Plants of *Bougainvillea speciosa* and *Stephanotis* partially clothed the roof and the back wall. In

one, and were slightly shaded overhead by the growths of *Niphetos* and *Celine Forestier* Roses. The beautiful *Cassia corymbosa* loaded with its orange-coloured sprays of flowers, and a plant of *Bougainvillea*, occupied places on the back wall. Numerous plants of *Clivia miniata* in variety were making growth here.

KITCHEN GARDENS.

This most important adjunct to the royal residence covers in all about 50 acres, a large portion being enclosed within walls 12 feet high. Having so large an area to deal with, the gardener finds the plough and harrow and the horse-hoe more economical implements than the spade, rake, and hand-hoe to employ in breaking up and tilling the land.

FIG. 147.—KEW PALACE, IN THE ROYAL GARDENS, KEW.
(Photograph for the *Gardeners' Chronicle* by J. Gregory. See p. 395.)

a stove we came across an enormous plant of the Dove Orchid, *Peristeria alata*, the butts of whose flower-stems measured three-quarters of an inch in diameter, a good indication of what their strength had been. Some choice species of Palms were found here, namely, *Licuala grandis*, a *Demonorops*, some capital *Marantas*, *Dieffenbachia Bausei*, several *Nepenthes* with pitchers, viz., *Curtisi*, *mixta*, *Dicksoniana*, *Ameisiana*, *Hookeriiana*, *Mastersiana*, &c.

Besides these fine subjects there was the usual assortment of tropical foliage plants. The new popular *Canna* occupied a small house, and was represented by a number of the newer continental varieties.

The collection of foliage plants overflows into still another house, and here were the *Colladiums* (*Crotons*), *Pandanus*, *Dracenas*, *Acalyphas*, *Xyris*, and other showy plants. Examples of *Lilium speciosum* were being forced into bloom in a house adjoining the last

The various successional sowings and plantings are upon a colossal scale, the requirements of several Royal palaces having to be furnished from the Frogmore Gardens.

Every kind of crop had a thrifty look, betokening careful culture; and cleanliness prevailed in every part of the gardens.

The fruit-trees on the walls are very numerous, Cherries, Plums and Pears predominating; and almost every kind of fruit has to conform to the fan-system of training, which is carried out most carefully and accurately. Few old trees were observed on the walls, these being removed on the first signs of decline of vigour.

In spite of the complaints from all parts of the country of the total or partial loss of the fruit crop, and of damage done to early Potatoes, &c., there was not much evidence that any considerable injury had been experienced at Frogmore—on the contrary, the look of the

Potatos left nothing to be desired; and the crops of Strawberries, Cherries, Pears and Plums, were generally satisfactory. The gardens are in excellent keeping, and Mr. Thomas, to whom we are under great obligations, is evidently the right man in the right place.

KEW PALACE.

TO the right of the main walk, going towards the Palm-house from the entrance, is the pictorial red-brick Jacobean mansion known as Kew Palace (fig. 147, p. 394). Its history, so far as it is known, is summarised by Mr. W. T. Thiselton Dyer, the present Director, in the *Kew Bulletin*, No. 60, December, 1891. It is said to have been leased to Queen Caroline in the reign of

KENSINGTON PALACE.

WITH rows of straight windows and severe architectural lines, this is a characteristically Dutch building (fig. 148). It is at the western end of Kensington Gardens. In this palace, on May 24, 1819, Her Majesty was born, and here she passed much of her childhood, tending the flowers in the garden as we are told, a circumstance that would seem to indicate a much smaller and less intrusive a population than the present. For a short time the Duke of Kent rented a mansion at Ealing, and loyal residents of that suburb have designated one of the roads as "Queen's walk;" but, if the records are true, the Queen's walking must have been effected vicariously in the arms of her nurse, for the Duke died when his child

bedding plants, and other decorative plants used for the embellishment of the park. Three large span-roofed houses contain a selection of fine plants of Palms, Tree-Ferns, *Musa Ensete*, and similar plants, which will soon be placed in position. A few fine standard Bays in tubs are here harmonising with the architectural features of the palace, and with a large red-bricked orangery used to shelter Agaves and other plants. The view from the front of the palace, looking eastward, is just now, considering its situation, magnificent. Noble avenues of verdure radiate in different directions from the Round Pond, and now that the trees are in full foliage, you may look and look again, and not see a house. Close by is the Flower Walk, where John Leech represented a youngster innocently asking, with reference

FIG. 148.—A VIEW OF KENSINGTON PALACE, THE BIRTHPLACE OF QUEEN VICTORIA, AND HER RESIDENCE TILL HER ACCESSION.

(Photographed by Messrs. Stiles, Kensington.)

George II., and subsequently the freehold was purchased by, or for, Queen Charlotte. George IV. was educated here, under the superintendence of Dr. Markham, afterwards Archbishop of York; and the Royal Family resided here till the death of George III. in 1820. Its connection with this present year of rejoicing lies in the fact that the marriage of the Duke of Kent to Princess Victoria of Saxo-Coburg took place in Queen Charlotte's drawing-room on July 11, 1805. The Duke and Duchess after the wedding proceeded to Claremont. The Duke of Clarence, afterwards William IV., was also married here; and Queen Charlotte herself died here on November 17 of the same year.

At present the Palace is untenanted, though there are many purposes to which it might advantageously be applied. In any case, it forms a very pictorial adjunct to the Royal Gardens.

was less than a year old, so that the education of the Princess was carried on under the supervision of the Duchess of Kent, the sister of Leopold, the first King of the Belgians. At Kensington Palace early one summer morning, as every one has been told, the Princess was made aware of her accession to the throne. What she said, and what she did, is it not recorded in every newspaper in the land!

Gardening is carried out only on a small scale in the vicinity of the palace, ordinary lawns, shrubberies, and flower-beds encircling the building. But here is placed a statue of Her Majesty, executed by H.R.H. the Marchioness of Lorne, and placed in its present position "to commemorate fifty years of her reign." The Queen is represented as seated, crowned, and in her robes. Close by the palace are the houses and pits, wherein are grown the

to a small plant of *Koeleria paniculata*, why so small a plant had so long a name! The Flower Walk close by, a favourite resort in times gone by, still retains much of its beauty, though possibly not up to the standard of former times—or is it we that have changed? At any rate, there it is—a delightful bit of gardening as it is, backed up by trees and shrubs, such as weeping Beech, pyramidal Oak, cut-leaved Limes, Lombardy Oaks, and many rarely met with now-a-days, and with bold masses of perennials in front, making a fine display. To give a list of those now in bloom would be to write a catalogue. Let us rather recommend the reader to lose no time in visiting Kensington Gardens before the freshness of the foliage is dimmed, stroll through the flower-walk, and continuing his walk, feast his eyes on the brilliant show of Rhododendrons made by Mr. Anthony Waterer.

BUCKINGHAM PALACE GARDENS.

(BY SPECIAL PERMISSION OF HER MAJESTY.)

NEW Londoners have been privileged to visit these Gardens, unless, it may be, when the Queen receives her visitors on the lawn at a garden-party or other state-function, and few are aware of the scenes of sylvan beauty concealed behind the somewhat gloomy-looking walls. Extending from the garden-front of the Palace on the east to Grosvenor Place on the west, and from Constitution Hill on the north to Buckingham Palace Road on the south, is an enclosure begirt for most of its length by a high brick wall. Raised mounds and groups of trees are disposed along the boundaries, and ensure seclusion from all but the upper stories of a few houses in Grosvenor Place.

The situation is low—its surface is naturally nearly level; the soil clay. Practically it is continuous with St. James' and the Green Parks, whilst the width of the roadway at Hyde Park Corner alone divides it from Hyde Park itself. A more central locality for the residence of the Sovereign could thus hardly have been selected, and one less encumbered by buildings and obtrusive structures. As a royal residence, it does not long antedate the reign of Her Majesty, for the Palace, previously the property of the Duke of Buckingham, was purchased by George III., and remodelled by Nash in 1825, at the command of George IV.

The area uncovered by buildings is about 40 acres, of which the lake comprises 8. The rest is undulating greensward, with groups of trees, shrubberies, and a few flower-beds. So judiciously has the surface been laid out that the boundaries are concealed, and the destination of the paths is not seen till they approach their termination. The space, therefore, seems much larger than it really is. In leafy June the visitor might easily imagine himself in some noble park far removed from the great city, were it not that the low roar of the London streets is continuous day and night. Nothing stops that; whilst, in the winter time, fog and smoke beyond the average invade even the precincts of Royalty, and tax the skill of the gardener even to keep the leaves on his *Pelargoniums*. Some fine Beeches, Elms, Hornbeams, Hollies, Ashes, Turkey Oaks, Copper Beeches constitute the staple of the trees, intermingled with Lilies and Laburnums. Conifers naturally do not thrive in a London atmosphere, but here is an exception in the case of the deciduous Cypress, *Taxodium distichum*, whose feathery foliage gives character to the surrounding vegetation. A small Cedar of Lebanon, too, impresses its distinct outlines to advantage among the billowy heads of the Elms.

Rhododendrons and Azaleas brighten the scene in early summer, and a few flower-beds give colour later on. For bedding purposes, Mr. Stirling, the gardener, depends largely upon *Fuchsias* and bright-hued feathery *Celosias*. *Violas* and Ivy-leaved *Pelargoniums* contribute their share to the adornment of the beds. Many of the glades and shrubberies seem well adapted for the introduction of Irises, *Peonies*, and other herbaceous plants, which do well in the adjacent parks; whilst *Daffodils* and *Blue Bells* might add an additional charm in spring. But we are "reckoning without our host." The lordly peacocks are neither few, nor are they considerate. They claim, or at least they take, equal rights with the gardener. Bare patches on the slopes and on the lawns, and wholesale destruc-

tion even of Ivy, give one an idea of the appetites of these gaily-bedizened fowl, and of the difficulties with which the gardener has to contend. In spite of these veritable mar-plots, the turf is as delightful to the eye as it is restful to the foot; and the sinuous lake, and its branches embowered in trees, constitute a scene of beauty that could hardly have been anticipated in the centre of a mighty city. How gay the scene will be in the forthcoming festivities may be imagined from the accompanying newspaper paragraph:—

"The Queen's Barge-master, and eight Queen's watermen, have received instructions to attend the Jubilee festivities at Buckingham Palace from Sunday the 20th to Monday 28th inst. At the garden party on the latter date, extra watermen and craft will be requisitioned."

One of our photographs (see supplementary illustrations) was taken from the top of a steep mound, which hides out the mews. Its summit is crowned by an elegant pavilion decorated in the interior with frescoed panels by Landseer and other artists. From the terrace in front of this summer-house, we look down upon a point where the lake forks into two divisions. The haze in the background—we fear, dust and smoke in reality—suggests limitless distance, an effect enhanced by the concealment of the boundaries and the graduated outlines and shadows of the trees in the foreground and middle distance. The view suggests, on a small scale, that from the terrace at Richmond.

An architectural conservatory of stone, on the north side of the palace, closely resembles the Aroid-house at Kew, which, indeed, originally occupied a position in these gardens. It is filled with tall Palms, *Kentias*, *Scaevolias*, and the like for decorative purposes; whilst the side-stages, like the pillars supporting the roof, are clothed with zonal *Pelargoniums*, forming a blaze of colour at the time of our visit.

At one corner of the ground is Mr. Stirling's house, and a few span-roofed houses full of small Palms for decorative work, and pits adjoining for the culture of the *Celosias*, *Fuchsias*, and plants used for bedding. Some of the pits contain an excellent collection of *Caladiums*, whilst amongst the *Dracenas* one called Lord Wolseley is found to be specially useful for its powers of endurance. *Azalea amœna* is also grown in some quantities, and is very effective in spring.

One curious circumstance was pointed out to us as we were leaving the ground, and that was that the Ivy refuses to produce clinging roots and to attach itself to the old brick walls without the aid of nails. How this is to be accounted for we do not know, for in other parts of the town with an atmosphere more filled with impurities than it is in Grosvenor Place, we have seen Ivies of many kinds clinging to the old brick walls without artificial aid.

A door in a wall is opened, we heartily thank our conductor, and we pass from the reposeful beauty of the royal pleasure-ground into the hurry and turmoil of a busy London street.

OSBORNE.

VERY different in character to the large and historic establishments of Windsor Castle and Buckingham Palace is the Queen's residence near Cowes. There is here the quiet restfulness that go to make many country residences enjoyable retreats, and it is possible for Her Majesty to dispense with many ceremonies and formalities that attend her life at

either of the other places mentioned. Indeed, the visitor soon feels that Osborne is in many respects what one might expect Her Majesty's private residence to be.

Osborne lying on the northern side of the Island, is very much less favourably situated from a gardener's point of view than Ventnor or Shanklin, which are sheltered from the north by high cliffs.

From East Cowes the distance to the entrance to the Osborne estate is but small, though the good-humoured, importunate drivers of conveyances, when soliciting the patronage of a visitor, never fail to describe it as "at least a mile and a half." There are numerous entrances in this locality, and several of them seem to indicate Royal Osborne. The estate, which includes a model home-farm, stretches many miles, and the distance from Cowes nearly to Ryde may be traversed by the shore without leaving the estate, which contains as many as twenty-five miles of drives and walks, and two thousand acres of land.

The mansion, built after the Italian style, has two towers, and on the south-east side is the lately-added wing, containing the sumptuously-furnished Indian rooms. The ground slopes considerably down to the Solent north of the house; and though the pleasure-grounds and estate are generally well sheltered on other sides, there is much exposure to the bleak sea-winds from the north, which were so cutting at the time of our visit as to cause us surprise that many tender shrubs withstood such exposure so well. The climatal conditions of a garden at Cowes are indeed different to those of another at Ventnor, though but about a dozen miles distant.

The view that may be had from the top of the house, and which stretches over Osborne Bay, is a charming one indeed. Immediately below the house upon this side is a grand terrace, and some smaller ones interesting to the gardener, because the beds contain plants that in the northern parts of this country are known only as greenhouse plants, and upon the walls of the terraces are plants of the same character. Amongst the latter, none is used more commonly and does better than the *Myrtle*, several varieties of which are noticed again and again. *Yuccas* have been planted in numerous cases in miniature beds, and upon the grass, where they grow and flower well. Several other features upon the north side were interesting to us, one of which is a gigantic specimen of the Chinese Palm, *Trachycarpus* (*Chamaecrops*) *Fortunei* (see fig. 156), possessing a clean, handsome stem for upwards of 20 feet, and above this a good foliated top. A special tent is built over this each autumn to protect it from possible injury during winter. Then there are beds of fine *Camellias* here also, which flourish well. The bushes—some of them of large size—had completed their growth, and presented a capital crop of flower-buds. In the case of *Camellias* out-of-doors, though, let the position be as favourable as it may, success depends very much upon the weather during the time the flowers are opening; they are so easily disfigured by damp as well as cold.

Near to the Terrace is a very pleasing arbour, or arcade, covered with *Grape-vines*. Being of good height and proportions, it is much more inviting, especially during bright sunshine, than the somewhat formal arrangements which prevail around it. A part of the flower-garden is illustrated in fig. 149. It is rather formal in style, and during the summer is kept very gay with flowering plants of an ordinary character.

It is on a slope upon the opposite side of the house, and much better sheltered, that the greater number of Coniferous trees, and more or less tender shrubs, have best succeeded. *Escallonia macrantha*, which may be seen in numbers in many parts of the Island, does well here. It is a dark, glossy-leaved shrub, with conspicuous crimson-red flowers. Another shrub well worthy of mention is *Desfontainea spinosa* an evergreen Holly-like Loganiaceous

flower and bear seeds freely. The Tulip-tree (*Liriodendron tulipifera*) grows and flowers well, too; but the specimens of *Pandownia imperialis* are not so good, probably the winds are too keen, for on the southern side of the Island they flourish well. *Embothrium coccineum* is less happy here than it is sometimes seen. It is a small South American evergreen shrub of very ornamental character, and produces showy, pendent, orange-scarlet flowers; it should be

trees of one species or another in conspicuous places throughout the grounds. But this brings us to speak of the—

MEMORIAL TREES.

one of the semi-private features of the pleasure-grounds at Osborne. To write a complete history and description of them would be to write a history of the private life of the Queen during a great part of her long reign. Since the late Prince Consort purchased the estate from Lady

FIG. 149.—A VIEW OF PART OF THE FLOWER-GARDEN AT OSBORNE.

(Photographed by Hughes and Mullins, of Ryde.)

plant from the Andes. The tubular flowers have a scarlet corolla and yellow limb, resembling to some extent those of the better known greenhouse plant, *Libonia floribunda*; it grows and flowers here freely each year. *Buddleia globosa*, as might be expected, is very happy; and apparently so is *Photinia (Eriobotrya) japonica*, the Japanese Medlar or Loquat, an attractive shrub at all seasons of the year, but of too tender a character for any but warm and sheltered situations. There are fine plants of *Fatsia japonica* (the old *Aralia Sieboldii*) in many instances, and they

tried in all situations where it is likely the plant may succeed. *Eucalyptus globulus* is seldom badly injured, and the *Catalpa*, *Quercus glabra* and *Quercus flex*, all figure among the denizens of the pleasure-grounds. The last-named *Quercus* (Evergreen Oak) does uncommonly well, and reminds us of the immense leafy specimens we are familiar with around Cardiff Castle and in other localities in South Wales. A magnificent specimen on the lawn, near the front entrance, is 250 feet in circumference, and is one abundant mass of foliage. The great family of *Conifere* is represented by

Isabella Blachford, and it has been in use as a Royal residence, it would appear that the most distinguished visitors to Osborne have been "tree planters." The rulers of Germany, Russia, and other countries, have all essayed the task, and besides, we noticed a specimen of *Sciadopitys verticillata*, planted by the Queen herself; and an *Abies Pinsapo* which remains as the result of the work of the late Earl of Beaconsfield. In every case the tree has a substantial label affixed to it, denoting by whom and when it was planted. In view, however, of the liability there exists in

the best regulated gardens—even Royal ones—for labels to go astray, we believe a book is kept, in which is a complete record of these particulars. It would be instructive to carefully note the date of planting in individual cases, and the progress the tree has made, but our time did not permit of doing this systematically, though many particulars of this kind are given when speaking of "Queen's Trees" on p. 105. The *Cryptomerias*, *Retinosporas*, *Abies Pinsapo*, *P. pungens*, and the species of *Cedars*, had all made satisfactory growth. There is a magnificent Cedar close to the house, presumably *C. Libani*, of fine proportions, upwards of 50 feet in height, and quite as much in diameter. Then there are other memorial plants of a more private nature than the trees, and they are plants which have been struck from "ships" contained in Royal bouquets. Thus, many of the Myrtles that abound owe their life as well as much of their interest to a wedding, a baptism, a confirmation, or possibly a death in the Royal family. For instance, we were shown one that was struck from a cutting on the occasion of the marriage of our Princess Royal, now ex-Empress Frederick of Germany. Many such cases occur, and to members of Her Majesty's family they must afford unusual interest, especially during this the sixtieth year of Her Majesty's reign.

The Swiss chalet, or cottage as it is called (see fig. 150), contains a museum of natural history, and other curiosities. Besides being interesting in itself, this cottage is surrounded by the flower-beds and small kitchen gardens that used to belong to the young Princes and Princesses many years ago. The little garden-tools are still preserved there, including the wheel-barrow that was once part of the Prince of Wales' equipment, and bears the letters "P. W." upon it. The initials, indeed, of most of the Royal children may still be seen on the handles of one or other of these very interesting relics of the time when the Queen's children were as young as her great grandchildren are now. The grounds around Swiss Cottage also contain many of the memorial trees.

The Hollies in great variety are exceptionally fine, particularly *Ilex pendula*. Some of the specimens of *Cupressus macrocarpa* are now 60 feet to 70 feet in height, and appear to have thrived best among the Conifers that have been planted on the estate.

The kitchen garden is a small one, and not specially remarkable. There are ample means at Windsor for the production of vegetables and fruit, that more at Osborne may not be necessary. It should be mentioned, however, that in one corner of the kitchen garden an Orange-tree grows and fruits well upon a wall; during cold weather in winter it is protected by wooden shutters.

Much conjecture has been written in the press about—

THE GLASS-HOUSES

at Osborne. Sometimes it is said there are few, and at others that there are no fruit-trees. But some time ago a paragraph was circulated containing the news that Her Majesty had decided to build an extensive range of such structures, and that she was about to acquire additional land for the purpose.

If a new winter-garden were thought desirable, an estate of much less extent than Osborne would afford an abundant site. But we were unable to learn of any sufficient ground that existed for the suggestion.

The houses there at present are useful for the production of flowers for cutting, and of de-

corative plants for furnishing the mansion, which, during the time the Court is in residence—as at Christmas—are required in considerable quantities.

Our visit was made at a season when the houses might be expected to look less gay than usual. There were plenty of well-grown bush plants of late-flowering *Chrysanthemums* in bloom, and previously at some of the exhibitions in Hampshire, *Chrysanthemum* blooms from the Osborne collection had been shown successfully in competitive classes. Plants of *Solanum capiscistrum* were likewise good, and much better "berried" than we sometimes see them. Another well-known plant had been cultivated to good advantage in the stove, viz., *Euphorbia Jacquinaeflora*, plants of which had fine long shoots with healthy foliage retained nearly to the base, and numerous opening flowers.

Carnations, especially the winter-flowering sorts, are done well, and the plants were in good health. They are especially convenient and pleasing for the making of bouquets for the Queen, who, in her well-known distaste of artificiality, prefers to have her flowers unwired; and it is said she not uncommonly pulls her bouquets to pieces, and re-arranges the blooms in glasses with her own hands. Violets are cultivated in frames to supply plenty of blooms during Christmas and the succeeding weeks. Occasionally, when large dinner-parties are given, extensive table decorations become necessary. Ordinarily, this work is done by persons who travel with the Queen for that and similar purposes, and known as the "deckers;" but the gardener has to do it sometimes. Carnations are extremely useful for this purpose, and so also are Roses, of which there are many bushes in the grounds. During the present month and in July, the national flower is uncommonly abundant at Osborne. It may be remarked that upon a few Tea Roses that grow at the foot of a front wall to one of the houses, we were told that there had been blooms during the whole twelve months preceding. During the last two years or so the gardens have been under the care of Mr. Geo. Nobbs.

It will be remembered that the Court was in residence at Osborne last year when the Chinese envoy, Li Hung Chang, visited Her Majesty, and most of the presents he brought from the Celestial Empire are still there. It will be remembered that Her Majesty gave a commission for a painting of Osborne House for presentation to the envoy as a souvenir of his visit. *Inspector.*

PLANTS OF THE VICTORIAN ERA.

HARDY TREES AND SHRUBS.

IT seems the peculiar province of Queens to lend patronage and countenance to our ancient art, for history teaches us that under Elizabeth, Anne, and Victoria, all things connected with the arboreal and floral decoration of mansions, and even ordinary residences, were greatly in vogue.

Though the prim formality of the Tudor age is quite a thing of the past, the influence of the last of the Stuarts remains by us in many formal mansions with their attached pleasaunces and gardens, all eminently characteristic of the age which created them; and when the Victorian age passes into the region of history, it will be found, more than any that preceded it, to have been a period in which horticulture has flourished.

Nurserymen and others have, at great trouble and ungrudging expense, sent out pioneers

into new countries and districts, ransacking the world as it were to find new or little-known plants wherewith to enrich our garden-flores. It is to call attention to and curiously describe some of these that I now propose, but restricting my remarks to the hardy trees and shrubs that have been introduced to commerce since the Queen's Accession in 1837.

At no period in modern times has the professional hybridist been more active, for no sooner has a new actor been introduced upon our stages, or a new subject planted in our nurseries, than it has been taken in hand, and made all the possible use of it could be, and we have resulting a vast accumulation of new and improved forms of already existing trees and shrubs, so that at the present moment, instead of a paucity of subjects to select from, the gardener, more especially the landscape-gardener, is embarrassed with a plethora of suitable plants and trees out of which to choose the most fit for his purpose.

To take the Clematis, for instance: what undreamt-of results have accrued since Thomas Cripps in Kent, and G. Jackman in Surrey, set themselves systematically to improve these fine climbing plants! One of the first was Clematis Hendersoni, which in our days would be hardly looked at, yet when it flowered for the first time at Chandler's nursery in the Wandsworth Road, it was thought much of, and was named in honour of its raiser from seed, after Mr. A. Henderson, of Pine-apple Nursery. But then all that could be said for it was, that it was a trifle larger and brighter in colour than then known kinds—but it is worthy of notice, as doubtless it has had a share in the production of some of the fine hybrid varieties that now adorn our gardens. Another sent us by Von Siebold in 1836, but not in commerce till at least three years later, *C. florida*, lends itself freely to the skill of the hybridist. Now we have upwards of 100 fine kinds to select from, all produced in the Victorian Era.

The average Briton loves to "cover his house" with something, climbing plants by preference, otherwise paint. My father planted one of the first *Glycines* (*Wistaria*) that was raised in England, and before I was a man it had covered three sides of a large house, and had a main stem as thick as my body. It flowered, unless hard hit by late frosts, without foliage, on the south wall, early in May, and again in the autumn, and is doubtless one of the very finest of all our free-growing ligneous climbers; it, however, though uncommencing, was introduced three years after Waterloo, but could hardly be met with in nurseries till after the Queen's accession, while its delicate white variety did not reach us till seven years later. Veitch's Virginia Creeper, *Ampelopsis Veitchi*, another indispensable climbing plant, was introduced by the late J. Gould Veitch, and was first described in these columns. It is the very best self-supporting decorative plant for our walls that we possess, as well as one of the most popular.

Among handsome-leaved trees, Acer *Negundo variegatum* stands conspicuous. It, I believe, originated from seed (?) in Van Houtte's nursery, in Ghent, and sprang immediately into general favour—and now we have the purple-leaved Plum, as well as the noble purple Beech to plant in marked contrast; while another useful Ametaceous plant, the Filbert, has given us a rich purple-leaved sort, all within the famous sixty years we now commemorate. Among other plants used for wall-screens or to cover unsightly fences, we have two that give us their bright yellow flowers in winter and early spring, *Forsythia viridissima* and *Jasminum nudiflorum*, both of which have been introduced to our gardens since '37 from China, and giving their blossoms in a flowerless season are a most welcome addition. These are very closely followed, in the south at any rate, by the brilliant indorecence of the *Berberis Darwini*, introduced just ten years after Her Majesty's accession by Mr. Lobb; and soon after we had two more grand *Berberis*, *Mahonia japonica* (Beali), and *M. nepalensis*, though the latter is not often seen, as it requires a wall or fence to enable it to resist our wet cold winters. In passing, I must

pause to note the lovely hybrid, *B. stenophylla* ×, sent out, I believe, by Messrs. Veitch.

Collectors have been so very active during this period that we have literally an *embarras de richesses*; and when we come to consider that Japan was opened to commerce, British Columbia and California explored, each of which countries teems with new and beautiful plants, shrubs, and trees, this need not cause us to wonder.

From California and British Columbia, and still further north from the wind-swept plains of Oregon and Nebraska, we got, through the aid of Russian explorers, the Nootka Sound Cypress, *Cupressus nootkaensis* (usually called *Thuopsis borealis*); and Scotch collectors sent home seeds of the elegant Conifer, named after the late Charles Lawson, *C. Lawsoniana*, and this

be appreciated from its great vigour and beauty, combined with extreme hardness.

To flit from America to Europe, the grand Crimean Fir, *Abies Nordmanniana*, must be noticed, as it is very hardy, grows to a great size, and assuming a compact, massive pyramidal outline, is most useful to the landscape gardener. Colonel Duncan Cameron, of the Royal Artillery, sent some small seedling specimens in pots to his sister, the late Mrs. Schreiker, during the Crimean war, and they are now quite features in the landscape, though, perhaps, too abiding mementos of that costly struggle. Then we have *Picea pungens glauca*, with its branches densely covered with frosted silver needles, that at once arrest the notice of even careless observers. In marked contrast, we have one of J. G. Veitch's many

nubigenous, introduced by William Lobb in 1849, is another Yew-like Conifer, but it is not hardly enough for general use. *Libocedrus* is another genus new to the reign, the Chilean form having been introduced by High Low & Co., of the Clapton Nursery, as recently as 1847. Where it can resist the cold of our winters it forms an unique tree, but cannot do so without shelter.

Writing from the south coast it will not be right to ignore one of the most useful Conifers for planting in positions exposed to the sea-breeze that was sent us by Mr. A. B. Lambert from California, the year after Her Majesty's accession, *Cupressus macrocarpa*. The great drawback to its use is that it must be nursed in pots in its early life, it then too often makes corkscrew roots, and when planted out it grows very rapidly and strong, forming a dense pyramidal tree. Alas, the first strong gale is apt to blow it clean out of the ground [unless it be rocky. Ed.] if not staked and sheltered. I have known specimens 10 to 12 feet high thus ruined. Both for its adaptability for sea-coast planting, and for its rich green colour, this Conifer was a decided acquisition.

Before concluding the long list of Victorian Conifers, the Japan Cedars (*Cryptomeria*) must be mentioned. The first we had came to the Royal Horticultural Society through their able collector, Robert Fortune; then we had an improved, and more dense form, through Thomas Lobb, in 1853; and in 1867 Mr. J. G. Veitch sent us *C. elegans*, a variety of very easy propagation from cuttings. It is bright green in summer, of a warm bronzy hue in winter, and, therefore, most useful to contrast with golden *Euonymus*, golden Conifers, and other bright-hued shrubs, in making our parterres gay and interesting in mid-winter. Without doubt the most generally useful and finest Conifer introduced to commerce in the reign, was the *Thuja Lobbii* [which turns out to be the original *T. plicata*. Ed.] the most brightly-coloured and vigorous of all the *Arbovite*. This was sent us in 1853 by William Lobb, then collecting for Messrs. J. Veitch & Sons; and though it has no fewer than three other names, let us keep in gardens the one that preserves the name of an intrepid, energetic, and painstaking pioneer among modern collectors.

There are two more Conifers that must have at least a mention, though neither has taken hold on public taste. *Saxe Gotheri*, conspicuous, named in honour of Prince Albert, and *Picea patagonica*, named after Captain Fitzroy, Commander of the *Beagle*, both being introduced from the extreme south of the S. American continent; and from this region also one more Victorian Conifer hail, the *Prumnopitys elegans*, which may be called the Plum-bearing Yew, as it gives in its native country fruits which are eaten by the natives, and are described as resembling a Sweetwater Grape, but with a stony seed like that of a Cherry. *Esperienze*.

(To be continued.)

FIG. 150.—SWISS CHALET AND ROYAL CHILDRENS' GARDENS AT OSBORNE. (SEE P. 398.)

varying almost indefinitely from seed; an old friend of mine going the length of saying that in a bed of seedlings it would be difficult [impossible, he might have said. Ed.] to find two plants exactly alike. We now have more than a dozen distinct and exceedingly useful varieties to enrich our *Finetums* for cemetery work, and in a small state used as pot-plants, or to fill window-boxes, particularly the golden form "Jutea," and the compact pyramidal variety, *erecta viridis*, raised by Anthony Waterer. Now I am among the Conifers I am puzzled to make a judicious selection from the many introduced by Fortune, Jeffery, Lambert, and others, during the Queen's long reign. *Tsuga Albertiana*, but more properly called *Tsuga Mertensiana*, thus named in honour of the lamented Prince Consort, has in all probability come to stay, and though at present foresters do not think much of the value of its timber, it will always

introductions from Japan, *Picea polita*. The lovely *Cedrus Deodara*, unless in favoured spots, seems anything but happy in our island-home. Among later introductions, we have few more unique in character than one introduced by Mr. Maries for J. Veitch & Sons, and named after that well-known name, *Abies Veitchii*. This might be described as a miniature form of the lovely but tender *Abies Webbiana*, as it has erect cones of a rich brown-purple colour, though its foliage in size and colour differ from that fine Fir.

Leaving the Conifers proper, we have other allied members, introduced to gardens since 1837, in *Cephalotaxus*, all from China and Japan, for the one that came to us in that auspicious year was once popularly called *Taxus Harringtoni*, though really a fastigate variety of *Cephalotaxus pedunculata*. I cannot claim for them a high position, as they are only low-growing shrubs at the best. *Podocarpus*

NEW OR NOTEWORTHY PLANTS.

DENDROBIUM VICTORIE REGINE, *n. sp.*, *Lober*.*

This is doubtless one of the most wonderful *Dendrobium*s, both for its beautiful blue colour and for free flowering, and one that will soon be a great favourite with Orchid collectors. It grows at an altitude not lower than 2000 metres (6000 feet), and the temperate house suits it best.

Its branching stems produce great numbers of richly dark blue and white blossoms borne in trusses, and lasting in bloom for several weeks. The flowers are over an inch in diameter, the sepals and petals at

Dendrobium Victorie Regine, n. sp. Endobium, arti u latum, articulis clavatis; foliis ovato lanceolatis, cuneatis, floribus pollicibus in glomeratis, 3-12 floribus, sepalis lanceolatis, externis basin basin coloratissimis connatis petalis ovatis, obtusis breviter acuminatis, labello indiviso e basi angustata oblongo-ovato, acuminato, flamma exserta albamina basi crispata, alba, antennis cartilagineis cordatis rhynchi labellumque videlicet, basi albis, calice ovato, gemma viride.

the base are white, with a great blue blotch at the edges, the lip ovate oblong, and of the same colour. The plant is dedicated to the Queen in commemoration of the Victorian jubilee, and is without doubt one of the finest of all Dendrobiums. *A. Loker, Manilla, April 20.*

PLANT NOTE.

EREMOSTACHYS LACINIATA VAR. IBERIBA.

The typical species, *Eremostachys laciniata*, is a little-known herbaceous plant from the Levant, rarely met with in cultivation. It has yellow flowers in verticillate spikes which appear in June and July; the plant grows about 2 feet in height, and has long oblong lanceolate and deeply-cut leaves. The plant under notice is a new variety of the type, and is in flower at the present time in the Woking Nursery. It is superior to the type, with long simple stems growing to a height of 1 to 5 feet, with whorls of large deep crimson flowers; the upper lip of the corolla being purplish-red, and the lower lip deep crimson. The stems and flowers being covered with a white silky tomentum. It is quite hardy, and appears not to be particular as to soil. *E. S.*

ORIGIN OF MARÉCHAL NIEL ROSE.

The wonderful stories which get into the daily press in all matters relating to horticulture have been well exemplified and exposed in the columns of your contemporary, the *Gardeners' Magazine*, in which a paragraph is cited from one of the dailies in which there are about as many inaccuracies as it is possible to crowd into a small space. It is so very good that it is a pity that all Rose growers should not know it, this is the story:—"It was the beautiful Empress Eugénie, in the days of her splendour, who named Maréchal Niel Rose. When General Niel returned from the scene of his achievements in the Franco-Prussian War, a poor man gave him a basket of lovely pale yellow Roses. As a remembrance of this gift the General had a cutting struck from one of the blooms, and when a charming stock had grown up, took the plant to the Empress Eugénie. She was delighted both with the gift and the gallant donor, but was surprised to learn that the Rose had no name. "Ah!" she said, "I will give it a name; it shall be the Maréchal Niel." In this sprightly and gracious manner the gallant soldier was made aware of his elevation to the coveted office of Marshal of France.

I need hardly dwell upon the anachronisms in this paragraph, and would not have noticed it at all, but that I happen to know, perhaps, a little more about it than anybody living. I was in Paris the summer before it was sent out, and a well-known Parisian Rose-grower, who was at that time sending out annually a number of new Roses, expressed his wish to see me. He breakfasted with me one morning, and brought with him a box of Roses; they were mostly reds of various shades, and if I recollect rightly, that fine Rose, Dr. Andry, was amongst the number. Just at the bottom of the box I espied a glorious Rose. "What is that?" I asked. "Oh! it is a Noisette, Maréchal Niel," and he expressed some astonishment when I asked, "Why that is worth all the rest put together." He talked about it, and I said, "My advice to you would be, if you have not got a large stock, to increase it as much as you can, come once to Eng'land and exhibit it at one of our Rose shows, for I venture to say you will make a small fortune of it." He thanked me, but I did not see much sign of his agreeing to my advice. I did not understand his reluctance at the time, but soon afterwards found out what I believe was the cause; the Rose is said to have been raised from Isabella Grey by Pradel, and a portion of the stock had passed on to the nurseryman I had mentioned, and thus he was not in a position to announce himself the sole distributor of it, and that of course prevented him from profiting by my suggestion. He sent out a number of Roses that year,

and offered Maréchal Niel as a gratis plant to those who took the set he was distributing, and thus what we may truly call the "golden opportunity" was lost. As soon as it was sent it took everybody by storm—it was sought for on all sides; and, up to the present day, remains one of the most popular Roses in cultivation. This is a simple story, and not so romantic as that quoted by your daily contemporary, but having one element which that lacks—truth. It is a curious thing that, though Maréchal Niel has been upwards of thirty years in cultivation, nothing has since been raised at all comparable to it. *W. D. Rose.*

THE WEEK'S WORK.

THE HARDY FRUIT GARDEN.

B. H. W. WARD, Rayleigh, Essex.

Watering Wall-trees.—Reiterating my remarks as to the necessity for affording water liberally to fruit-tree borders, and especially to those in which wall-trees are grown, say once a week to the latter, and rather less frequently to the other, the warmer aspects will require most water during the period of active growth, and when fruits are swelling; at which time diluted liquid manure given alternately with clear water until the fruit begins to change colour, is of great assistance. If liquid manure cannot be obtained, a good substitute will be found in the XL All Liquid manure, a concentrated clear liquid possessing great fertilising properties. Standard fruit-trees and bushes growing in light or shallow soils are much benefited by this sort of treatment, as also Raspberry plantations and Strawberry beds directly after the plants have set their blossoms.

Strawberries.—The necessity to protect the fruits from the birds is present in most country gardens. Raspberries and Strawberries which have to be sent by rail or road should be gathered rather under ripe, otherwise they will not travel without damage, no matter how carefully they may be packed. Forked sticks long enough to keep the netting about 6 inches above the plants should be stuck into the Strawberry-beds to support it, otherwise thrushes and blackbirds will peck the fruits. The time has arrived for taking runners for fruiting in pots from February next and onwards. For some years I have not layered the runners into 60's, but placed them at once on the fruiting-pots instead, and with very satisfactory results, including the saving of much valuable time. For those plants that are to fruit early, small 32's form a suitable size of pot, large 32's being employed for late fruiters. The new variety Royal Sovereign is a first-early Strawberry, both as a forcer and out-of-doors; and in addition to earliness it has size, good form, solidity of flesh, and good quality to recommend it. Sir Joseph Paxton is, as everyone knows, a good all-round Strawberry, and large numbers of these varieties should be layered if they are already found in quantity in the garden. Whether small or large pots be used, they should be new ones that have been immersed for a short time in water, or old ones washed clean. It will suffice to place a hollow crock on the hole, the hollow side downwards, and cover this with smaller crocks to the depth of an inch, and over these a layer of turfy bits and a sprinkling of soot. This done, fill the pots to within three-quarters of an inch of the top with good loam, and ram this moderately firmly. Should the loam be poor, add a quarter of the whole to a common garden barrowful of bone-meal or horse-droppings, or an 8-inch potful of bone-meal to a common garden barrowful of the loam. Stand the pots when filled, between alternate rows, and secure one strong runner in the centre of each pot, with a hooked peg or a piece of stone. In dry weather the soil in the pots must be afforded water almost daily, and if a sprinkler can be given the runners every evening, rooting will be hastened.

PLANTS UNDER GLASS.

By G. H. MAYCOCK, Gardener, Luton Hoop Park, Luton.

Gardenia floribunda.—These cuttings which, taken in early spring and potted into 60's when rooted, may now be shifted into 4's for flowering in the spring of next year. Let the plants be syringed night and morning with clear rain-water, and the pit in which they are placed be maintained in a moist warm genial state. If rain-water be not available, it will be advisable to syringe or dip them overhead once a week into

water containing an insecticide, always laying the plants afterwards on their sides to drain. The potting-soil may consist of fibry loam one half, peat one half, with sharp sand, and charcoal in a small state added to these materials. Shade the plants until roots appear in the new soil, and then gradually inure them to full sunshine.

Gloxinias.—The amount of water applied to the soil of the early batch may now be lessened, as these plants are passing out of flower. If the tubers are to be kept for flowering early in the spring of next year, place the pots in a cold frame, and afford sufficient water as will keep the tubers plump after the leaves have dropped naturally. The seedlings of this year's raising will now require to be potted for the last time. A low-roofed warm-pit makes a suitable place for these plants, the stage being covered with a layer of freshly-gathered moss, and the plants stood thereon. Shade the plants from strong sunshine.

Cyclamens.—If these plants were potted as advised in an earlier Calendar, they may now be placed on a cool ash bottom in a cold frame, affording them ample space, so as to let the foliage develop without crowding. Keep these plants also shaded from strong sunshine, and on warm nights in July and August remove the lights, replacing them in the morning. A moderate degree of humidity should be maintained about these plants, and thrips not allowed to gain a foothold on the leaves.

General Remarks.—Plants of *Libonia floribunda* should be shifted before becoming pot-bound, and removed to a cold pit or house, the syringe and clean water being in daily use to check the irroards of red-spider, the only pest with which the plant is troubled. Rooted cuttings of *Eupatorium* should be potted into 4's, and the shoots stopped occasionally to induce bushiness. An abundant sowing of *Rhodantha Maoglesi* may now be made in 4's for late summer flowering, sowing thickly on the surface of the soil, which should consist chiefly of sandy peat and leaf-mould. The number of plants left to grow in a pot of this size may not exceed ten. Azaleas having in most cases finished growth for the season, may safely be placed out-of-doors, with a temporary framework of laths or tiffany over them, letting this remain for three weeks or a month. If the plants can be plugged in coal-hes or sand, the amount of water required will be lessened, and the roots, which are hair-like, will not suffer from getting dry, as they need most when the pots are exposed to the air. If that cannot be done, shade the pots into others one or two sizes larger, or shade them with a tile, piece of bark, or a board. Achimenes now showing flower may be tied out, if in pots, or regulated if in baskets. Use but few supports and ties, and make these as little visible as possible. Plants of *Fraucoa ramosa* that were raised from seed in the month of February may be put into cold frames. At one time this pretty plant was a great favourite with the Queen.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Oxford.

Species which have Recently gone out of Flower.—The plants of *Odontoglossom citrostrum* are at Burford growing with freedom, and as the roots commence to push from the newly-formed breaks, is then the time to repot all that may require more root-space. *O. citrostrum* is a plant that makes but few roots, and consequently it is not desirable to use peat and sphagnum-moss in large quantities in which to root. Let the plants be hung up in a sunny part of the Mexican or Cattleya-house, and as the growths advance, afford water freely at the root, and maintain the air in a moist state. On sunny afternoons, on closing the house, afford the plants a light overhead syringing. *Thunia Marshallii*, *T. Bensoniae*, *T. Veitchiana*, *T. alba*, *T. Brymeriana*, and *T. candidissima* should be afforded sunshine in abundance, or the flowering growths will not mature. *Thunias* may be finished up in an early viney, provided the shade is not very dense. Until the leaves of these plants begin to change colour, the latter should be afforded water occasionally, and the leaves examined weekly, red-spider being apt to infest them. Should any of these acari be noticed, syringe the plants with a strong soap-suds made from soft-soap and rain-water, the mixture being used at about 90°, and the plants be rinsed afterwards with clear tepid water. After the fall of the leaves keep the plants in a dry house, where the temperature does not fall below 55°. *Thunias* which may not have flowered this season, and have grown to a great length, should be treated in exactly the same manner as those which have flowered.

Plants of *Cattleya Mossie* and *C. Mendii*, if they have begun to grow at top or root, may now be reported or top-dressed. Plants of *Lælia purpurata* should be placed in the coolest part of the house in order to keep growth dormant as long as possible, it often happening that plants which begin to grow at the season will produce flowers, while those that start later invariably bloom at the right season. When the breaks of *L. purpurata* have reached a length of a few inches, new roots are emitted from them, and then is the proper time to report any that is standing in need of more rooting space; and equally so *Lælia-Cattleya Phoebe*, *L.-C. Latoua*, and *L.-C. Hippolyta*. The plants of *Miltouia vexillaria* which have passed out of flower may be removed to a light position in the cool-house and freely ventilated, but affording them scarcely any water till growth has recommenced, as the roots being almost dormant, readily decay if the potting materials be moist. *Miltouia Phælopsis* may be reported, the young breaks beginning already to push forth new roots; avoid over-potting this plant, afford plenty of drainage, and elevate the plant so as to bring it well up to the roof of an intermediate-house. *M. Rozcii* may also be reported, and placed at the cooler end of the East Indian-house. Both species require only sphagnum-moss in which to root. *Oncidium*s, such as *O. Marshallianum*, *O. concolor*, *O. nuttiganum*, and *O. Olivaceum*, should be placed in a moist, cool house, and kept rather dry at the root until growth starts anew. *Masdevallias* and *Odontoglossums*, when out of flower, should not be kept very moist at the root, or the decay of the latter will occur, the leaves of the *Masdevallias* be disfigured by black spots, and the old foliage of the *Odontoglossum* turning yellow, and falling off.

THE FLOWER GARDEN.

By CHARLES HERRIN, Gardener, Droppore, Maldenhead.

The Herbaceous Border.—The refreshing rains of the past week have caused a rapid growth in most of the plants, and much attention will be required in the matters of staking and tying from time to time. The *Mischocanna* varieties of tall growth will also require to be staked and tied in order to preserve the flower-stems in an erect position. The earlier-flowering varieties, if desired to be made dwarfer than usual, may have 5 or 6 inches of the points taken off, which will induce a bushy habit; and although the spikes of flowers may not be so long as the unstoppered ones, for border decoration they are even more effective. The Double White Rocket (*Hesperis matronalis alba pleno*), has flowered well this season; it is a good old-fashioned border plant, and one that is very useful where many cut flowers have to be supplied. As soon as flowering is past, the flower-stems should be cut away carefully to within 6 inches of the base of the plant, preparatory to transplanting the latter as soon as new growth commences. This should be done annually if a stock of healthy plants of this sweetly-scented perennial has to be maintained. *Doronicum*s of the larger flowering species, as *D. plantagineum*, and *D. excelsum*, having now passed out of flower, the old stems should be cut away; and when an increase of the plants is desired, this may be done by division of the root at the present time. The smaller variety, *D. austriacum*, is still flowering abundantly, and gives promise of continuing to bloom for some time yet. Although a smaller and rather later-flowering species than the preceding, *D. austriacum* is a useful plant, and the blooms continue to be produced for a long period of time.

Saxifraga umbrosa.—London Pride is not a plant to be despised in the herbaceous border. Occasional clumps or edgings of it are effective especially while in bloom; and the flower-spikes are light and elegant in appearance forming good material for filling vases either alone or in association with other flowers.

Anclusa Italica is a free-growing plant, with flowers of an intense shade of blue, which are freely produced on spikes from 2 to 4 feet in height. It continues in flower from the present time, more or less, throughout the summer. The growths require to be kept erect by tying them to small stakes or bamboo canes placed so as to be as much out of sight as possible.

Carnations are fast throwing up their flowers, and where large blooms are required, the small side-flower buds should be rubbed off early, and neat sticks afforded to support the flower-stems. Where Carnations are grown together in beds expressly for show or cutting purposes, it is a good method to stick in twigs of the Birch or those of other trees around the

plants as support to the flowers. It occupies less time than tying each stem separately, and answers the purpose just as well, moreover, the flowers are more readily gathered.

FRUITS UNDER GLASS.

By F. HARRIS, Gardener, Eastnor Castle, Ledbury.

The Early Vinery.—If any of the bunches still remain on the Vines, the air must be kept cool and dry, and if the fruit must be kept in good condition for any length of time, shading should be used on days that are hot and bright; and if the border, on being examined, is found to be getting dry, a fairly liberal amount of tepid water should be afforded on a bright warm morning, which will have the effect of keeping the berries plump for some time after being fully ripe. As soon as the Vines are cleared of the bunches, throw the lights as wide open as possible, and afford the Vines a heavy syringing with strong soap-suds in the evening, followed by another with clean water the next morning. By doing this occasionally, red-spider will do but little harm, and the foliage will remain in a healthy state up to the last.

Late Vinerics.—Vines with ripening fruit will require to have the foliage fastened back by degrees, so that it will not shade the white Grapes, the lateral shoots being allowed to run without, however, causing undue crowding. On the first appearance of red-spider on the leaves, use a small piece of sponge and some soapy water for its removal. If the berries of Foster's Seedling and Madresfield Court crack their skin, keep the border dry beneath the Vines, and allow the laterals to run for a time till the malady is cured. I have found that the most critical time for these two varieties is when the colouring of the fruit commences, but once safely over that period, there is little danger of cracking.

Late Vinerics.—The thinning the bunches will in most instances have been finished. This operation should be followed by a thorough soaking of the borders with liquid-manure mixed with boiling-water. It is likewise advisable to syringe the Vines with clean rain-water in the evening occasionally. Let the laterals be secured to the wires, and where it can be done without crowding, allow these shoots to extend themselves. In all cases it is well to ascertain if a second thinning of the bunches be not called for, taking out a berry here and there, but having an eye to perfect compactness of bunch. Lady Downes, a variety that is apt to scald, should be afforded a slight amount of front and back ventilation the last thing at night, which ensures a dry, buoyant atmosphere in the morning, when, in the majority of cases, scalding chiefly occurs.

THE KITCHEN GARDEN.

By W. POPE, Gardener, Highclere Castle, Newbury.

Mulching Vegetable Crops.—From the present date mulching will play an important part in the vegetable garden if this be situated on light or shallow soils, it being almost a prime necessity in unusually warm summers, and one which always pays for the doing. On heavy land mulching is not so important, provided a friable tilth can be secured by the use of the hoe, which greatly aids in checking the evaporation of moisture from the land. Runner Beans, Peas, and two kinds of vegetable crops that are much benefited by a liberal mulch of spent bodied, or Mushroom bed dung placed along each side of the rows, a thorough soaking of the land being afforded previously. Never apply water in dribbles and thereby attract the roots to the surface only to perish, but apply water in abundance, at intervals of three weeks or so. The Cauliflower is also benefited by a thick mulch of rich, half-rotten stable or cow-manure, as are also Globe Artichokes, Leeks, and freshly-planted Celery, a slight sprinkling of salt being applied before the manure to the last-named crop. The short grass from the mowing machine may be usefully employed in mulching Carrots, it being easily put on the land, and if it be done in good time, it is useful as a preventive against wireworm. It is not generally advisable to mulch Onion with manure, but to keep the surface well stirred.

Asparagus.—The season of this vegetable will soon be over, the rule in many places being to discontinue cutting as soon as the outdoor Peas come into use. If manure-water and the labour to apply it be plentiful, a good soaking of liquid-manure applied about this date will strengthen the crowns greatly. Failing manure-water, a sprinkling of salt and soot or guano may be afforded the plants in showery

weather, or before water is applied. Keep the beds free of weeds, and secure all the stronger stems to sticks, or to tarred string run along the rows of plants.

Salads.—The consumption of salads being now great, weekly sowings should be made of Mustard, Cress, and Radishes, choosing for the beds a somewhat moist, and yet not much shaded a situation in the garden. Lettuce in variety may be sown once in ten days, thinning the plants early at from 9 to 12 inches apart; a few being also transplanted. Make a sowing of Endive, and thin those earlier sowings as soon as the plants can well be handled.

Peas.—Late Peas should now be sown, choosing No. 15 Ultra, a good and trustworthy variety; it is a rather tall Pea. Dwarf Peas for present sowing are Sutton's Late Queen, or Latest-of-All, which are varieties of splendid quality. Select for this sowing a sunny part of the garden, and one that is sheltered from the south-west. Sow the seeds thickly, preferably in trenches, and cover them with about 3 inches of soil, treading the soil firmly before and after sowing.

THE APIARY.

By EXPERT.

Swarming Hives is an art requiring some little experience, the beginner, as a rule, being apt to make a mistake by putting on his supers long before they are really wanted. This of itself would not be so serious a matter if due precautions were taken to wrap up well, with plenty of warm packing, which in some measure would compensate for the loss of heat over the brood-nest, so useful at this particular time, caused, of course, by the empty surplus space made overhead. On the other hand, it is just as possible to be too late in putting on supers, particularly if the prevention of swarming is intended. Hence the bees have formed queen-cells, no amount of swarming will prevent their swarming out, provided the weather is favourable. Section racks, holding twenty-one 1 lb. sections are the most generally used in Scotland for surplus chambers when comb-honey is wanted. It pays to use full sheets of comb foundation in the sections at all times. My own preference is for the four-way sections with slotted metal dividers. If sections can be had with built out clean combs left over from the previous season, a single row of these put in the centre of the rack, acts as a bait, and will entice the bees more quickly into taking possession. Having the rack of sections ready to place on the hive, strip off the quilt, and blow a few whiffs of smoke across the top of the frames. Any brace combs or projections on top-bars should be scraped off, and the rack placed flat down on the frames, care being also taken that no warmth can escape at the junction of hive and section-rack. Now replace the quilt and other wraps over the rack, so as to conserve the heat, and keep all warm. Swarms, when received from a long distance, should be fed as soon as they arrive, and when put into their new hive do not neglect to give them a pint of syrup, or thinned honey, for the first two or three nights. This will repay the bee-keeper who aims at results the first season. When living swarms on full sheets, see that each sheet of foundation is properly fixed or wired in the frame; another important point in getting good combs built out straight and even, is to see that the hive stands level, and that no more frames are put in the hive than the bees can fairly cover. Wraps must also be regulated according to temperature. Some days—and nights too—a single thickness of carpet is enough; at other times, three thicknesses is not too much. Use your own judgment in this matter.

Ventilation.—In very hot weather, if the bees exhibit signs of distress by hanging out, give ventilation at the bottom of the hive by raising it up a little from the floor-board, lowering it again at night. Hives with sliding-floors may have them withdrawn a little, or lowered at the front during the hottest part of the day; entrance also should be shaded if it can be conveniently done. Sometimes it is beneficial to remove the wrappings of supers and to slightly raise the roots of the hives in order to allow a current of air to play about, and so cool the surplus chambers. It is not often useful to take all these precautions, except in exceptionally hot summers, when more care than usual is required; a little extra attention, however, at such times is well repaid. It should be borne in mind that bees bred from eggs laid after the end of June, render no assistance in storing surplus honey (except in richer districts), so that the brood nest becomes a minor consideration after this month is out. The bees are supposed to be already worked up to full strength, and for the next few weeks all our attention is required in giving them employment.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction in these pages, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY,	JUNE 22	Queen's Commemoration Day.
WEDNESDAY,	JUNE 23	Victorian Era Flower Show, at the Crystal Palace. Richmond (Surrey) Horticultural Society's Show. Royal Agricultural Society's Show, at Manchester (6 days).
THURSDAY,	JUNE 24	Colchester Horticultural and Rose Show.
FRIDAY,	JUNE 25	Maidstone Horticultural and Rose Show. Royal Botanic Society, Lecture.

SALES

FRIDAY,	JUNE 27	Imported and Established Orchids at Protheroe & Morris' Rooms.
---------	---------	--

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—61° 8'.

ACTUAL TEMPERATURES.—

LONDON.—June 16: Max., 67°; Min., 52°.
PROVINCES.—June 16 (6 P.M.): Max., 67°, London; Min., 48°, Aberdeen.

On June 18, 1887, we had occasion, in connection with the fiftieth anniversary of Her Majesty's accession, to review the progress of horticulture during the half-century. We had a like opportunity on January 3, 1891, the occasion of the Jubilee of the *Gardeners' Chronicle*. Now, in 1897, when we are all jubilant over the sixty years of the Queen's reign, and the progress made in it, we might advert at length to the same subject, but that the iteration might be tiresome.

Every gardener of mature age must now be familiar with the general progress of his art, or if he is not, we may refer him to the two articles above mentioned. It may suffice to allude to the substantial general progress made since 1837, as shown in the article immediately following, and to indicate a few particulars in which advance in matters horticultural has

been made since 1891. The Royal Horticultural Society has been rejuvenated. The culture of Grapes, Tomatoes, Palms, &c., for market, already vast at that time, has become even more colossal since, and the Rochfords and Ladds, and some others, may be cited as carrying on a "bigger thing" even than our transatlantic friends can show. Roses and Orchids are more in fashion than ever; Cannas have come to the front, and bid fair to be the originators of as great and important changes as are manifested by the tuberous Begonias.

After years of remonstrance and persuasion we have had the pleasure of seeing, through the influence of the new County Councils, a beginning made with the elementary education of our rural lads and, we may add, lasses, in horticultural and educational matters. Though we have laboured so long in the field, we are far from attributing this result to any efforts of our own; but in any case we may heartily rejoice that at length something has been done. As compared with what has been accomplished in America, in Germany, in France, in Belgium, what we have effected so far is infinitesimal, and instead of being in the forefront of educational progress as we ought to be, we are the veriest laggards.

With all our resources we are allowing ourselves to be beaten in some things by countries much smaller and with much less means than we can command. The last great war was won in the main by the superior education of the Germans. It will be the same with us in the field of commercial horticulture and agriculture, if we do not heed the signs of the times. We are glorying, and with justice, in the Victorian era and its progress, but if we wish to maintain our position, we must, in the coming years, pay much more attention than we have hitherto done both to general and specially to technical education.

POSSIBLY no retrospect in these Then, and Now, pages in connection with the Diamond Jubilee would be considered complete which failed to take note of the material progress of the nation; that progress in the acquisition of wealth which has enabled the masses to indulge in luxuries of life unknown to them before Victoria mounted the throne and took possession of the hearts of her subjects, who, numbering some 18,000,000 in 1837, to-day show an increase up to twice that amount. The luxuries of life for them consist of and more better food of all kinds, including many sorts of vegetables and fruits; a plentiful supply of flowers and plants, improved drainage urban and suburban, and of many other matters which can find no place here. Month by month we give tables relating to the food supply, and of that connected with the raw materials employed in our great manufactures; week by week we give a list of market prices well worth consideration; to-day we give—first, tables relating to imports of foreign and colonial produce, to which are added for comparison the equivalents, as nearly as possible, entered for consumption at the present day; added to which, again, is a sectional table of imports and values, together with the same for the past five months of the present year of 1897—the sixtieth year of HER MAJESTY'S reign. (The prices not being given in the earlier Returns, the comparison is faulty to that extent, and the figures are doubtless approximate only; the Customs' dues on all would be of no assistance, and are therefore deleted.)

Necessarily, we can only give a selection from the quaint-looking Board of Trade Returns for 1837—the whole of which cover but six folio pages—the present day returns cover 140 pages, or a decent-sized volume! The latter tables relate to exports of British and Irish produce and manufactures—complete so far as it goes (which is not very far, but all that is available). The remainder of the figures stand in the same relation as do those relating to the imports. The following is the important table:—

	IMPORTS.	1837.	1896
Butter cwt.	266,659	3,667,947
Cheese	232,255	2,244,235
Eggs	74,790,078	13,244,893
Cocoa lb.	1,418,631	24,225,428
Coffee	26,594,066	27,480,592
Tea	31,872,516	206,668,791
Sugar cwt.	4,355,240	30,547,540
Corn qtr.	635,732	114,219,407
Wheat-meal and other kinds cwt.	40,331	21,661,320
Fruit, dried	316,480	1,745,724
Lemons and Oranges, value £	2,291	1,369,674
Metals, iron bars, &c. tons	13,470	178,175
.. copper, &c. cwt.	56,018	1,000,469
Seeds: Flax, Linseed, Rape bush bush.	4,352,409	22,173,072
.. Clover cwt.	124,967	405,071
Silk, raw and manufactured lb.	4,908,455	1,754,800,256
.. piece No.	134,714	7 1896
Cotton-wool lb.	378,019,680	1,754,800,256
Wool, sheep or lamb's	43,148,297	713,579,173
Spirits gall.	4,416,805	8,174,296
Wines	5,563,182	15,861,251
Tobacco lb.	22,549,388	68,503,012

	IMPORTS.	1896.	5 months, 1897.
Animals, living (for food)	10,438,699	4,396,451
(A.) Articles of food and drink—duty free	146,301,768	66,230,543
(B.) Articles of food and drink—dutiable	25,693,706	10,286,177
Tobacco—dutiable	4,370,670	1,629,089
Metals	29,464,786	8,853,491
Chemicals, dye stuffs, and tanning substances	6,784,845	3,348,179
Oils	8,446,709	2,887,921
Raw materials for textile manufactures	74,766,039	37,909,611
Raw materials for sundry industries and manufactures	47,240,919	16,867,171
Manufactured articles	81,250,433	36,532,133
(A.) Miscellaneous articles	15,036,482	5,833,296
(B.) Parcel Post	1,912,348	438,656
Total value £	441,807,335	189,221,479

There are enough items and figures to satisfy most folks in the above attempt at precision. A look down the items column will show in a moment how great is the difference between then and now. Our friends will perceive that, with the exception of Oranges and Lemons, no other fresh fruit is tabulated. To-day, or, rather, in 1896, we imported for home consumption, fruit to the value of £2,170,394. We grow the counterpart of all at home; but what is imported, excepting Canadian, is what may be termed "early" fruit. Of vegetables of all the sorts grown at home, we imported during twelve months to the extent of £2,874,388. About these figures there is something really magnificent, looking at the totals. Now take

* Great hundreds.
† Now given in cwt., and exclusive of Beans and Peas

EXPORTS.

To far-away seas in 1837 British ships were frequent visitors; to-day the sea is covered with British ships carrying imports and exports, for millions of Englishmen, Irish, and Scotch are colonising wherever that is found to pay—from Manitoba to Tasmania—round the globe, ever in advance of a rising sun. Every civilised nation in the world is engaged in getting ready produce for "the world's mart;" the fruits of every clime find their way to Covent Garden and other markets; our streets are paved with wood from New Zealand, Australia, and Canada; and ores reach us from both frigid and torrid zones.

Our colonies are the envy of other nations, whose inhabitants by tens of thousands wend their way thither, and so British commerce has turned out to be that great lever which moves the world; the fulcrum made up of pluck and necessity, and all for the world's betterment. Loyal to the nation she governs, our QUEEN's great common-sense has helped forward the civilising mission of this country by every means ready to her hand; and so it has come to pass that men and women in far-off colonies look ever to these islands as to their home, and bless the gentle lady for her many years of endeavour to govern justly and well.

CRYSTAL PALACE FLOWER SHOW.—Amongst the many Jubilee celebrations, the floriculture of the period is not to be neglected, for the Crystal

Palace authorities will hold their Grand Flower Show on Wednesday and Thursday, June 23 and 24, in which the great feature will be a magnificent display of all the flowers and plants specially cultivated during the Victorian Era.

DEPTFORD PARK.—On White Monday this seven-acre plot of prettily-laid-out public park was declared open by Dr. COLLINS, as representing the London County Council, into whose care this fine open space has been given. Part of the old Evelyn estate, the new people's park, lies between the Lower Road and the Surrey Canal, and in our issue for November 16, 1895, will be found several illustrations and descriptions which will suffice to inform the reader in all matters relating to landscape-gardening, as adapted to the site. Surely some memorial might here be erected calculated to remind the little athletes who are certain to make the most of the newly-opened free space that here or hereabouts the great Czar PETER used to disport himself; that by the lawn facing the family mansion of EVELYN, who lodged the young Czar, this young gentleman destroyed the famous Holly-hedge in which EVELYN delighted, in order that he might have an easy instead of a roundabout or rut-tiven road to the river, by the side of which he daily took instruction in the art of ship-building, as taught at Deptford. Surely the idea is well worth entertaining, especially in this year of Jubilee. A memorial of SILVA EVELYN would be even more appropriate.

NEWCASTLE AND DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT SOCIETY.—The monthly meeting of this Society was held at their room, 23, Westgate Road, on Tuesday, June 8, with Mr. JOHN BUTLOCK in the chair. There was a moderate number of members present, and an excellent display of blooms and plants was made. A paper by Mr. E. SHEPHERD, Ashburton Lodge, Gosforth, on Spiræas and Hydrangeas, and read in his absence by the chairman, contained many useful hints on the cultivation of these plants, and its reading was followed by discussion.

A RHODODENDRON SHOW is now being made in the gardens of the Royal Botanic Society in Regent's Park, by Messrs. JNO. WATERER & SONS, Bagshot Nurseries, Surrey. Though it is something like twenty-five years since Bagshot Rhododendrons have been exhibited at this place, previous to that time annual shows had been made there for more than a score of years. The site was originally prepared for a Rhododendron garden, and is very suitable to their display. It is more or less circular in shape, with numerous paths, and comparatively small geometrical beds, most of them having a border of grass around them. The surface of the ground has been left at differing levels, the centre probably being lowest, and the planting in the present instance has been done in such a manner that from any of the corners a view of the whole of the plants is gained. Few species of plants will permit of being transplanted a fortnight before the buds burst into blossom and suffer no check, but the Rhododendron makes a mass of fine close roots that efficiently hold the soil together. The present hot sunshine hurries the flowers past, however, more quickly than is desirable, notwithstanding the whole is covered by a nice tent. The task of maintaining a named collection of Rhododendrons is immense, for seedlings are raised so easily, and they so frequently have qualities equal to many of the named kinds, that incessant revision is imperative. Some of the old varieties nevertheless continue to remain the best in their class. The best of all that have been raised by Messrs. WATERER is probably the variety Pink Pearl that was exhibited recently at the Temple Show. It has flesh-coloured flowers of unusual size. This is not now in bloom, but of the same strain is Lady Clementine Walsh, having large flowers, with white centre, delicately suffused with lilac-pink towards the margin, and green spotting upon upper petal. It produces a bold truss, and is said to be a good grower. G. WATERER,

with paler flowers than the preceding, may also be recommended. Francis B. Hayes has white flowers, marked very conspicuously with chocolate spots or blotches. Jno. Walter, a rich-crimson flowering variety. Mrs. Holford, salmon-crimson; and the older variety, Minnie, are good. Several seedlings that have been planted illustrate the good average quality obtained in them. The show will be continued for a fortnight or so longer.

—The neighbourhood of Hyde Park Corner has this season been gorgeous with Ghent and Mollis Azaleas and Rhododendrons, supplied from Mr. ARTHUR WATERER'S Nurseries at Woking. It is the opinion of all who have seen them, that the present season has surpassed any others in the magnificence of their flowering. It may prove of practical interest to note the following as being amongst the best varieties of hybrid Rhododendrons, which stand on the grass between the carriage-road leading from Kensington to Hyde Park Corner and Rotten Row. A large specimen Barclayanna, deep rosy-crimson; The Queen, pinkish-white, yellow blotch, close, compact truss; Everest-ianum, rosy-lilac, fringed, abundant bloomer; Michael Waterer, one of the best, brightest scarlet-crimson, fine form and habit—very fine specimen plants; St. Simon, a beautiful rich purple-crimson spotted, standing near Albert Gate. In some beds may be noted splendid examples of Mr. W. E. Gladstone, a fine pink; John Waterer, intense glowing carmine, large, and of fine form; also a beautiful plant of Duchess of Connaught, one of the finest white varieties, extra large truss, with lemon blotches on the flower—very attractive. On the north side of Rotten Row are some large specimen plants. Here were noted Marchioness of Lansdowne, pale rose with a black spot—a most distinct and beautiful variety. As companion plants well worthy of mention are Kate Waterer, undoubtedly one of the most distinct and striking, rosy-crimson varieties, with a large yellow blotch; and Lady Grey Egerton, silvery bluish, and bearing a splendid truss. In beds are Sappho, white, distinctly blotched; Stella, pale rose; Snowflake, pure white; Lady Eleanor Cathcart, bright clear rose, with chocolate spots, fine truss—a showy variety; J. Marshall Brooks, a distinct and beautiful variety, handsome trusses of rich scarlet, with bronze eye. A bed planted with, Kalmia latifolia is a new departure; the plants make a good show.

THE GARDENERS' COMPANY.—At a meeting of the Court of the Gardeners' Company, held on Wednesday, Mr. N. N. SHERWOOD was re-elected master, and Sir WILLIAM FARMER and Mr. PHILIP CROWLEY elected usual and reuter wardens respectively for the ensuing year. Mr. WILLIAM GREET, lessee of the Lyric theatre, was admitted to the freedom and livery of the company, and afterwards elected a member of the court. The master's installation and the formal admission of Mr. GREET will take place (by permission) at the Vintners' Hall, on Tuesday, July 6, and will be followed by a banquet.

A BOTANICAL SOCIETY FOR WESTERN AUSTRALIA.—It is the intention of the friends of natural history in the Colony of Western Australia to establish a society of botanists, which shall form a much-called-for bond of union among plant-lovers in this, the most beautifully fertile region of the Continent. The inaugural meeting was held in St. George's Hall, Perth, on May 4, 1897, under the presidency of E. H. WITTENSON, Esq., Minister of Education for the Colony. It was then decided to call the Society the Von Mueller Botanic Society. The following officers-bearers were elected.—Patron, His Excellency the Governor; President, Sir JOHN FORBES; Vice-Presidents, Messrs. E. H. WITTENSON and G. LEAKE; a committee, and a Secretary Mr. J. FUSLER SKENES. On the motion of Mr. BICKFORD, it was unanimously resolved—"That the assistance of the Government be solicited in the direction of a subsidy, by providing rooms, or in the direction of appointing a botanist who is qualified to identify and classify the flora and vegetation of Western Australia."

PARAFFIN-NAPHTHALIN EMULSION AS A PLANT INSECTICIDE.—One part of naphthalin is dissolved by heat in ten parts of paraffin oil. The solution is well shaken with a solution of thirty-three parts of soft soap in thirty-three parts of water at about 85° C. The emulsion thus obtained is very permanent, and fifteen parts of the same diluted with 1000 parts of water gives a very effective solution for destroying insects. *Pharm. Centralbl.*, xxxviii, 242 (*Pharmaceutical Journal*).

MUNICIPAL FLORICULTURE.—It is stated that the Liverpool Borough Parks Committee have had a large number of window-boxes made, filled them with soil and plants, and then generously distributed them amongst the poor inhabitants of that great seaport. How very sensible and practical an act is this, and how admirably does it serve to florally commemorate the jubilee year. It is indeed to be hoped that such a kindly action may not only meet with ample reward, by full appreciation on the part of the poor recipients, but that also the action may be both perpetuated and extended. Parks and gardens committees, as a rule, now do very much to render the open spaces under their control at once beautiful and attractive. But the brightest of gardens still leaves the streets of the poor miserably dull and oppressive. To carry some, if ever so little, of the floral beauty of the garden into these gloomy and apparently God-forsaken thoroughfares is indeed a desirable as it is a kindly act. How strikingly does this practical proceeding at Liverpool compare with the poor effort at kindness made by our London Parks and Gardens authorities when they give away in the autumn the worthless plants that have done duty in their flower-beds all the summer. The poor will fetch them in great numbers, take them home and pot them, only to see them decline and die. Some day we may hope to see our municipal authorities everywhere not only supplying well-filled window boxes to their poor districts, but also giving small prizes later for those best attended to.

CARNATIONS AND PICOTEES.—In the Tyrol, Italy, Spain, and South of France the people grow Carnations and Picotees as window-plants, or to hang down through the balustrades or iron-work of a balcony; but they never think of showing them off as we do by tying the flowers up with their faces turned to the sun. They just hang *négligé*, and look ever so much nicer. Probably if competitions were instituted, they would tie up the pretty blooms *à l'anglais*. When you look upwards towards a window or a balcony, the Carnation is face to face with you, and the flowers hanging their heads in this way are not so liable to be spoiled by rain and sunshine. We know how soon bright sunshine takes the colour out of the flower; and to make it all the harder for them, we plant them in beds exposed to the sunshine the whole day. Is it not just a little bit stupid?

THE GARDEN AT THE VICTORIAN ERA EXHIBITION.—We learn that in addition to the planting by Messrs. LAING, other portions of the gardens were planted by Messrs. WARE; and that the necessary alterations and improvements in the gardens generally have been made by Mr. W. HITCHCOCK, the head gardener, to whom much credit is due.

NEW CHALLENGE CUP.—The Croydon Horticultural Society has been successful in obtaining by special subscription a very handsome new cup, to replace the last, which was won outright in 1896 by the Rev. J. H. PEMBERTON, after having been in competition for nine years.

PELARGONIUMS AT LEWISHAM.—We had recently an opportunity of inspecting a capital show of Pelargoniums in the Rycroft Nursery of Mr. H. J. JONES, whose indefatigable energy is almost as observable in the culture of this class of plants as in Chrysanthemums. A Chrysanthemum nursery, where no other plants are cultivated, must necessarily experience a considerable amount of dull or quiet time in each year; and so Begonias, decorative zonal, and Ivy-leaved Pelargoniums, besides many other plants,

have been added to the Rycroft collection. Several pieces of land have been acquired during the past year, and a fortnight ago premises were secured on the High Road, Lewisham, for the purpose of commencing a florist's business. But to revert to the Pelargoniums, it need hardly be said that they were thoroughly well grown, nor is it surprising that the immense number of varieties the collection embraces belong chiefly to the decorative class, for these are most popular. Show Pelargoniums have come to be regarded as plants for exhibition only, and the demand for them is a very limited one. The decorative varieties are of robust growth, exceedingly free in flowering; they produce large trusses of gay flowers that literally hide the plant itself from view; and, moreover, if a person understands the general treatment they require,

decidedly worthy commendation, and has a capital truss and bloom. The lower petals are pink, marked occasionally with crimson, and the two upper ones nearly covered with a rich velvety-crimson flame. Mrs. F. Walker has flowers of white shaded lilac-rose, and dark crimson blotches. Claude Bernard, flowers white and pink; Albert Pratt, rose-coloured, with dark crimson stripes and blotch; Eucharis, an almost white flower of sterling value, but possessing a pink spot or two upon each bloom; and Mrs. G. Gordon, pink and white, were all noteworthy. Mrs. W. Wright, Ladas, Royal Rose, and Lady Duff should also be mentioned. Looking through other houses where the zonal and Ivy-leaved Pelargoniums are, we were shown a novelty from a cross between Ivy-leaved Souvenir de Chas. Turner, and a white single-flowering zonal variety. This has

FIG. 155.—OAK PLANTED AT CHATSWORTH BY THE PRINCESS VICTORIA, IN 1832. (SEE P. 405.)

their cultivation is easy and inexpensive. But there are the Regal Pelargoniums, with semi-double blossoms, rather better if judged by the individual bloom than the single ones, but not quite so free as these, though they continue to throw trusses a longer time. These are fully as worth cultivation as are the decorative sorts. The plants were staged in one of Mr. JONES' large span-roofed houses, where the mass of bloom was overpowering in its abundance. The recent bright weather and hot sunshine was rapidly hurrying the flowers to maturity, and before these hues are read, the beauty of the show must have passed. It may be of interest to mention a few of the best varieties, but the selection must be a very exclusive one, and if the reason be asked, the reply is "Jubilee." Duchess of Portland is a new one, produces a large flower and fine frass, the ground colour of the flower is pale pink, with deep rosy blotch. Mrs. Graham is

been called Achievement. The flowers are large, semi-double, and salmon-pink, thus in point of colour being modified by its white-flowering parent.

YORK SHOW.—We learn with much concern that on the morning of the opening day a storm broke over the city of York, wrecking the exhibition, and causing irretrievable havoc among the horticultural exhibits of all kinds. Our correspondent, Mr. HATLEY WADDS, who was to have been one of the judges, sends us the following brief account of the catastrophe:—The best exhibition of Orchids, plants, flowers, and fruit ever brought together by the enterprising committee of the York Gala was destroyed by a furious gale this morning (Wednesday, 16th inst.), six large tents containing the exhibits of the best growers in the country were blown down one after the other, just as the judges were about to commence their

work. The destruction and damage to the beautiful plants and fruit was saddening to behold, and the scene was one not likely to be forgotten by those who witnessed it. The executive, as well as the exhibitors, whose productions have suffered so much injury will, I am sure, have the sympathy and support of everyone in the difficult situation in which they are placed. A meeting of the committee was held under the presidency of the Lord Mayor, and it was resolved that the exhibits should be removed, but that the gala so far as possible should proceed, the admission to the field to be reduced to 1s. before 6 o'clock,

"QUEEN'S TREES."

IN olden times, long before forestry was promoted to the rank of a science, Mary, the ill-fated Queen of Scots, was an assiduous planter. In most of the old Scottish domains may be seen a tree or trees, the planting of which is attributed to her. The tradition of which is true—but if so, the Queen's industry must have been remarkable, and the longevity of the trees noteworthy.

A word of caution may appropriately be given in this Jubilee year, when planting of this kind is likely to be done: first, to prepare the tree beforehand; second, to spare no pains in preparing the soil and planting the tree. It is needless to say that the tree selected should be one suitable to the climate, soil, and aspect. A handsome Beech or Oak is preferable to a Conifer, which may prove out of harmony with the surroundings, and speedily become shabby. There is no room for experiment in the planting of memorial trees, and for patriotic reasons some British tree—an Oak or a Scots Fir—should be chosen. On other occasions we may utilise the Douglas Fir, Lobbs' Thuya (= *T. plicata*, true), *Abies brachyphylla*, a *Nordmanniana*, *Tsuga Mertensiana*, evergreen Oaks, Turkey Oaks, and many others.

WINDSOR.

A Cedar planted on the slopes of Windsor Castle in 1840, very shortly after Her Majesty's marriage, is one of the earliest of which we have any record. It is a flourishing tree, and likely to excite the curiosity of our successors for generations to come.

There are many other commemorative trees planted by Her Majesty in the domains at Windsor, such as a Deodar Cedar previously figured by us, but of which we have no definite particulars as to date of planting, or dimensions, and of which we may therefore merely record the existence.

OSBORNE.

Abies Pinsapo, planted on the occasion of Her Majesty's birthday, on May 24, 1849, has now a circumference of 7 feet 9 inches at 1 foot from the ground, and is 45 feet in height (see fig. 157).

Cupressus macrocarpa (*Lambertiana*), planted near the Swiss Cottage on February 10, 1862, has a circumference of 6 feet 6 inches, and a height of about 60 feet.

Another plant of the same species, planted on the garden lawn on May 24, 1855, is about 35 feet high, and is very spreading.

A *Cryptomeria Lobbi* was planted on May 24, 1857; a *Sequoia gigantea* (*Wellingtonia*), on the same day in 1858; and a *Cupressus Lawsoniana* in 1860.

Abies grandis was planted in honour of the christening of H.R.H. Prince Emich, of Leiningen, on February 10, 1866; and *Abies Nordmanniana* on the same day in 1869; and *Cupressus* (*Retinospora*) *squarrosa* on the same day in 1871.

Thuja delabrata was planted by Her Majesty the Queen in memory of Emperor Napoleon III., on the day of his funeral, January 15, 1873.

A plant of *Abies lasiocarpa* is commemorative of the Silver Wedding-day of the Crown Prince and Princess of Germany, January 25, 1883.

Abies grandis, planted on Her Majesty's seventieth birthday in 1889, is one of the more recent commemorative trees that owe their present position to her hand.

Many of the above-mentioned trees have made but indifferent progress, and the *Cupressus macrocarpa* seems to thrive best of any.

CHATSWORTH.

At Chatsworth is an Oak with an interesting history (see fig. 155, p. 404). It was planted in 1832 by the Princess Victoria, when visiting Chatsworth with the Duchess of Kent. It is a healthy tree, planted in a hollow on the north side of the West Terrace, not far from the great bountain; and close by is a Spanish Chestnut planted by the Duchess of Kent, and at a later period a Sycamore by the Prince Consort.

FIG. 156.—*TRACHYCARPUS* (*CHAMAEROPS*) *FORTUNEI*, IN THE QUEEN'S GARDEN, AT OSBORNE.
(SEE P. 296.)

and *6d.* afterwards, these being half-prices. Posters were also issued announcing that no flower-show would be held, and the committee thus were faithful to the public, who were, however, informed that they would be admitted at half-price. The show of flowers is, of course, to the visitors on the first day the chief attraction of the gala, but there are several other items in the varied programme which afford a large amount of interest.

PUBLICATIONS RECEIVED.—*The Fertility of the Land*, by J. P. ROBERTS (MACMILLAN & CO.).—*Clay's Successful Gardening*.—*The Yew Trees of Great Britain*, by JOHN LOWE, M.D. (MACMILLAN & CO.).—*First Report of the Women Experimental Fruit Farm*.—*Journal of the Kew Guild*.

In Mary's time there was no *Gardeners' Chronicle* to record these matters, but the occurrence of the sixtieth anniversary of Her Majesty's auspicious reign induced us to collect some authentic particulars relating to trees known to have been planted by the Queen. Many of these are in Scotland, and commemorate happy days passed north of the Tweed. To many of the gardeners and foresters we are under obligations, and in particular to Mr. Malcolm Dunn, who has greatly helped us in our investigations. We do not suppose the list is in any way complete, but in any case it is interesting to loyal Britons, and not without use to foresters.

TAYMOUTH.

On the occasion of their visit to the Marquis of Breadalbane in September, 1842, the Queen and the Prince each planted two trees, a Scots Pine and an Oak. The fact is mentioned under date of September 10, 1842, in *Leaves from the Journal of our Life in the Highlands*, small edition, p. 19: "Each of us planted two trees, a Fir and an Oak."

It is interesting to have the dimensions of these trees taken on April 17, 1897, and obligingly communicated to us by W. Dunn, Esq., the factor to the Breadalbane estate:—

THE QUEEN'S TREES.

Oak.—The length of bole to fork is 13½ feet; it then branches off in two limbs. The circumference at ground 6 feet 10 inches; at the height of 5 feet it measures 6 feet 2 inches; total height from the ground to the top of the highest branch 49 feet; the spread of branches 44 feet.

Scots Fir.—Circumference at ground is 7 feet 6 inches; at 5 feet up 6 feet 3 inches, from ground to first branches 9 feet, total height 55 feet, spread of branches 23 feet.

PRINCE ALBERT'S TREES.

Oak.—Length of bole to fork is 8 feet 3 inches, at this height it branches off into 4 branches, one of which was broken off by a snow-storm a good many years ago; girth at ground 7 feet 3 inches, at 5 feet up 5 feet 9 inches, total height 45 feet, spread of branches 54 feet. This tree was a good deal rent in the bole at the time the branch was broken off.

Scots Fir.—Circumference at surface 6 feet 5 inches, at 5 feet up 5 feet 4 inches, from ground to first branches 9 feet, spread of branches 33 feet, total height 40 feet. The above measurements were taken on April 17, 1897. *Wm. Dunn, Meins of Kenmore.*

DRUMMOND CASTLE.

A few days after leaving Taymouth in 1842 the Royal party visited Drummond Castle, of the garden of which Her Majesty remarks that "it is really very fine with terraces like an old French garden." (*Leaves*, &c., p. 22) see *Gardeners' Chronicle*, May 26, 1877. Here also the Queen planted a purple Beech. This tree, as we learn from Mr. Robb, is now about 60 feet in height with 9 feet of clear stem, and 7 feet in circumference at 3 feet from the root.

BLAIR ATHOLE.

In September, 1844, Her Majesty records her stay in this picturesque spot, and previously to leaving "the dear hills" on October 1, she planted two Oaks, of which the present dimensions according to Mr. Keir are—

No. 1.—Entire height of tree 61 feet 6 inches spread of branches 26 feet 6 inches, length of clear bole 15 feet 6 inches, girth at 3 feet up 5 feet ½ inch, girth at 15 feet up 4 feet 2½ inches. No. 2.—Entire height of tree 49 feet 3 inches, spread of branches 48 feet, length of clear bole 11 feet 3 inches, girth at 3 feet up 5 feet ½ inches, girth at 11 feet up 4 feet 8 inches. The two trees are the common British Oak, growing side by side on light loam, sub-soil gravel resting on lime.

ARDVERIKIE (INTERNESS).

At this place, in 1847, the Queen planted a Scots Fir and the Prince a Larch, immediately to the west of the house. The trees go by the name of the Queen's and of the Prince Consort's trees. The Queen mentions her visit to the place, August 21, 1847:—"The country is very fine, but the weather most dreadful." *Leaves*, p. 57. Unfortunately, the trees were planted on a spot with very light soil on a hard pan; besides that, from 1850, when the late Marquess of Aberdeen ceased to be the tenant of Ardverikie, until 1870, when the forest came into the possession of the present proprietor, Sir John W. Ramsden, Bart., the place was much neglected. The trees were left unprotected,

and were seriously injured by cattle and deer. Since 1870, every possible care has been taken of the trees, and fresh soil has been supplied to their roots; and they have, in consequence, made fair progress during the last twenty-seven years, though it is to be feared they will never entirely recover from the injuries received during the previous twenty years of neglect. Still, they look healthy, and are growing side by side, and are likely to keep growing for generations to come. The size of the trees does not correspond with the number of years since they were planted, owing to the causes I have mentioned. The Scots Fir at 5 feet from the ground has a girth of 3 feet 7 inches, its height is approximately 40 feet. The Larch is 47 feet in height. *Angus Macpherson.*

HADDO HOUSE.

Visitors to the Conifer Congress will remember the splendid examples of tree-growth sent from that estate. A Wellingtonia, planted by Her Majesty in October, 1857, has now the following dimensions:—

Sequoia gigantea (Wellingtonia), planted at Haddo House by Queen Victoria, October, 1857. Height of tree, 60 feet; girth of stem 1 foot from ground, 11 feet 6 inches; at 5 feet from ground, 9 feet; circumference of branches at ground, 75 feet. The tree is healthy and symmetrical, and stands about 50 yards to the east of Haddo House. It has a granite tablet in front with the inscription, "Planted by Queen Victoria in 1857." Another Wellingtonia was planted at the same time by the Prince Consort. The dimensions of it are almost identical with the Queen's tree. It has also a granite tablet in front stating that it was "planted by the Prince Consort in 1857." *J. Forrest, The Gardens, Haddo House.*

BALMORAL (ABERDEENSHIRE).

Mr. Michie obligingly forwards us the following tabular statement of trees planted by Her Majesty the Queen (personally) on the estate of Balmoral:—

Name of Tree.	Date of Planting.	Occasion when Planted.	Approximate Size.		Remarks.
			Height.	Girth above spread of roots.	
<i>Acer Pseudo-Platanus</i>	10th May, 1862	Not stated.	Ft. Ins. 15 0	Ft. Ins. 2 1	
<i>Acer Pseudo-Platanus</i>	10th May, 1862	For H.R.H. the Prince Consort.	20 0	2 6	These two <i>Sycamores</i> have been planted in very poor gravelly soil, and are exposed to northern hill storms. They bear a gaunt appearance.
<i>Abies Albertiana</i> (<i>Tsuga Mertensiana</i>)	4th Oct., 1865	Not stated.	37 0	4 6	Quite healthy and clothed to the ground.
<i>Abies nobilis</i>	24th May, 1839	On 50th anniversary of Birthday.	35 0	5 3	Do.
<i>Abies nobilis</i>	20th Sept., 1873	In recollection of Princess Hohenzollern.	14 0	2 7	Do.
<i>Abies nobilis</i>	26th May, 1876	In recollection of the infant Prince Harold.	22 0	3 2	Young shoots frequently cut back by summer frosts.
<i>Cupressus Lawsoniana</i>	20th June, 1877	In commemoration of 40th year of Accession.	12 6	...	This tree takes shrub form. Spread of branches, 30 feet circumference.
<i>Abies nobilis</i>	24th May, 1879	On 60th anniversary of Birthday.	21 6	2 7	Do.
<i>Abies nobilis</i>	24th Nov., 1879	Not stated.	25 0	3 8	Frequently nipped by summer frosts.
<i>Ficus Cerebra</i>	16th June, 1887	For Jubilee Day, 21st June, 1887.	13 0	1 4	Healthy and doing well.
<i>Ficus Cerebra</i>	20th May, 1880	On 70th anniversary of Birthday.	8 6	1 0	Do.
Weeping Willow mitreok	Kil- 19th June, 1880	In memory of the Dowager Marchioness of Ely.	6 0	...	Do.

This tree was not planted by the Queen herself, she being at the time at Windsor.

The soil in which all of them are planted is poor and gravelly, while the altitude is about 900 feet above sea level, and exposure north and west. Of all exotic conifers I find the *Ficus Cerebra* thrives best

under the above conditions. It matures its young wood and seeds, from which I have raised quantities of plants. *John Michie.*

DUNKELD.

In the pleasure-grounds at Dunkeld is a specimen of *Cedrus atlantica*, planted by the Queen, October 13, 1865; its height is now 32 feet, circumference at 1 foot from ground 5 feet 4 inches, as reported by Mr. Fairgrieve.

FLOORS CASTLE (ROXBURGHSHIRE).

At Floors there is a Wellingtonia (*Sequoia gigantea*) planted by Her Majesty in August, 1867, the present dimensions of which, according to Mr. Street, are height 57 feet; 10 feet in circumference at 1 foot from the ground; 6 feet in girth at 5 feet from the ground; the branches measure 12 feet from the stem.

INVERARY CASTLE (ARGYLL).

Here are a Silver Fir and a Lebanon Cedar, both planted on the same date. Mr. Taylor obligingly furnishes the following particulars:—

Silver Fir planted by the Queen, September 27, 1875, height about 33 feet; girth 5 feet up, 2 feet 6½ inches; diameter of spread of branches, 19 feet. The tree is in very good health.

Cedar of Lebanon, planted on the same date as the Silver Fir. Height 10 feet; girth 2 feet up, 1 foot 6 inches; diameter of spread of branches, 12 feet. This tree has had the misfortune to lose its leader often, therefore it is just a mere bush, but in rather better health than it was, and making more growth. *G. Taylor.*

BROXMOUTH PARK (HADDINGTON).

A Deodar (*Cedrus Deodar*) was planted here by the Queen on the 26th August, 1878, and did well till the top was broken off by a strong north-easterly gale; but Mr. Taylor informs us that it is growing away quite freely, its height is now 15 feet, diameter of branches 15 feet, girth of the stem at 5 feet from the ground is 22 inches.

EDINBURGH.

A group of four trees was planted by members of the Royal Family in the grounds in front of the main entrance to the International Exhibition, held

in the West Meadows Park, at Edinburgh, in 1886. The central tree of the group, a Scots Elm, was, according to the inscription on the label at the foot of the tree—

“Planted in the Name
and Presence of
H. M. Queen Victoria,
By the Marquis of Lathian,
19th August, 1886.”

The Queen's tree is doing fairly well in the smoke-laden atmosphere, and gives promise of growing into a nice specimen in course of time. It is about 10 feet in height, with a clean stem of about 5 feet, and a nicely branching head; the stem girth being 9 inches at 3 feet from the ground.

On the 14th of October the Prince and Princess of Wales each planted a “Plane-tree” (*anglicae* Sycamore), in the group, both of which are about 12 feet high and thriving well, considering their position and the vitiated atmosphere of the place.

Prince Albert Victor opened the exhibition on the 6th of May, 1886, and on the same day planted the first tree of the group, an English Elm, which is now about 10 feet high, on a clean stem of about 5 feet and thriving fairly well. *Melcoln Dixon, May 26, 1887.*

ORCHID NOTES AND GLEANINGS.

HABENARIA ELLIOTTI, A. Rolfe.

HABENARIAS, with the exception of a very few species, are not in fashion, and are not in great favour among horticulturists. Even the gardeners of botanical institutes are not fond of them, owing to the difficulties real, or perhaps only assumed, that are found in growing them. In consequence of this, the fact of flowering any *Habenaria* is very seldom recorded in the *Gardeners' Chronicle*, or the botanical periodicals. To-day we are surprised by the flowering of a species of quite recent date, it only having been known to botanists for a space of about ten years. The plant was discovered in Madagascar by Mr. F. Scott Elliot; specimens of the plant were described and named by Mr. R. A. Rolfe of Kew; and afterwards, a description founded upon these materials, was published in the *Monograph of Habenaria* in Engler's *Jahrbuchern*, 1891, p. 70. The plant was afterwards collected by our late friend, Mr. Johannes Braun, who died at Antananarivo. He succeeded in digging out some specimens without injuring the very tender roots; the package was then sent to Europe, but before it arrived the unfortunate collector had died. The whole stock was then purchased by Mr. Wendland, of Herrehausen, and under his skilful treatment many of the plants were brought to perfection and flowering.

The plant is no great beauty after all, as *Habenarias* seldom are, but the spike of about 30 cm. (rather less than 1 foot) in length, bearing about 70 flowers, all opening at one time, it has a nice effect. The foliage is luxuriant; there are ten to twelve strong, bright green, lanceolate leaves around the thick, strong stem, and a group of about four to five specimens flowering at the same time, as we learn that they do to-day at Herrehausen, is, at any rate, by no means inferior to a bunch of our European *Platanthera bifolia* or *P. chlorantha*, two species with which *Habenaria Elliotti* agrees also in the aroma of the flowers. The flowers are of the very peculiar structure characteristic of the true *Habenaria*, i.e., three sepals of a green colour, two petals deeply cleft, a lip also cleft to the very base into three narrow linear lobes, and lastly a long, thin spur; all of this, and the thin whitish leaflets, eight on each flower, twisted and whorled in the whole length of the spike, afford an object as striking as those we are accustomed to see in *Bolbophyllum* for instance, with movable lips and hairs, or in the grotesque *Catantenus*. It is not for their beauty that the *Catantenus* and many other plants of this kind are admired; but for the wonderful apparatus of the flowers for securing fertilisation by insect agency. If we admit this proposition, we must also admit

that very often a greater charm is to be expected from inconspicuous flowers of those plants which at the present possess botanical interest only, than from the most splendid *Lilias* or *Cattleyas*, the interior construction of which is a comparatively simple. The plant in question, on arrival in Europe, was very weak, but it has been brought to a healthy and vigorous condition, and flowered this year for the first time. I believe the time is not far distant when the old dislike of terrestrial Orchids will disappear, and that they will be more generally cultivated. Gardeners may object that none of them is fit to become a trade Orchid, or one suitable for table decorations; but *Mastcellias*, for instance, in the majority of species, are in favour with amateur cultivators, notwithstanding that only a few of them are what are called “ornamental plants.” At any rate, botanists will mark in their almanacks the day when they had the opportunity of studying living specimens of a plant known only until this day by dried specimens; and gardeners will, perhaps,

FIG. 157.—*HABENARIA ELLIOTTI*.
(Planted at Osborne by H. M. The Queen on the anniversary of her Birthday, May 24, 1887. Present height, 45 feet.)
(See p. 405.)

look to the future with some hopes of having interesting plants in cultivation when the species now so much grown are no longer in fashion. *F. Kronlin.*

HOME CORRESPONDENCE.

ENGLAND'S FLORAL EMBLEM FOR JUBILEE DAY.—Since the receipt of a letter from the Very Rev. the Dean of Rochester, Dr. Hole, sympathising with my suggestion that the Rose should be worn by everyone on Jubilee Day, hundreds of communications have reached me to the same effect. This is “the month of Roses,” and after the refreshing rains we have recently had, there will be an abundance of Roses for the eventful day. Their beauty and fragrance will be very welcome. In the times of the early Kings of France, *Chambers's Book of Days* informs us “The Parliament, placed between Royalty and the Church, formed one of the great powers of the State. The Kings felt a real esteem and respect for the judiciary body, and regularly attended its sittings; besides, it was not always stationary in Paris, but made an annual

tour, when Princes and Princesses of Royal blood were accustomed to follow its laborious peregrinations, and thus add to the brilliance and pomp of its meetings. It was in 1227, during one of these judicial pilgrimages, that the custom called “The Tribute of Roses” was founded, one of the most charming of which the Parliamentary annals speak. The ceremony was created by a woman and for a woman, by a powerful and illustrious queen for the wise and lovely daughter of the first President of the first Parliament of Paris, and possesses at the same time the majesty of all that comes from a throne and the grace of all that comes from a woman.” It would be most appropriate that in all future years, a day in June should be set apart in this country as a national holiday and “Commemoration day” of our Queen's Diamond Jubilee, when “The Tribute of Roses” might form one of the leading features of the occasion, and be popularly known as the “Royal Rose Day.” *Ellis Leves, Colwyn Bay, June 15.*

THE RENAISSANCE OF THE HOLLYHOCK.—Your correspondent, “R. M.,” may be assured that I am well aware of the subtlety and power of the dangerous enemy with which we have to contend. Neither have I much hope of ever getting entirely free of the disease that has hid low our Hollyhocks. But I think we may, and can, by means of careful treatment and judicious cultivation, invigorate the constitution of the Hollyhock to such an extent that the Puccinia will not penetrate the tissues, but will fall harmlessly from the plants. This is just what is being done with the equally if not more insidious Potato disease. Messrs. Findley, Sutton, and others, have furnished their seedlings with a vital force and vigour that resist the disease, while also in the process doubling or trebling the average yield of less than 7 tons per acre, while also improving the quality. Why should not “R. M.,” and other Hollyhock growers, and all of us, go and do likewise with these plants, and possess ourselves in the hope that we may yet have to heighten our step-ladders, and strengthen our stakes for our old favourites? One point of culture was much more carefully attended to by the older gardeners than by those of the present day, namely, the early and severe thinning of the flower-buds, especially on the doubles, thus allowing each to develop to its full extent without trussing. I am pleased also to verify your correspondent's remarks about the superior quality of Scottish Violas and Pansies, and the products of the growers of forty or more years ago. But the drought in the south and east of England is against Violas and Pansies reaching to the high standard of the north. *D. T. E.*

EARLY-FLOWERING STRAWBERRIES.—Would “D. T. F.” be surprised to learn that Strawberry-plants were in bloom in the south of London nearly a month earlier than were Mr. Curmeil's in Scotland? Then why in extolling the leaf habits of that rarer's new varieties, seem to disparage the usefulness of such a fine variety as Royal Sovereign, with respect to the strong leafage, of which not one of the several thousands of growers, who now pronounce it to be the finest recent acquisition to Strawberries, make complaint. As to its cropping qualities, it is a libel to hint the plants have more leaves than fruits. As to habit, if that be so great a feature in pot-plants, Veitch's Perfection—that superbly-favoured new variety from British Queen and Waterloo—should satisfy the most exacting. The foliage is medium and curled, the blooms very abundant. *A.*

JANÆA HELDREICHI.—Mr. Arthur K. Bolley has had the fortunate idea and opportunity to afford to this very capricious plant just the conditions under which it grows in its home. Solid oblique rocks are covered by mossy hillocks, having underneath 2 to 3 inches of vegetable mould, and between the rock and the underside of these bolsters, humidity and water works its way down during a great part of the year. In winter they are deeply covered by snow, which disappears late in the spring, and in summer they never get completely dry, the small canon or creek always having moist air. They grow as well on the shady as on the sunny side, but the plants on the shady side, though bigger, are less floriferous. *Mrs. Leichlin, Baden-Baden.*

REDUCING THE HEIGHT OF TALL TREEFERNS.—The process given in your last issue is clumsy, unsightly, and unnecessary. We have a large *Alsophila Moorei*, which grew too tall for our conservatory, many years ago. It is planted in a box 20 inches deep, and every second year we take it out, and cut about 12 inches off the bottom with a sharp spade, dropping it to the bottom of the box,

and filling up with fresh soil. There is no check visible after this severe treatment, and it grows as luxuriantly as ever. In its native country this Fern may be cut off at any part of the stem, and the upper part stuck in the ground, where it will root at once, and grow on as well as if it had not been touched. This can readily be understood, the stem being simply covered with a mass of roots already formed, which grow with the slightest encouragement. *Thos. Fletcher, Grappenhall, Cheshire.*

OLEARIA STELLULATA.—Should this latest addition to these charming Olive-like shrubs, so well-gated by Messrs. Veitch at the Temple Show, and illustrated on p. 351 of the *Gardeners' Chronicle* recently, prove as easily grown, floriferous, and hardy as the *Olearia Haasti*, it will, doubtless, have a great and popular future career before it in our gardens. It will therefore prove of special interest for intending planters to know if the plants exhibited in full flower in May were from the open ground, or had been at all forwarded in a greenhouse. Having recently seen several specimens of the pretty New Zealand *Olearia Haasti* in excellent condition of shelter and exposure, specially in such bleak gardens as that at Castleroy, Broughty Ferry, it would be interesting to learn whether the new comer is likely to prove equally hardy. Also, whether anyone has proved any of the older species as hardy and as useful as *O. Haasti*? If not, not a few cultivators have found such species as *O. Gunniana* very useful for the cool greenhouse; the clothing of warm walls, or furnishing sheltered corners with a mere fringe of bracken fronds thrown over it in severe weather. *D. T. F.*

MELON WINDSOR CASTLE.—This fine variety is this season better than usual, the fruit being larger and finer flavoured. Of four fruits on one plant, the smallest weighed 8½ lb., and the largest 10½ lb. This will show that a large amount of nourishment is required to keep fruiting plants going. Of all the green-fleshed varieties that have come under my notice, none has surpassed this for size or good quality. It is, however, not an early-fruiter, and when grown in the open of mixed varieties, it should be planted at one end by itself, so that it may receive the proper kind of cultivation till the fruits ripen. When mixed with early varieties, it or they suffer, as it is not possible to give to each the required treatment. *H. C. P.*

COMMEMORATIVE TREES.—I hope that those who are thinking of planting such trees will choose such as are likely to be "trees of the future." It is deplorable to see so many wretched specimens of commemorative trees about the country, simply because the kinds have been ill-chosen. It seems to me that gardeners are asked to get the trees, and they get in most cases Conifers of doubtful suitability for this country, and certainly Lot trees that will mark time a century hence. Out of a large group of "Royal" trees I saw the other day the only thriving trees were Cedar of Lebanon, Abies brachyphylla, and Picea pungens; the rest were Abies nobilis (grafted and "gouty"), Nordmann's Fir, Cryptomeria, Deodar, Douglas Fir, and Retinospora! all merely existing in the cold days of the Midlands. Unfortunately the planting of these "Royal" and other commemorative trees takes place generally in the summer, but there are at least a dozen Conifers besides evergreen Oaks, &c., that are beyond suspicion. But the real commemorative trees are the large deciduous trees about which there is no doubt that generations to come will be able to sit under their shadow at the end of the next century. Better plant one acorn of an English Oak than a whole grove of aliens of unproved adaptability to the climate of these islands. *W. Goldring.*

THE RECENT TEMPLE SHOW.—I cannot help thinking that in making the awards at the Temple Show, a great want of consistency was shown in several of them. For instance, Silver Cups, it would seem, were awarded to mere quantity quite apart from quality—which is a very questionable precedent to set up. Take the case of a collection of herbaceous plants shown by one firm. If one half of this collection had been placed under the tables instead of on the top of them, the show would not have been one whit the poorer for the loss of it; and many of the bunches of faded dull-coloured Iris might have been omitted with decided advantage. What effect was gained by the huddling up together of weedy-looking bunches of common garden-flowers which everyone knows, and which were neither instructive nor interesting? Then there were the poor bunches of Cactus and decorative Dahlias, unaturally forced into bloom,

and forming an indifferent representation of good varieties, actually discounting their value. Who wants Grand Dahlias in May? Then a huge panel of sprays of Violets, which quickly fade, had nothing about it novel or striking, and yet a Silver Cup was awarded to each of these exhibitors, placing them in the front rank of excellence, and on a level with Turner's Roses, and Mr. Melrose's magnificent collection of fruit. A group of new Holland plants from Messrs. Balchin & Sons of Hassocks, was degraded by being relegated to the fifth class of value. Surely those who gave this unique and admirably grown and bloomed collection, the award of a Silver-gilt Bankian Medal, the lowest in value of the Silver-gilt Medals of the society, could have known but very little about such plants. The very smallest among them was relatively a perfect specimen, and there was nothing probably which had had less than three years' culture. Fancy placing such admirably grown specimens of *Darwinia tulipifera* and *Erica Spenceriana* on a level with cockney rockwork, faded border flowers, and immature Cactus Dahlias the former requires the greatest skill to cultivate, the latter none at all. I indulge in this growl with considerable reluctance, but it is forced from me by what I consider glaring inconsistency in the awards made at the Temple Show. *A Fellow.*

PLANTS OF THE QUEEN.—To the list of plants named after Her Majesty the Queen, at p. 334, I should like to add *Cineraria The Queen*, and *Cucumber Empress of India*. Both were raised at the Exeter Nursery, and distributed early in the eighties by the late Dr. Wm. Robt. Woodman, when trading as Leachway, Finsbury, Co. The former was a magnificent variety, rich purplish crimson, with white centre, of great substance, the individual flowers as large as crown pieces, and the variety was chosen from a new strain of *Cinerarias* known as the Wonder of the West strain by the doctor, and named by him. The *Cucumber Empress of India* was a fine white-spined variety of use for summer cultivation. The fruits averaged 20 to 24 inches in length, and the variety was awarded a Certificate by the Royal Western Horticultural Society, and it became popular in west country gardens. *W. Napper, Royal Ashburham Park Nursery, Chelsea.*

DARWIN TULIPS.—The correspondent who started the theory that this race of fine Tulips was raised by Mr. Krelage, did so without the slightest foundation or authority. The history is described at length by me in the *Gardeners' Chronicle* of April 7, 1891, my facts having been obtained direct from my excellent friend, Mr. Krelage. These Tulips are of Flemish origin, and originated from seeds sown between 1560 and 1572, from the best breeders and brimex strains. The entire stock was bought from the raiser by Mr. Krelage, and, when the stock had been considerably multiplied, by him, distributed. If writers would only take a little more care to verify their "facts" before making reckless statements, they would cease to propagate a considerable number of absurd rumours. *W. Roberts, Carlton Villa, Kileas Avenue, Clapham, S.W.*

—Is not "F. W. B.'s" criticism on these Tulips, at p. 372, a little captious, seeing that the error in my previous note on which he comments was in making Mr. Krelage the raiser, when I should have said that he put them into commerce. But "F. W. B." with that habit which is getting rather unpleasantly characteristic of the modern writer, whilst giving utterance to a growl in the *Gardeners' Chronicle*, at once rushes into the columns of a contemporary to show my appalling ignorance. Does it not seem as if ordinary courtesy should have led him to have embodied his explanatory remarks in the note sent to the *Gardeners' Chronicle* rather than to have made them the vehicle of a note in the pages of a contemporary, the readers of which must have wondered at what "F. W. B." was driving. My object in penning the note was to dispel a very common illusion, that these Tulips were so named because raised by Mr. Darwin, whereas they are merely so named out of compliment to the great naturalist. It may be right to refer to them as breeder Tulips, although they rarely break; but call them by what name you may, they are singularly constant in their self-colours, and are also as wonderfully beautiful. It has been said that they are in the majority of dull blues. Surely that is an error. As seen at Long Ditton recently, they were generally as brilliant as beautiful. As to their not being "evolved" if not, then are they all natural species? Certainly

not. Every garden variety has been more or less "evolved." *X.*

ROSES OF THE VICTORIAN ERA.—I was surprised to find that the splendid and well-known results of the efforts of Messrs. William Paul & Son, of Waltham Cross, and Messrs. Paul & Son, of Cheshunt, were almost entirely ignored in the article at p. 377. I will give a list of the more notable varieties sent out by the two firms mentioned above, and I opine that a glance at this list will tend to prove that "Wild Rose" has omitted to mention several sterling varieties of the Victorian Era that are met with not only in every exhibition-box, but what is far better, in every garden where Roses are grown for their decorative qualities. Messrs. William Paul & Son, of Waltham Cross, have enriched our collection of Roses with such superb varieties as:—

Beauty of Waltham.	Lord Mearns.
Black Prince.	Magna Charta.
Charles Lumb.	Marchioness of Lorne.
Cllo.	Medea.
Corina.	Pink Rover.
Crimson Glove (Moss).	Pride of Waltham.
Crimson Queen.	Queen Mab.
Geona France.	Queen of Queens.
Duchess of Albany.	Salamander.
Duke of Albany.	Shippo.
Duke of York.	Spenser.
Ella Gordon.	Star of Waltham.
Empress Alexandra of Russia.	Sulph.
Eucharist.	Waltham Climber.
Lord Bacon.	White Lady.
Little Gem.	And many others.

In addition, this firm has introduced varieties of other raisers, such as Danmark, Duchess of Bedford, Countess of Rosebery, &c. Among the many beautiful varieties sent out by Messrs. Paul & Son, of Cheshunt, we find such names as—

Carnine Pillar.	Glorie of Cheshunt.
Charles Garter.	Madame Norman Neruda.
Cheshunt Hybrid.	Mrs. Paul.
Dowager Duchess of Marlborough.	Paul's Single White.
Duke of Connaught.	Queen of Autumn.
Duke of Teck.	Sultan of Zambiar, &c.
	St. Reynolds Hotel.

"Wild Rose" says: "It seems as if France has done all she can for us." Now I would be the last to depreciate the grand efforts of my own countrymen, and I believe they now take the lead in the van of progress; but I should not like to make such a statement as "Wild Rose" makes. If he had seen, as I have seen, some of the beautiful novelties emanating from our Gallic neighbours this season and last season, I think he would not have made such a sweeping assertion. *W. Estlin, Waltham Cross.*

CELEBRATING THE JUBILEE.—There are many different ways of marking the Diamond Jubilee among trading firms and by private employers, and I would like to let your readers know what is the Hon. E. W. B. Portman's manner of doing this. The family is going from home, and instructions have been given that all employees on his Hestercombe estate, indoors and out, are to be paid one week's wages as a gift, which has been done. I trust that many other employers of labour may mark the joyous event by doing likewise. *A. J. Ken.*

WORTHING PUBLIC PARK.

SITUATED in the north-east of the town, this park has been in existence for some years. It was not always particularly attractive from a horticultural standpoint, but thanks to the present superintendent, Mr. C. Evans, it is now a charming public garden. Taken as a whole, it is pleasantly diversified, embracing within its limits a fine level cricket-ground, some artificially raised mounds, a good tennis-court, open and shady walks, and a shapely little lake with its islands, rustic bridge, and other picturesque accessories. Surrounding the park we have a wealth of handsome foliage, on well-grown Sycamores, Elms, Limes, Ash, Holm Oak, and other trees. Entering the park by the main gate in Park Road, we saw recently a long curved bed, bordering the main path, containing some 200 to 300 Wallflowers of a fine dark crimson variety, and a delicate white Alyssum (Madwort) make up a good border, while immediately succeeding this there was a grand show of Cleveland blue Pansies. On our right, opposite this border, we noticed a heart-shaped bed surrounding a giant *Enonymus*. Here a border of Thrift was succeeded by masses of delicately tinted *Aubretia*, Pansies, Arabis, Tulips, and Wallflowers.

Taking the path to our right, we were on one side

a circular lawn, surrounded by Horse-Chestnuts and Limes, dotted here and there with well-trimmed Hawthorns. On our left, an untidy waste has been converted into a most tastefully laid-out garden. A shelter seat—not of any intrinsic beauty—divides two small grass plots. In the centre of the first, we observe three circular tangential beds. The outer ones have Yuccas in the centre, the central bed is crowned with a fine specimen of the garden Eucynurus. All three beds were rich in blossom; they were edged with the prolific Longfellow Daisy, while Parrot Tulips and choice mixed Violas were ranged around in concentric rings. Two

dwarf silver Pelargoniums filled in with Fuchsias Mrs. Masters and Rose of Castile, with tuberous and fibrous-rooted Begonias. The central bed has exceptionally fine specimens of Fuchsias, Abutilon Thompsoni, and Artemisia, with a carpet of Mesembryanthemum. We were now close to the lake, round whose borders we observed some fine Bamboos, Eulalia, Gunnera, Lombardy Poplars, and Pampas-grass. The little islands are bordered with masses of yellow Iris. A fine cricket-ground occupies the centre of the park, and on its north side is a pleasant terrace mount. The southern slope of the mount is bedecked with Eucynurus, Roses, dwarf Laburum,

ANTIGUA.

Messrs. F. Watts and F. R. Shepherd have published the results of their experiments upon the Sugar-cane, with a view to ascertain its natural requirements. Summarising, it would appear that, for plant-cane under these conditions potash is the manurial constituent having the most marked effect; that nitrogen has a slight, but not very marked, beneficial effect; and that phosphates decrease the yield. The results obtained by this use of phosphates are very different from what was expected, for the soils on which the experiments have been conducted are remarkably deficient in phosphates.

GRENADA.

Zephyranthes tubispatha, Herbert. — During the months of April and May one may notice that the dry unsightly open spaces about the town of St. George are looking quite transformed with the glory of the above-named plant. At the Botanic Garden it covers ground where turf refuses to grow, and is especially useful in hiding the soil along the edge of walks, though it grows, too, among the turf. In this way we plant thickly, and so have at the flowering season a large number of flowers open at the same time. Within the past week (May 3), when in town, I noticed thousands of this *Zephyranthes* in flower, growing evidently where they had been self-sown, and had never received care or attention. The upper portion of the flower is a pure white, the lower part green, and, unlike the Snowdrop, to which it may be likened in its habit of growth, the flower-tube stands nearly erect. In colour the leaves are a shiny green, some 6 to 9 inches long, narrow, and not more than a quarter of an inch wide. The flower stem is about the same length.

GRECOPIA PALMATA, W.

The leaves of this tree are remarkable not only for their large size, but also for the way in which they roll up into a sort of ball after falling from the tree, and are at this stage blown about by the wind. In a hilly and mountainous country, like Grenada, where everybody must ride on horseback to get about the colony, it not unfrequently happens that horses are startled by the rustling of these dried leaves as they lie on the ground, or when running along in front of the wind.

Locally, the tree is known as the Bois Canot. From its long hollow leaf stalks boys manipulate bird cages. These leaf stalks are 30 inches in length, and their blade or leafy portion about the same number of inches across, measured either way. This refers to young plants such as would be of use among stove collections of ornamental foliage plants. The leaves are alternate, ten to twelve-lobed, and the stem from where they grow has a ring plainly visible out-side, which indicates where the partitions of the stem are. In colour they are a dark green above, and nearly white below, with the ribs of the lobes prominent underneath, each graduating to a common centre, where they unite with the top of the leaf-stalk. The whole plant is clothed with small and rather stiffly pointed hairs. The stem is hollow, and jointed like a Bamboo, and the interior lined with a white mealy substance. In the older growth the wood becomes partly solid, but in the young soft stems there is little other than large hollow spaces. The tree is common in the island. When it grows into tree-like dimensions, its habit is to throw out roots which hold the trunk several feet above the ground. In windy weather, when the leaves are wafted to and fro by the wind, and before they drop, their appearance is very effective, due to the silvery colour of the under side brought to view. The leaves, after they have fallen, leave behind a large scar upon the trunk. Ants sometimes make a home of the hollow stems. W. E. Broadway, Grenada.

FIG. 158.—ORANGE TREE IN FRUIT, GROWING AGAINST A WALL IN THE KITCHEN GARDEN AT OSBORNE. (SEE P. 398.)

circular beds beyond the shelter contained English Irises, Peonies, Golden Viola, White Viola "Countess of Hopetoun," Spanish Iris, and other choice plants. The border between these lawns and the south wall is rich in herbaceous plants, including Genista, Cupressus, Yews, Box, Arbutus, Sweet Briar, Viburnum Tinus, Broom, Spirea, Holm Oak, white and purple-flowering Currants, Laburum, Sea Buckhorn, Sumach, Berberis Darwini, B. dulcis, Kalmia, Weigela, and very fine specimens of Escallonia nacrathia.

Crossing a very charming lawn, and taking the path beside the drinking fountain, we come to a smaller lawn, with a fine bed of herbaceous plants on the east side. In the middle of this lawn we noticed a very attractive bed, consisting of eight outer divisions surrounding an oval centre. The outer edging is of Viola Bullion, the second rows consisting of

Osmothus, Prunus Pissardi, and yellow and white Broom. The beds around the tennis-court were conspicuous for their wealth of foliage and blossom.

COLONIAL NOTES.

TRINIDAD.

We have recently received the *Bulletin of Miscellaneous Information* from the Royal Botanic Gardens, Trinidad, and note among its contents, papers on selection of seedling Sugar-canes, *Grevillea robusta*, *Isotoma longiflora*, Utilization of the Bamboo, *Cinnamomum camphora*, shade trees, and the Bergamot Orange; as well as shorter notes upon subjects of interest.

VEGETABLES.

LATE BROCCOLI.

REFERRING again to this subject, and the time of sowing, there is no doubt that seeds are often sown much too early for obtaining the best results so far

as a late supply is concerned. From the second week in May to the first week in June will be found quite early enough in the south and home counties for sowing the late varieties. My plan is to transplant direct from the seed-bed to the quarter to be devoted to Broccoli; and if sown early, plants are also drawn up spindly before ground can be spared for the crop. Early planting is not desirable, and although often advised, I always avoid planting on rich ground, medium-sized sturdy plants being always better able to pass through a severe winter. A plot that has been cleared of Strawberries or Peas is often used, the ground not being dug over, but simply hoed and cleaned, drilks being drawn with the hoe, or chopped out with a spade if extra firm, and the plants inserted with a strong dibber or a crowbar, and well watered in. At the present date (June 12) we still have some heads of Broccoli usable, while the autumn-sown quarter of Erfurt Cauliflowers is also furnishing beautiful white heads, and have been ready several days. H.

SOCIETIES.

ROYAL HORTICULTURAL.

JUNE 15.—A meeting of the committees was held in the Drill Hall, James Street, Westminster, on Tuesday last, being the first ordinary meeting after the Temple Show. An extensive exhibition could hardly have been expected therefore, but the hall nevertheless was well filled, and exhibits of one sort or another were numerous, and some of them good. The two weakest features were Orchids and fruit; there were few exhibits of the former, and of the latter there is expected to be no unusual request next week in connection with the Queen's Commemoration, that it was not surprising was not present in large quantity. Fronics, Fuchsia, Irises, and other summer flowers from out-of-doors accounted for the greater part of the space, and the rest was of the usual miscellaneous character.

Floral Committee.

FAYERS, W. Marshall, Esq., in the Chair; and Messrs. Jno. Fraser, E. Hunt, J. H. Hobbs, G. Nicholson, G. Gordon, John Jennings, C. J. SALTER, C. Jeffries, J. D. Parke, Chas. F. Pearson, Chas. E. Shea, H. J. Jones, J. W. Walker, Ed. Beckett, H. J. Orbach, Chas. Black, H. Turner, Geo. Paul, R. M. Hugg, and Ed. Mawley.

Mr. THOS. S. WALKER, Hale Farm Nurseries, Tottenham, showed a collection of hardy flowers, conspicuous amongst which were many fine Irises. An Award of Merit was recommended to a variety of *I. germanica* named *in xima*, a handsome, large flower. Several sprays of the purple-flowering *Arum*, *Dracunculids* were noticed. The remainder of the flowers represented a variety of species of useful hardy flowering plants (Silver Banksian Medal).

A group of Carnations in flower from Messrs. J. PECK & SONS, Rouppell Park Nurseries, London, S.E., contained several good perpetual-flowering varieties. Mr. H. H. MESSURES, Cole's Improved Perpetual Cherry, and Miss MESSURES, all scarlet-crimson siles of some merit. A few pink-coloured *Souvenir de la Malmaison* were included also (Silver Flora Medal).

MESSRS. W. PAUL & SONS, Waltham Cross Nurseries, Herts, showed a group of plants in flower of their new creamy-white-flowering Tea Rose, *Enchantress*.

A group of Cannas from Messrs. H. CANNELL & SONS, Swanley, Kent, made a gorgeous display, the colours being exceedingly bright and rich. It was one of the best exhibits of Cannas we have seen, and the group included a great number of the best new kinds, including *Italia* and *Austria* (Silver Flora Medal).

MESSRS. FRANK COYNE & CO., Braidswick Nursery, Colchester, made a lovely display of garden Roses, shown in good sized bunches. The variety of flower and foliage was considerable, some with flowers from 4 to 5 inches across, others as small as a sixpence. A few of the more prominent were Paul's Carmine Pillar, Brenda, Austrian Copper, and Austrian Yellow. Grandiflora, and a few of the fine hybrid Sweet Briars (Silver Banksian Medal).

MESSRS. KEENEY & SONS, Longport, Somerset, made a very gay exhibit of Peony flowers in great variety, and some of their excellent Delphiniums, two of which were recommended an Award of Merit. The variety *Sir John Forrest*, a dark purple-blue flower, with creamy-white centre, and *Clara Stubbs*, decidedly blue, Rocket's blue shoot, with a white centre; the flowers in each case were large and good (Silver Flora Medal).

MESSRS. R. WALLACE & CO., Colchester, had a beautiful and extensive exhibit of Lilies, Irises, and Calceolaries. An Award of Merit was recommended to *Calochortus oregonensis*, a moderately large, rather spreading flower, of white or cream colour, the yellow stamens being produced from a green ground. Varieties of *C. venustus* and other species were very fine. *Lilium Alpinum* was represented by a large

number of varieties of many shades of colour, and exceedingly pretty. *Lilium Flammarum* s, and *L. umbellatum* were each displayed in some variety. The collection of *Brodiaea* included fine umbels of the blue-flowered *B. laxa*, also *B. congesta*, and the singular-looking *B. coccinea* (Silver Flora Medal).

MESSRS. DUNN & CO., Bishops, N.B., and Orpington, Kent, had a large exhibit of flowers of decorative varieties of *Polygonatum*, double-flowered *Dabbias*, and their single-flowered *Cactus* varieties; but their best display was one of *Pyranthem roseum* flowers in sprays. These were very fine, and included flowers of many shades, from Gloire d'Italie, deep rose-red, to *Aphrodite*, white light (Silver Banksian Medal).

MESSRS. G. COULSON & SONS, Bath, exhibited flowers of garden roses in the well-known style and arrangement, among them we noticed sprays of Couling's single *Crimson Bolder*. It has large single flowers of effective colour, and is apparently unusually free. The Sweet Briars and Austrian Briars were well represented, and a few blooms were shown of a white-flowering hybrid Tea Rose named *Purity* (Silver Banksian Medal).

MESSRS. C. PAUL & SONS, Chesham, made a good display of garden Roses, and also of Peony flowers and alpine plants. An Award of Merit was recommended to *Rose macrophylla*, a pretty single rose-coloured flower, with smooth deep green leaves. A very fine variety of Peony named *Whitney*, also from Messrs. PAUL & SONS, was recommended an Award of Merit.

From H. J. EYLES, Esq., Colchester Park, Andoversford, came a large flower of a species of *Arum*, probably a variety *A. Dracunculoides*.

Mr. F. W. MOORE, of the Glasnevin Botanic Gardens, sent several interesting flowers, including *Abutilon vitifolium* album, a variety with white, flat flowers, something like a *Queen Anemone*, double-flowering *Anemone* King of the Scarlet, *Hemerocallis Catherine*, and a spray of the yellow-flowered *Fremontia californica*.

MESSRS. JAS. VEITCH & SONS, Royal Exotic Nursery, Chelsea, showed a group of plants which included *Olearia striata* and *V. crumena*, a plant with slender growing dwarf plant with pale red flowers; also *Raphanoides japonica*, several Oaks, including *Quercus eufertii* and the golden-leaved *Q. pedunculata* *Concordia*, *Coprosma macrocarpa* *lutea* (a very ornamental variety), *Hydrangea quercifolia*, *Vernonia prostrata*, *Ternstroemia* *Africana*, and *Viburnum Mariani* and *V. molle*. There were also some other specimens of several varieties of *Nymphopeltis* *N. Lyallii*, and *N. odorata*.

MESSRS. VEITCH & SONS also made a grand display with Peony blooms in variety, and their excellent strain of *Apollonia* was shown (Silver Flora Medal).

They were awarded a Certificate for a fine golden-coloured *Colinus atlantica*, *C. a. aurea*. They also showed a few fine *Fragles*, representing their spotted varieties of *Digitalis purpurea*, and a hybrid strain obtained from crossing *D. ambigua* with *D. purpurea*. The flowers are light rose-coloured, spotted inside, and the leaves are considerably those of *D. purpurea*.

An Award of Merit was recommended to a very pretty Fern, *Pteris (Dryopteris) nobilis*, about 5 inches high, of deep olive green; and a First class Certificate to *Columia Munro*, which grows from 1 to 2 feet high, produces a fairly large single flower, with white ray florets and yellow centre. *Phlox* *longicaulis* was shown to be a hybrid from *P. macrantha* and *E. Philippina*. The foliage and flowers are considerably smaller than those of *E. macrantha*, and the blooms are pale rose in colour (Award of Merit), all of which came from the Veitchian establishment.

Some splendid flowers of *Iris*, *Cattleya* were sent by C. G. VAN TUBBERGEN, Haarlem, Holland. As mentioned in these pages last week, this *Iris* (figured in the *Gardener's Chronicle*, vol. viii, p. 17), is an exceptionally desirable variety.

An Award of Merit was recommended to a pure white-flowering Pink named *Albino*, shown by Mr. T. GIFFORD, Tottenham, and by Mr. LAWSON & CO. The terminal flower of the first-named exhibitor were very much the better. It is a fragrant variety, very pure, and the petals smooth—altogether, a variety of some merit. Mr. Gifford also exhibited *Delphinium* and *Potamocharis*.

From the Gardens of the Society at Chiswick were exhibited some *Fuchsia* grown there from seed sown by Messrs. LAWSON, Andrews & Co. The terminal flower in each case was empanulate; and it appears that this malformation, that we have noticed again and again, has become so fixed that it comes true from seeds.

Mr. C. DUMMETT, 8 Ashmole-st., exhibited a group of plants of a decorative variety of *Polygonatum*, named Harry Dymott. It appeared to be of free-flowering habit and average merit. Mrs. A. W. YOUNG & CO., Stevenage, Herts, were awarded a Bronze Banksian Medal for a group of hardy flowers. A Silver Banksian Medal was awarded to Messrs. J. CHEAL & SONS, Lowfield Nurseries, near Crawley, for an exhibit including a good display of hardy flowers, such as Irises, *Fuchsia*, and *Viola*, and a few sprays of flowering and ornamental varieties of trees and shrubs.

Mr. B. LADMAN, Shirley Nurseries, near Southampton, was awarded a Silver Banksian Medal for a fine exhibit of Pinks, including several new varieties, and a few sprays of varieties of *Campanula persicifolia*.

The exhibit from Messrs. BULL & SONS, King Street, Covent Garden, included as usual a representation of most of the hardy bulbous plants now in flower. Irises particularly were very fine. *I. variegata* in the varieties *auri*, *Maori*, *alba*, and others. *I. pallida* var. *Albert Victor*, Spanish *Iris* *Thunderbolt* and *Princess Ida*, very pretty yellow,

Peonies and other flowers were well shown (Silver Flora Medal).

Mr. CHAS. TURNER, Royal Nurseries, Slough, exhibited a group of Carnations composed of most successfully-grown plants, and representing such choice varieties that Awards of Merit were recommended to the four following:—*Water-witch*, white or palest flesh, very fine; *Helmstam*, also white, but not so pure, and of exquisite form; *Barres*, deep rose red, very large; and excellent in form; and *Cecilia*, yellow self, nearly 5 inches across, and of shapely form.

A varied and pretty group of hardy herbaceous plants and flowers from Mr. M. PATTENBERG, Christchurch, was awarded a Silver Flora Medal.

Orchid Committee.

Present: H. J. VEITCH, Esq., in the chair; and Messrs. J. O'BRIEN (Hon. Sec.), De B. CRAWSHAY, H. BULLMAN, F. SANDER, H. WILLIAMS, W. H. WHITE, E. HILL, J. GORDON, A. H. SNEE, W. H. YOUNG, H. J. CHAPMAN, C. COURTAIN, J. DUNGLAS, and T. B. HAGROD.

Sir T. LAWRENCE, Bart., Barford, Dorset (gr. Mr. W. H. White), staged a small group of specially interesting Orchids, among the most remarkable was the long-looked-for hybrid *Vanda* × *Miss Joaquim*, now flowering for the first time in Europe. The plant was obtained from a cross between *V. teres* and *V. hookeriana* some years ago by Miss botham of Singapore. The specimen shown had attained the height of between 7 and 8 feet, and produced an inflorescence with three fully-expanded flowers and nine buds. In size and in the form of the sepals and petals, and also in its rose-colouring, with orange disc to the lip, the flowers partook much of *V. teres*, but *V. hookeriana* was well shown in the openly displayed side lobes and broad front-lobe of the lip (First-class Certificate).

Sir T. LAWRENCE also showed the white-flowered *Geodorum Augusti* (Botanical Certificate); a charming plant of the cream-white *Chloropetalum nutans* with many spikes (Cultural Commendation); *Aeranthus caperophorum* of the botanical Society; *Chloropetalum nutans* (Cultural Certificate); *Laelio-Cattleya* × *Entropie*, *Dendrobium crystallinum*, and a grand inflorescence of *Phallopis amabilis* (grandiflorus).

MESSRS. JAS. VEITCH & SONS, Royal Exotic Nursery, King's Road, Chelsea, had a very fine group, which secured a Silver Flora Medal. In it were *Cypripedium* × *Messures*, *Veitch's* var. *superbissimum*, *Chloropetalum nutans*, a very fine variety, the reverse cross of the original *C. X Messures*; two pretty and distinct forms of *Laelio-Cattleya* × *Canhamiana*, that named *Langleyensis* being a very fine light variety; the handsome *Epiphrasinus* × *Veitchii*, *Zygocloax* × *Veitchii*, *Laelio-Cattleya* × *eximia*, *L. C. X Hippolyta*, *Lilia* *Novella*, varieties of *L. purpurata*, and *L. tessellata*; *Cymbidium* *chamisso-Lovi*, *Cattleya* × *calumbata*, *C. Walkeriana*, fine varieties of *C. Mossie*, *Dei Brouha* *Phallopis*, *D. Bensonii*, *Dixax* *Veitchii*, fine forms of *Cattleya Mendellii*, *Cypripedium grande*, *C. superbissimum*, *Bletia venusta*, &c.

MESSRS. BROWN LOW & CO., Cheltenham, showed *Cattleya Mossie* ("In Memoriam Richard Coward"), a magnificent flower of great size and rich and bright colour (Award of Merit); the white *C. Mossie* *Wagneri*, *C. M. Aruoliiana*, and *C. M. Reinckiana*; *C. M. M. R. Ashworth*, a light form, with slate-coloured markings on the lip; *Laelio-Cattleya* × *Aphrodite*, *Luliv tenobrosa*, *Bulbophyllum chaptaliaense*, &c.

MESSRS. F. SANDER & CO. exhibited three fine novelties, each of which secured an Award of Merit, viz., *Laelio-Cattleya* × *Empress of India* (*L. purpurata* *Bryskia* × *C. Dowiana*). The sepals and petals were lilac-rose; lip crimped at the margin, dark purple-brown with yellow centre; *Cattleya Mossie* "Empress of India," a grand flower, much resembling that shown by Messrs. Low; and *Laelio-Cattleya* × *Our Queen*, of unrecorded parentage. The plant bore very pretty and finely-formed white flowers, with purple front-lobe, the lip which had an orange throat and broad white margin.

Sir F. WIGAN, Clare Lawn, East Sheen (gr. Mr. W. H. Young), showed *Laelio-Cattleya* × *Orphanum*, a grand flower of the *L. C.* × *eximia* class, but with large maroon crimson lip, with orange disc; *L. C.* × *Canhamiana* *lolanthe*, very finely flowered; the distinct *Cattleya Mossie* *Mrs. Egerton Grey*; a fine rose coloured form of *Miliona*, s. *tabula*, with darker purplish markings on the lip; *Epidendrum Melius*, with eight flowers; *Cymbidium tigrinum*, *Miliona vexillaria*, *eximia*, varieties of *Cattleya Mendellii*, &c.

De B. CRAWSHAY, Esq., Rosfield, Sevenoaks (gr. Mr. S. Cooke), showed *Odonoglossum crispum* *Crawsayana*, *Thelysion*, *Chloropetalum nutans*, which were well shown, but not so good, and when mature will be a superb form (Award of Merit).

R. L. MESSURES, Esq., Cambridge Lodge, Camberwell (gr. Mr. H. J. Chapman), showed *Lelia purpurata* *Ernesti*, a very pretty variety of the *L. P.* *Schroderiana* class, with white flowers, slightly tinted with sulphur yellow, the disc of the lip being soft, light rose; the base yellow, with narrow purple lines. Mr. Messures also showed *Lilia tenobrosa* *superba*, a dark variety, in which the reddish maroon markings in the centre of the lip contrasted with its light blue-rose front; and the singular *Miliona vexillaria*, Cambridge Lodge variety, in which the petals are unusually broad, and each segment bears red lines like those on the lip.

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr. Mr. Adams), showed two flowers of *Angulo* *Titiana*, with bluish-white flowers. The column and lip appeared distinct from those

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending June 12, is furnished from the Meteorological Office:—

The weather during this period varied greatly, but became fine and bright generally towards the end of the week. Rain was of frequent occurrence over England and Ireland during the earlier half of the week, and over Scotland during the latter. Thunderstorms occurred from time to time in different parts of the kingdom, that experienced in London on Sunday being accompanied by extremely heavy rain in some of the southern and south-eastern suburbs.

The temperature varied greatly, but was, on the whole, above the mean, although it showed a deficit over Scotland, and just equalled the normal in England, N.W., England, N.E., and England, E. The highest of the maxima were registered on the 14th, which ranged from 85° in the Midland Counties, and from between 80° and 82° in the other English districts, to 75° in Ireland, S., and 72° in Scotland, W. On the 5th and 9th, the maxima had been very low, being less than 50° at some stations, and below 50° in most parts of Great Britain. The lowest of the minima, which were recorded, as a rule, during the middle of the week, ranged from 31° in Scotland, E. (at Nairn), and 35° in Scotland, N., to 45° in Ireland, N., and 49° in Ireland, S., and the Channel Islands.

The rainfall was considerably more than the mean in most districts, but was less than the normal in Scotland, N. and W., England, N.E., and the Channel Islands. The falls recorded over the southern parts of England in the 8th ranged between 60 inch and 110 inches.

The bright sunshine exceeded the mean in the Channel Islands, but was deficient elsewhere—especially over Ireland and Scotland, W. The percentage of the possible duration ranged from 50 in the Channel Islands, and from 42 in England, S.W., to 19 in Scotland, W., 11 in Ireland, S., and only 7 in Ireland, N.

IMPROVEMENTS ON THE ISLAND OF SCALPAY.

Sir DONALD CURRIE, ever since he became proprietor of this beautiful island, has been laying out very large sums of money in making it a comfortable residential Highland resort. On the north, south, and west shores of the island, Sir DONALD has laid out several plantations, which will ultimately add much to the beauty and shelter of its lovely shores. These plantations have just been completed. Nearly 1,500,000 trees have been planted in them, chiefly Scotch Fir, Larch, Spruce, and Birch, with a considerable variety of finer kinds. The whole work has been successfully carried out by Messrs. HOWDEN & Co., nurserymen, of Inverness, although under circumstances which were often very adverse, owing to stormy weather and the scarcity of labour. With characteristic energy, Sir DONALD has pushed on work of all sorts, and even now Scalpay is one of the most complete establishments in the Highlands of Scotland. Old Scalpay House is entirely obliterated, and a new mansion has taken its place; new gardens have been added; new roads have been made, and others are in progress; and new farm offices are completed. A pier has been planned, and extensive water arrangements have also been carried out.

CARNATIONS: *G. D.* Your plants are afflicted with eel-worms in the leaves, often figured and described in these columns. Burn your plants, turn out the old soil, and get fresh.

CRICKETS IN CUCUMBER-PITS: *E. J. Seymour & Co.* We take these means of destroying crickets from a book of garden recipes. "Mix roasted Apple with a little white arsenic powdered; divide the Apple so prepared into small pieces, and place it in saucers in the pits at night. Take one pint of oatmeal and two ounces of arsenic, together with a little ground aniseed and caraway-seed. This should be laid on pieces of paper in convenient places. Arsenic and honey may be mixed together and laid about for them. Lay it in bits on pieces of glass on the inside of syster-shells; it is necessary to use something that has a hard surface that will not absorb moisture from it, or it will be so dry after the first night as to render it useless. Rhubarb leaves are said to be a cure for crickets." Perhaps the cure for ants which we advised you

try may be effective against crickets. Do not forget that arsenic is a most powerful poison. Use it with every possible precaution.

BURHARS: *M. B.* Your bulbs are attacked by the bulb-mites. As the creatures are inside the scales, no application is likely to be of much use. Grow them on as well as you can, in the hope that by increased strength the plants may resist the attack—or better, burn them.

GLOXINIAS: *G. H. H.* These hose in hose flowers, the result of a too nourishing diet, are not uncommon, but they are rarely inherited by the plants raised from them by seeds or leaf cuttings. We, however, see the abnormality perpetuated with fair constancy in the double varieties of Canterbury Bells.

MILDEW ON ROSES: *J. O. R.* Some good cultivators prefer to rely upon soft-soap dissolved in cold water alone; Mr. Maycock being one who does so. Others like to employ flowers-of-sulphur as well. The following is a good recipe:—Soft-soap, 1 lb., boiled in 4 quarts of rain-water for ten minutes; then add 1 wineglassful of petroleum, and 2 of sulphur on removing the saucenpan from the fire. Decant into a stone jar, and cork tightly. It will make from 18 to 20 gallons when diluted fit for use.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*A. J. Cork.* 1, *Heuchera sanguinea*; 2, *Cercis siliquastrum*, Judas-tree; 3, *Conoclinium lanthimum*.—*W. T. Carex paludosa*.—*C. L. W.* 1, *Euphorbia Lathyris* (Caper Spurge); 2, *Ajuga reptans* (Bugle).—*J. E.* *Physalis peruviana* (the Cape Gooseberry).—*A. G. W.* *Orthogalum nutans*, or *O. pyrenaicum*; we cannot tell which from the specimen sent.—*L. C. T. H.* The one with the purple lip and light-yellow spots on each side is *Cattleya Warscewiczii*, commonly known in gardens as *C. gigas*. The other is *Cattleya lobiata* Gaskellians.—*M. C.* *Rothsay*. 1, *Livendula dentata*; 2, *Libonia floribunda*. The others are *Selaginella Wildenovi* of gardens, and *Cestrum fasciculatum* (*Habrothamnus fasciculatus*, *Bot. Mag.*, 4189).—*G. E.* *Silviculture*. The flower is not that of *Dendrobium fimbriatum oclatum*, but of *D. moschatum*.—*J. C.* *Fifeshire*. 1, specimen insufficient; 2, *Tecoma australis*; 3, *Oxalis Martiana*; 4, *Acor polyrrhizum*; 5, *Pellonia Daveana*; 6, *Pellonia pulchra*.—*P.* *Clematis Lady Bovill*. If the climbers are drawn back from the walls and fastened to stakes, and as many of the stems as possible preserved, they could be fastened in their places again after the painting was done, and they would probably not feel the change much.—*G. Francis.* *Dendrobium moschatum cupreum* (*Orchid Album*, plate 165).—*E. M.* Seed some blooms to a Rose nurseryman; we cannot name them with certainty.

NECTARINES: *H. H.* The trees from which the leaves sent were taken are evidently suffering from bad management. We would advise that the trees be lifted in the early autumn, getting out the whole of the roots with as little injury to them as is possible, wrapping them in wet litter until new stations can be prepared. With the idea of getting them into a fruitful condition the branches have been very severely pruned, a mistaken practice once commonly followed. Doubtless the gumming will cease in the course of the next growing season. The border consisting of very stiff soil, it may be advisable in making the border anew to wheel out most of it, replacing it with fresh turfy loam, liue-rubbish, and charred garden-refuse, putting these materials together in a compact manner after mixing them, and making the border 6 inches higher than before to allow for sinking. The trees may then be planted with their roots from 6 inches to 4 inches from the surface, covering these with loam which has been stacked for one year, sifted potting-bench-refuse, and a small quantity of spent hot-bed manure or leaf-mould, into which they will soon push. Whilst filling in this mixture about the root, copious waterings with a large rose can may be afforded, which will compact it about the roots better than can be done in any other manner. Afford the entire border a thorough watering, and supply a slight mulch of litter. If the lifting be done with the leaves remain on the trees, it will be advisable to retain them in a fresh condition for a month or longer by ventilating the house moderately, and syringing the trees late in the afternoon, not however closing the house at night. When the leaves assume the tints of decay, give

ample ventilation, and keep the trees cool at top but not dry at the root. During the present summer lay in only such young wood as is likely to be fruitful, and as much of it as may be required to furnish a crop of fruit and no more. This wood, if it be laid-in at 8 to 12 inches apart, should get perfectly ripened.

ORCHIDS: *J. R.* The *Cattleya Mossiae* is not more than a good average variety. The *Lelia tenebrosa* is above the average in size, and the blotch of purple on the base of the lip not more than ordinarily dark, and rich in colour.

PELAGONISUS: *J. S.* There was no trace of fungous disease, neither has any appeared since, in a plant grown on for experiment. *G. M.*

RHODODENDRON GRAFTING: *W. C. F.* As the nearly-ripened shoots are the best for grafts, and these are not obtainable before July, the grafting of the plants has to be done at a time of heat and drought, and the operation is not very successful when done out-of-doors. Besides, headed down old plants of *R. ponticum* scarcely offer the best stocks for grafting purposes. When a *Rhododendron* is grafted, the shoots or stem operated upon should be furnished with, at the least, one pair of healthy leaves just above the point at which it is headed-back, whether left, tongue, or whip grafted by the methods employed. And the grafted plants are usually kept in a close box or case within a greenhouse—or better, on a little warmer. In the case of the old stools that you wish to graft, if you could cover them with a frame or hand-light that is practically air-tight, success would attend the operation if you grafted by the approach or inching, i.e., by sinking pots of the ennobled varieties you wish to place on the stools round about them. Good strong pieces can in this method be affixed to the stocks, which soon make a good crown or bush. The part below the point of union is cut off close to the letter when it is seen that it is no longer required for the support of the graft. Inarching young stocks grown one year in pots is a method commonly adopted by nurserymen. All that has to be done is to sink as many of these round the mother-plant as there are shoots to be inarched. This is done in late summer, and the point of union is clayed or waxed, and mossed over in the usual manner, the plants being sprinkled with water morning and evening, and the old plants not allowed to get stocked in growth for lack of moisture in the soil.

STRAWBERRIES: *J. J. R.* The fruits are well-developed, and have suffered considerably from the ravages of slugs, and from blows caused by hail. There was no appearance of any mildew or other fungus.

TOMATOES: *A. McDonald.* The flowers are imperfectly or not at all fertilised. This may be a constitutional defect of the variety, or brought about by excess of humidity in the air and lack of ventilation.

TOMATOES: *Wm. Lenington.* Try the effect of the Bordeaux Mixture on the plants. It may be employed once in three weeks as a preventative of fungus attacks, and to kill the fungus if it should obtain a footing on them. Before using it over all of the plants in a house, first ascertain in what state of dilution it is safe to use it on the plants. Directions for making the mixture have frequently been given in these pages.

WOODLICE IN THE MUSHROOM-HOUSE: *J. J. Char* out mouldy hay and anything that affords a harbour for them, and then pour boiling water between the Mushroom-beds and the walls and partitions, and dash it beneath the hot-water pipes, and into all likely hiding-places. Carbolic acid or borax strewn about may render the place untenable for the insect. The water cure must be followed up for a fortnight or longer. Roofing-slates laid on the floor about a quarter of an inch above it make capital traps for woodlice.

THE

Gardeners' Chronicle.

SATURDAY, JUNE 26, 1897.

CLAREMONT.

TO alight at a station bearing the name of Claygate, to tramp along a mile or so of dusty road, passing through a scattered hamlet, scarcely seeing a fellow-traveller on the way, unless it be the ubiquitous cyclist, makes one feel that one really is in the country. Nevertheless, it is but a matter of a dozen miles from the centre of London, and between it and that centre there are such places as Wimbledon and Surbiton, suburbs with the population of good-sized provincial towns.

The transition between London and its suburbs is mostly gradual, from one form of unloveliness to another; but here, after passing Surbiton, we swerve suddenly on our course, and looking down upon Messrs. Barr's mosaic nursery as we pass, find ourselves almost immediately in the country. In places, masses of glowing Broom and Gorse tell us we are on light soil, a sandy loam used for brick-making, and thrown up into low undulations and tree-topped hills. It is the middle of May, the trees are bedecked with new leafage, but there are traces of the recent occurrence of sharp frost. Eleven degrees, we were told, had been recorded a night or two before our visit (on May 14); at any rate, here and there young Ash-shoots were reduced to friable tinder, Lime-shoots were browned, and Beech twigs hung limp, as if parboiled, their nascent energy thus quickly brought to a standstill. In the gardens, the presumably delicate exotics had suffered less than the natives, partly, no doubt from the greater amount of protection to be had. But we are anticipating. We have not reached the garden yet. Passing through the entrance-hedge, we walk knee-deep in Buttercups and rich grass, noting farm-buildings and an obelisk on the left, and seeing before us a low hill crowned with a fine group of Scotch Pines, with little or no trace of gardens, pleasure-grounds, or mansion. A quaint brick-gateway in an old wall at length reveals itself. We lift the latch, and are at once in an old-world garden, encased by high brick walls, perforated by innumerable nail-holes, wherein generations of gardeners have affixed the shoots of Pears and Plums, and which remain as monuments of past labour, even as wires and cordons now attest the work and skill of the present. In passing, Mr. Burrell tells us that in some cases the Pears are better on the Pear-stock than on the Quince, which exerts too restrictive an influence, so that the growth is stunted. Probably this applies to certain varieties only. At the base of some

of the walls are herbaceous borders, and a long row of *Polyanthus* and *Primroses* of good strains.

The walls, erected by Sir John Vanbrugh, date from 1704, the year that Gibraltar was captured. They serve to portion off three or four separate enclosures, some are clothed with fruit-trees, others are draped with the festoons of the *Wistaria*, or radiant with the pink flowers of the *Judas tree*. *Spirea prunifolia*, the double form, swaths a pilaster with a sheet of white blossom. The white variety of *Pyrus japonica* covers another stretch of wall with its porcelain-white flowers. *Gloire de Dijon* Roses are blooming freely, and clusters of the yellow *Banksian* Roses form a marked contrast to what we had seen not half an hour since, when we were gathering dead leaves of Ash, Lime, and Beech. Potato-tops inside the walls were nevertheless blackened, but Peas seemed uninjured. Raspberries and Gooseberries are grown on trellises, Mr. Burrell getting a profusion of excellent fruit from his Gooseberry-trellises. Hereabouts is an old high-roofed half-span greenhouse, in two compartments, tenanted with *Azaleas*, *Calceolarias*, white *Arums*, and miscellaneous plants of that character. Some gardeners would complain that the plants must be too far from the glass. They do not appear to suffer in any way here—indeed, it is rare to see plants so clean and healthy in old structures like these.

The frame-ground contains the usual houses and pits for the supply of a large establishment, but it was the trees that formed the special object of our visit, and there are, indeed, some not-worthily ones. The king of them is one that stands near the gardener's house, *Pterocarya caucasia*, a near ally of the Walnut, with long pendulous racemes of three-winged nuts (see fig. 47, in *Gardeners' Chronicle*, Sept. 29, 1894).

The young leaves had suffered from the recent frost just as Walnut-trees are apt to do, but the injury will soon be repaired. This tree has a short bole, with a girth of some 13 feet at 3 feet from the ground, whilst the circuit of the branches is about 100 yards. The leaves were only partially expanded, so that we did not see the tree to perfection. Near his majesty, as we may call him, is a good specimen of *Laurus Sassafras*, that one does not often see, a symmetrical *Wellingtonia* of good size, and a *Maidenhair-tree* (*Ginkgo biloba*) with a flush of yellowish-green, always interesting, but now more than ever so since the recent discovery by some Japanese botanists of peculiarities which link it on really, and not merely apparently, to Ferns and Cycads. Not far off is a good specimen of *Taxodium distichum*, not so fine as at Sion, but still remarkable for growing so freely on a dry soil. It has not as yet thrown up any of the peculiar knobs from the root which characterise the growth of this tree. The head is constituted of nearly horizontally-spreading branches breaking up into a spray of fine ascending branchlets, forming a marked contrast to the scanty, loosely-dispersed, fat, beaded branches of its neighbour, *Gymnocladus canadensis*, one of the latest of trees to expand its foliage, and with its buds still closed on this May 14.

Another "hole in the wall" gives access to a paddock, traversing which the mansion is soon reached. It is a decidedly imposing square building, of classic architecture, erected by Brown for Lord Clive, placed on rising ground, and looking over hill and dale.

And here we may pause for a moment to recall the tenants this house has had, including the Earl of Clare, from whom the place derives its

name; the Duke of Newcastle, in whose times the grounds were improved by Kent; Sir John Vanbrugh; Clive, one of the founders of India; the Princess Charlotte, daughter of George IV., who occupied so large a share in the affections of the people; and her husband, King Leopold of Belgium, who offered it as a refuge in 1848 to King Louis Philippe in his exile. Ultimately it became, and still remains, the property of Her Majesty, who has assigned it for the present use of H.R.H. the Duchess of Albany, the widow of the clerical Prince Leopold.

The Duke and Duchess of Kent, after their marriage at Kew Palace, on July 11, 1818, went, we are told, to Claremont; and the Queen herself shortly after her marriage, retired to Claremont to escape London. The happiest days of the Queen's childhood, indeed, she tells us herself, were spent at Claremont. "The time spent there," she adds, "was always a very happy one, the Queen and the Prince being able to take charming walks in the pretty grounds and neighbourhood." From 1840 to 1848, with the exception of 1840, it was the practice of the Queen to pass her birthday, May 24, in quiet retirement; and no wonder, for the charm, variety, and reposeful beauty of the pleasure-grounds are seductive to no small extent.

It is impossible to convey more than a general impression of woods and glades, dells and swelling undulations, and clear, glassy pools—a good specimen of English park scenery, in fact. Unfortunately, the rabbits have rather more than their share of the amenities, as they are shocking landscape-gardeners, and voracious destroyers of what a plant-lover holds in estimation. Beech is the prevailing timber, and there are some noble specimens, with a few Scotch and Silver Firs intermixed. *Abies cephalonica* and *A. brachyphylla* are doing well, but *Cunninghamia lanceolata* looks, as it does everywhere else, rather miserable—an exile, who cannot adapt itself to its new conditions. *Magnolia macrophylla*, fine old Cork-trees, a particularly elegant form of *Cedrus atlantica glauca*, fine Cedars of varied habit—one with a straight unbranched bole of considerable dimensions, and quite different in habit from Cedars generally. That reminds us that in the garden proper near the *Gymnocladus* is a fine *Deodar*, one of the finest we know, but which we took at first sight to be a *Cedar of Lebanon*; till more careful scrutiny revealed the fact that it was a *Deodar*, and afforded another illustration of Sir Joseph Hooker's dictum, that "habit" alone is a most treacherous guide in discriminating species of Conifers.

Reverting to the pleasure-grounds, we come to an observatory perched upon a hillock, and now used as a gymnasium; and a little further on we come unexpectedly on a stone conservatory placed on a terrace overlooking a slope and the opposite woods. This conservatory is full of *Camellias* planted out, and in excellent health; among them is one named *conspicua*, brought from Napoleon's residence in Corsica by H.R.H. the Duke of Albany. The undergrowth in the pleasure-grounds is almost entirely common Laurel, kept cut down. It is very suitable, but a little more variety and admixture of *Mahonia*, *Rhododendrons*, common *Bracken*, or anything else that Master Rabbit might allow to remain, would add variety to the whole. In the midst of the woods we find a memorial structure, in the Gothic style of the period, containing a bust of the Princess Charlotte, and which impresses the spectator with the feeling

that it must have been a good likeness. The view from the terrace in front, looking over the little lake, is very lovely. Hereabouts are the "children's gardens," kept neat and tidy, and overlooking glowing masses of Rhododendron and Azaleas; and so we wander mid the trees, till at length we find ourselves once more within the circuit of the much-benailed walls.

These serve to remind us that Claremont has had some distinguished gardeners in its time. John Greening, gardener to the Duke of Newcastle, raised the Claremont *Nectarine* from the Elbruge so long ago as 1750. Many years later, when Orchid culture was little practiced and less understood, it is recorded that Fairbairn succeeded in inducing *Aerides odoratum* to produce flowers by placing it in a basket of spent tan and moss hung in the Pine-stove and dipped in a bucket of water half a dozen times a day (H. J. Veitch, *Journal of Royal Horticultural Society*, xi., p. 115). In later years McIntosh, the author of the book *The Garden* had sway here. Subsequently he went to Dalkeith, where the Queen mentions in *Leaves from the Journal of our Life in the Highlands*, having seen "McIntosh, who was formerly gardener at Claremont," and who was then engaged in the construction of the new garden (1812).

But we have come to the end of our walk, and thanking Mr. Burrell for his courtesy, we betake ourselves once more to the dusty high road and the quiet station, whose size, together with rising houses and plotted areas near it, give indications that the rural character of the place will speedily be very much a thing of the past. Happily, Claremont will still remain Claremont.

PLANTS OF THE VICTORIAN ERA. ORCHIDS.

THE introduction of Orchids into British gardens commenced more than 150 years ago, and these now favourite plants then considered curiosities, were subjected to very remarkable treatment, well calculated to suppress their beauties. Their numbers, however, steadily increased, until, in 1818, the typical *Cattleya labiata* presented one of the first of the more ornate section of Orchids, but the interest it excited was not followed up, and Orchids still remained rare and curious as they had always been until almost contemporaneously with the Accession to the Throne of Queen Victoria. Then a new era soon began, and Orchids were taken in hand with enthusiasm, both as to their introduction and culture, one of the pioneers being the veteran, James Bateman. A very remarkable event at once presents itself in considering the showy section of *Cattleya*, and that is, that the fine *Cattleya Mossie*, which created such a sensation about the first year of Her Majesty's reign, should, throughout the intervening sixty years, remain a favourite plant, and that a variety of it should be illustrated in the issue of the *Gardeners' Chronicle* for June 12 as *Cattleya Mossie* "Queen-Empress."

Practically all the more showy Orchids in gardens have been introduced during the Victorian Era, a great many of them, such as the Mexican *Ladlas*, *Cattleya Skinneri*, and many others, having either been discovered or first flowered in 1837. Soon after came the discovery by Hartweg of the now-famous *Odontoglossum crispum*, which on its introduction was named in honour of Her Royal Highness, Alexandra, Princess of Wales. Still nearer our day, the showy *Miltonias* and *Dendrobium Phalaenopsis*

were brought out, and one of the most important events in Orchid history occurred, viz., the re-introduction of the typical *Cattleya labiata*, so frequently sought for since its introduction in 1818, and with it the beautiful natural hybrid, *Lælio-Cattleya Victoria Regina*, illustrated in our issue for June 25, 1892.

Primarily, the successful culture of Orchids in the present day is due to the careful observation of their habits and requirements made during the past sixty years, and the consequent improvements in the structures in which they are grown, and especially in the matter of heating and ventilation. When the culture of these plants came to be better understood, and their real beauties revealed, extensive collections were formed. But in the olden time the collectors were satisfied with one or two specimens of a kind. Later, when the beauty and usefulness of their flowers for decorative purposes came to be known, some growers

which, when turned out of the pot, would weigh but two or three ounces.

The commercial interest in Orchids is, and always has been, strong; and as soon as large quantities of showy kinds were acquired cheaply, the market-grower and florist for cut flowers came to the front; and now there are many establishments, both nurserymen's and amateurs', who derive large sums of money from cut-blooms of Orchids. Sometimes they are dear, sometimes cheap, and the variation in price only tends to popularise them, for they are to be seen at State functions, and also, when the market is easy, in the baskets of the street-seller of button-hole flowers.

But the greatest departure in the reign of Victoria has been the raising of hybrid Orchids in gardens at home—an industry which runs introduction by importation very close, and which should commend itself to all, as the benefits arising from the home-made article are evident.

And what does this hasty review disclose? The careful and successful pursuit of beautiful and interesting subjects made easy as one consequence of a long reign of peace and progress.

VEGETABLES, 1837—1897.

In reviewing the relative conditions of vegetable culture, now and sixty years since, it will not do to leap to the conclusion that there has been so marked a development as has characterised fruit culture. We grow the bulk of our vegetables in the open air now, as our fathers did early in the century, and those who have read the cultural details given in the "thirties," with respect to all kinds of vegetables, have to admit that these details apply with similar force to the present time. In the case of a few subjects, notably Tomatoes and Cucumbers, culture under glass has become much more common, and for obvious reasons. If, however, we refer only to what are common out-of-door vegetables, the principles of cultivation, as well as the details, largely remain the same now as then. It is rather in the direction of variation of products that so marked a change has been made. We have, however, managed pretty well to assist in the survival of the fittest, but myriads of apparently good things have been put into commerce, grown for a few years, then ignored, and finally have entirely vanished from gardens. That such will be the fate of many, even of assumed specially good varieties that figure prominently in seedsman's catalogues now, there can be no doubt. Even if no advance be made, the production of novelties will still go on, but, at least, there is every reason to hope that what development there is will be in the form of improvement, even if it come henceforth very slowly.

It has not been an easy task to obtain any exact presentation of the chief varieties of various vegetables in commerce in 1837. Some useful information has been obtained from various sources, and perhaps the most exact from the *Transactions of the Royal Horticultural Society* during the "thirties," which were then edited by Mr. Knight. That distinguished gardener wrote then with respect to the production of novelties in vegetables in very much the same strain that so many others much more recently have written, but still so uselessly:—"It is seldom that any new vegetables are raised of decided superior quality, and there seems to be no intelligible use in perpetuating kinds whose only merit is that of being different in some trifling particular."

FIG. 153.—THE ORIGINAL PETUNIA, 1837.
(SEE P. 416.)

confined themselves to the showy kinds they liked best, and of each of these they grew large numbers. Then came the opportunity of the professional importer of Orchids, who, seeing that he could find a market for large quantities of each of the showy species, imported many specimens of a few kinds rather than a few specimens of many species, sometimes overdoing the market. But enthusiasm was strong, and a way of equalising matters was soon found, so that while the value of the bulk of ordinary species and varieties depreciated, that of the more rare and extraordinary forms of variable species increased, first in a mild way by doubling or trebling; then, as demand increased, and the supply failed to keep up, with it one hundred pounds, which was thought the highest possible price to be given for a rare variety. The wary shook their heads as they had been doing when big prices were spoken of for the last half-century, and prophesied collapse. But, not a bit of it! The prices for phenomenal varieties still went up, and in our day we hear of two or three hundred pounds being paid for a specimen

What would he have said or written to-day of the varieties had he been alive? If this variation has been trifling in relation to successful varieties, at least in many directions it has been considerable in amount; hence sixty years of raising and selection have left a potent impression on the vegetables of 1897, and we of to-day who grow and consume them are greatly the gainers.

ASPARAGUS

will come first in our review. We have made no great advance in variety, as the old officialis is still the one generally grown. The chief addition has been found in Connover's Colossal and the Purple Argenteuil varieties. But during many years of constant selection with the same variety, much has been done to improve the stock. As a rule now, we neither grow in beds raised high above the surrounding soil, nor allow the plants to remain so long *in situ*. Preferably we plant on the

whilst Johnson's Wonderful and the Seville have been marked additions also; indeed, the latter, under various appellations, has become the most popular garden-Bean of the section. As to culture, here again little difference exists. Runner-Beans, in the early years, included the Scarlet and White Dutch, the Painted Lady, Case-knife, and one or two others of no special merit. Now we grow none of these practically, the scarlet form having been superseded by the better long-podded forms, which may be briefly referred to as of the Ne Plus Ultra type, so that now the pods, produced in exceeding abundance, instead of being short, range from 10 to 12 inches long, and are then tender and edible. Perhaps more of space to the plants is now given, and deeper culture, as well as more ample feeding than was furnished in the early years; yet generally culture remains very much as before. An interesting addition to this section of Beans is found in the carefully-selected runner dwarfs, if

It is interesting to inquire how the appellation "French" became so commonly attached to these Beans. In old days, besides being classed as Haricots, they were called Kidney Beans. It seems sufficient for all purposes now to refer to them as Dwarfs, and to the climbing section as Runners. Generally, with regard to these, culture remains as before.

BEETS

have increased materially in variety, though culture remains to-day much the same. The best variety in 1837 seems to have been the Red Castlenaudry. It would be a rare thing to find that old variety listed now. We have in its place two or three dozen of others, some diverse in form, some only in name; but our best are without doubt first-rate in form, in flesh, and in flavour. Dell's, Nutting's, Dewar's, the Cheltenham Green-top, and a few others constitute the chief types, of which so many are selections. There has been material gain in the introduction of the Egyptian Turnip-rooted, or Blood-red, as through its agency good edible Beetroot may now be obtained much earlier in the summer than was once the case. Whilst we have thus gained in Beets, the ordinary methods of culture have not greatly changed.

BRASSICA.

Broccoli, now spelled with two c's, but formerly with one only, is very much still as it was in '37. True, we have added materially to the number of varieties, especially the late ones; but even then there were some good ones, such as Early White, Knight's Protecting, Brimstone, Miller's Late White, &c.; and the Purple Sprouting. We have added some superior forms, and notably fine late ones, but Broccolis remain still only moderately hardy, and sometimes they are killed wholesale in hard winters. The old growers' methods of culture are very much those of to-day; and valuable as this section of the Brassica family is, it is still, one of the most untrustworthy.

Brussels Sprouts.—Far more certain in usefulness are Brussels Sprouts. About one variety, and that known as the Imported, a good form, too, was cultivated sixty years ago. We have now several, and some excellent selections from the "Imported;" others much stronger in growth, and productive of huge sprouts, are not by all regarded as improvements. However, these strong growers have been largely grown by the market-men in their fields, where the coarser tendencies are materially repressed, with great profit. Generally, the vegetable has changed but little after all.

Cabbages were in variety numerous, at least a dozen varieties being commonly quoted in 1837, we have still Battersea, Vanachi, Early York or Spotborough, Large York, Sugar Leaf, London Market, &c., and of picklers, the Red Dutch. Of these latter, the dwarf Blood-red is especially in gardens a great improvement, not only in compactness but in colour. As to white Cabbages, we now happily are giving much greater preference to these of comparatively small-hearted precocious varieties, of which the popular Elkam's Early is such a good representative, and of which section alone there are many so-called selections in the market. The big Cabbages are now in less favour, but in early and good-sized forms the French Les Etampes has proved to be a capital addition. As to culture nothing fresh is practised, we find

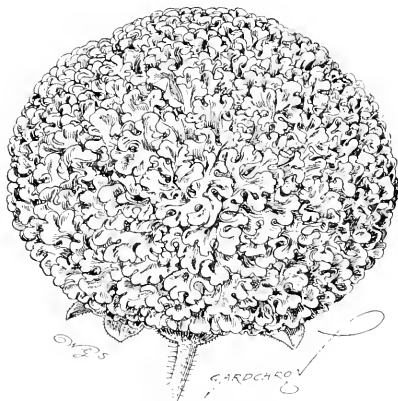

FIG. 160. DOUBLE FETUNIA.

(Exhibited at the Temple Show by Messrs. Sander & Co. See p. 416.)

level, give the plants more room, continue raising some new ones yearly, and making new breadths, so that there is always an annual breadth of established roots to be lifted for winter-foreing; otherwise, in general treatment, culture is not widely dissimilar.

ARTICHOKE (GLOBE).

differ little from the form generally cultivated in the thirties, neither does that culture appreciably vary. Very much may be said of the Jerusalem or tuberosus Artichoke, the exception being the undoubted gain in the introduction of the white-tubered variety. General culture differs little or none.

BEANS,

on the other hand, show marked advance. Of Broad and Longpod forms, the old Green Windsor is still one of the best, as it was in 1837; and of Longpods we still have the Early Green and the Dutch, with the Dwarf Fan-cluster. But of the latter, Beck's Green Gem is an improvement undoubtedly;

they may be so described, that well-known variety, Canadian Wonder, having developed such climbing tendencies that these have been utilised to constitute a separate section of smooth-podded runners. The Butter Beans, also, have become materially popularised of late, and, once ignored, now are found in many gardens, where their delicious pods find appreciation.

Of dwarf Beans, invariably in the thirties termed "Haricots," probably at first more grown for their ripe seed than for their tender pods, the best known were Early Cream, Early Purple-speckled, and the Negro. We have many varieties now, but except for early forcing, where very dwarf varieties are grown, the general best of to-day, whether for late forcing in pots or for outdoor culture are Osborne's Forcing Ne Plus Ultra, the Long-podded Negro, and Canadian Wonder. These latter three are, perhaps, more widely grown than are any others. They are all so good as to be difficult to excel, in spite of the frequent introduction of other forms.

no better practices than were those of our forefathers.

Cauliflowers.—In the case of this kind of vegetable, a most important one, some material progression is evident. In the thirties, the most commonly grown were Early London, necessarily wintered in frames or under hand-lights, to have early heads; and Walcheren, whilst the large Asiatic and Purple Cape were autumn forms. Now we have that early dwarf form, of which the early Snowball is the type, and which can be induced to head-in from January sowings under glass, sooner than the autumn-sown "London" would do, and may even be grown in frames or in pits, with moderate gain. Then for autumn purposes, the fine Autumn Giant and its selections have proved to be splendid additions to our stocks, so that in gardens or in fields the Cauliflower can be had over a long autumn in great abundance, and the heads are so cheap as to be accessible to the poorest when in season. Our chief cultural change is found now in sowing less in the autumn for wintering, and in raising the more precocious varieties from seed under glass early in the year, planting out later comparatively close together on warm borders.

(To be continued.)

PETUNIAS, 1837—1897.

AMONG the great and stirring events we are now commemorating in connection with the accession of Her Majesty in 1837, it is not without interest to horticulturists to recall that in that year the first hybrid Petunia was brought out. *P. violacea* (purple) and *P. nyctaginiflora* (white) had been introduced some years previously, but their flowers were inconspicuous as compared with those of the first hybrid, and more especially in comparison with the gigantic varieties we now have. These are the result, in the first instance, of the combination of the two species above named. Contrary to what happens in some hybrids, the Petunia hybrids are as fertile as the species themselves. Moreover, they intercross freely, and thus we have obtained the great variety which now decorate our gardens and houses. Our figure of the original florist's Petunia was taken from the *Botanical Magazine* (1837), t. 3556. It is curious to read now the comment of the editor. "It must be confessed that here, as in many other vegetable productions, the art and skill of the horticulturist has improved nature. Cultivation alone has, indeed, very much increased the size of the flowers and foliage of this plant, so that it can scarcely be recognised as belonging to the same species as the native specimens sent by Mr. Tweedie." [What then is it now? Ed.] Fig. 160 is a representation of a double rosy lilac-coloured variety, exhibited at the Temple Show by Messrs. Sander, of St. Albans. The single variety shown at fig. 161, is from a bloom obligingly furnished us by Messrs. Jas. Carter of Iligh Holborn, whose strain of these plants is in deservedly high repute. Large as it is, it is not so large as some that have been produced. The doubled condition generally arises from the substitution of petals for stamens, and sometimes from the multiplication or increased number of the petals themselves, as in Messrs. Sander's Petunia. In some forms the margin of the corolla is green and leaf-like, the other portions being of a violet hue; in this variety the stamens are also frequently replaced by leaves, the filament of the stamen answering to the stalk of the leaf, while the anther is replaced by the blade.

NEW OR NOTEWORTHY PLANTS.

DENDROBIUM PAPILIO, n. sp., Lohrer.*

A CHARMING species of the crumenatum group. Its large, solitary, pale rose-coloured flowers hang down from their thin, grass-like stems in great profusion, resembling butterflies suspended in the air. The sepals and petals of the nearly 2-inch-wide flowers are ovate, and the broad, undulated lip is long, stipitate, with a few purple veins. The fragrant flowers last only one or two days. *A. Lohrer, Manila.*

ORCHID NOTES AND GLEANINGS.

LELIA PURPURATA FASTUOSA, WARBURTON'S VAR.

AMONG the *Lelia purpurata* of recent importation have cropped up some extra dark varieties, in which the segments approach in hue the high colour of the lip the writer described in the *Gardener's Chronicle* of 1896, vol. xix., and to that supplementary description, illustrated, July 11 the same year, vol. xx., of the wonderful *Lelia purpurata* Ashworthiana, with petals as broad as those of a fair-sized Cattleya, and with a lip of surpassing brilliancy. That variety was staged at the Temple Show of this year, and received, as it deserved to do, a First-class Certificate. The one now under notice was also shown, and received an Award of Merit. They are both prime varieties, as novel as they are beautiful, and each distinct from each. Mr. Ashworth's plant was imported by Cowan & Co., Garston; Mr. Warburton's came from the Messrs. Linden, Brussels. Having the best opportunities of seeing both the varieties in the height of floral beauty, I now append a description of the fine prize variety:—

Sepals as in the normal form of the species, flamed on a lightish ground; petals, $\frac{1}{2}$ inches breadth; length of each, $\frac{3}{4}$ inches; with $\frac{1}{2}$ across the flower touching 7 inches; highly flamed from the median rib, with numerous radiating Peach-coloured veins. These limbs do not stand out so flat as in Ashworthiana—indeed, they are screwed up, not unlike a *Sarracenia* pitcher, and in this respect spelling the appearance of the flower. The lip is something magnificent, superior in colour to the variety to which we compare it. It is 3 inches long from base to extremity, the convolute portion being $\frac{1}{2}$ inch, and the expanded portion, or the blade, is also $\frac{1}{2}$ inch, and the diameter of the lip is 2 inches. The blade is a marvel of brilliant amethyst colour, nearly solid, and forms a sweeping ovate outline. The convolute portion is of a captivating ruddy shade, broadly margined with white, into which the red lines disappear. The back of the lip is as conspicuous as the front, the whole showing great substance. The column is less convex than the normal form, and the pollinia are white.

CATTELEYA SUPERBA.

AFTER all the ups and downs of the history of the cultivation of *Cattleya superba*, one is glad to chronicle the well doing of a score of plants in one of the little houses of D. B. Rappart, Esq., the Promenade, Lisard, Cheshire (Mr. Nicholson, gr.). The original batches imported a quarter of a century and longer ago have all disappeared, growing less and less every year under culture. Mr. Bewley of Dublin thought he had mastered their cultivation when he tied them to large blocks of hard wood, and put them under double-glass roofs. He enamoured even the late James Veitch, who told me

* *Dendrobium Papilio*, n. sp.—Elobis, exspisum, subpendulum, ramosissimum; ramulis tenuibus; folia e basi auriculata linearia, $\frac{1}{2}$ -2 pollicaria, vaginis viridis purpureis. Flores in apice ramulorum ciliatorum solitarii, squiter 2 pollicares, penduli, calice pallide roseo, latis albis, sepalis petalisque subaequalibus ovatis, orbis sensim filice, subrevolutis. Labellum longe unguiculatum, stipite candelato flavo, limbo rotundato emarginato-undulato, striis tribus et nervis lateribus purpureis; columna apice bicornuta, alba, antice utrinque lineis hauri purpureis. Ins. 4. Lohr.

he sent over the late Zadok Stevens and John Dominy to see for themselves. They reported more than favourably of it, and the consequence was that double glass roofs at Chelsea was the order of the day, until it was found out that they did more harm than good, particularly in summer, and off they had to come. The plants in question at Lisard are suspended in low-roofed houses, mostly in baskets, and they are in the pink of health, and showing nearly every one of their sheaths, some advancing into flower. The roots are seeking their way through the partitioned chip-baskets, and the leaves are strong and healthy. Up to now, the young bulbs are increasing in bulk, and we look forward to secure some of them before either of the Orchid committees. The climate on the banks of the Mersey is an excellent one, the moisture being agreeable, and the temperature encouraging, which may account for the satisfactory state of growth up to now—will it last? *J. Anderson.*

THE ROSARY.

HYBRID TEA ROSES.

SOME years ago it was decided by the National Rose Society that several varieties of considerable importance, previously denominated hybrid perpetuals, should thenceforth be regarded as hybrid Teas. This class has of late years been materially enlarged by contributions from the rosarians of Britain, Germany, and France. Among the more valuable introductions for which we are indebted to the French raisers are *Gustave Rejis*, not long since highly spoken of by "Wild Rose" in this journal for the beauty of its buds, though he indicated its limitations when fully blown; *Madame Fernet Ducher*, cary yellow in colour, with a deeper shading in the centre—a Rose of great decorative capability, which I cannot but regard as one of the finest of the hybrid Teas; *Marquis of Salisbury*, also a very abundant bloomer, of brilliant scarlet hue; *Marquis Litta*, a Rose of vigorous growth, with large flowers of carmine-pink complexion, generally accounted an improvement upon its immediate predecessor, *La Fraicheur*; and *Caroline Testout*, which is equally, in my opinion, an advance upon *La France*—being alike in form and in colour, decidedly superior to the parent Rose. The latter, however, still retains its immense popularity; and it must always remain, by reason of its sweetness, supremely attractive. *Augustine Guineoisseau* has been called somewhat erroneously, a "white La France"; but, though it greatly resembles its parent in everything save colour, its hue is not an absolute white, being most decidedly suffused with rose. It is, however, the nearest approximation to the ideal so much desiderated, that has yet been found. Among other highly popular French hybrid Teas is *Charlotte Guillemet*, a variety of great promise, which I had in flower in my garden for the first time last year, but which, though described in the catalogues as very free-flowering, did not produce too many of its beautiful ivory-white blooms; and *Bardou Job*, raised by Nabonnand in 1887, of very vivid crimson complexion, but only semi-double, though this limitation does not affect its great value for artistic and decorative effect. *Gloire Lyonnaise*, one of the most beautiful productions of the late M. Guillot, of Lyons, to whom we are indebted for many other varieties of equal value and renown, is of considerably older date than those already characterised; but not so venerable as *Captain Christy*, which was introduced contemporaneously with the English *Cheshunt Hybrid* by M. Lacharme in 1873.

Grand Duc A. de Luxembourg and Souvenir de Madame Eugénie Verdier are meritorious French Roses of recent introduction. *Kaiserin Augusta Victoria* is a German Hybrid Tea of the highest merit; its colour, pale primrose, is very fascinating, and its flowers have the substance of *Souvenir de la Malmaison* or *Gloire de Dijon*. This is undoubtedly the great acquisition; among modern Roses of its special class, the one most likely, by reason of its commanding attributes, to endure.

Of British hybrid Teas, the most important are Viscountess Folkestone, Lady Mary Fitzwilliam, whose chief limitation is its indifferent growth, though it makes some compensation in the dimensions of its imposing and richly-fragrant flowers; Lady Henry Grosvenor and Clara Watson, associated with the memory of Mr. Henry Bennet; Chesnut Hybrid, a climbing Rose of great merit, remarkable alike for its fragrance, vigour of growth, and great productiveness; Duchess of Albany, a dark La France; Princess May, a charming pink hybrid, between Gloire de Dijon and another variety possessing a colour more akin to its own; the White Lady, a beautiful daughter of Lady Mary Fitzwilliam; and those ema-

HOME CORRESPONDENCE.

ROSES.—I strongly hold that any article, however sketchy, upon Roses originated during the reign of Victoria, without some reference to the originators of such varieties as *Moden*, the grandest Tea Rose Britain has produced; *Mrs. Paul*, the noblest of the Bourbon family; *Duke of Albany*, the most impressive in its colouring, fullness, and exquisite imbrication of all the dark, velvety-crimson hybrid perpetuals; *Queen Mab*, the most brilliantly-coloured of the Chinas; *Pride of Waltham*, indispensable for exhibition; *Carmine Pillar*, the most decorative single Rose of the last decade that England has given us; *Olo*, *Spenser*, *Echautress*, and *Empress Alex-*

Herts, *Oxford*, and *Cambridge*. Owing to the coolness of the previous night, and the stormy character of the exhibition-day, the blooms stood remarkably well, and were, as a rule, as fresh late in the afternoon as when staged in the morning. *E. M., Berchamsted.*

GARDEN PINKS.—A very marked feature of the newer race of garden Pinks is found in their tendency to bloom freely in the autumn. This is especially the case with young plants from previous season's pipings, carrying few flowers in June, but heads of bloom in September, when Pink flowers are just as acceptable as at any time. Garden Pinks have suffered a good deal in reputation because they have been in relation to culture rather neglected than cared for. It is important, to see them in their best form, that pipings be inserted in sandy soil, either under handlights or beneath a north wall early in July. A few scores so set in assures almost absolutely numerous plants to go out into the borders in the autumn, and these flowering moderately the following summer, do so well in the autumn, and then, having become broad clumps, flower most profusely the following year. After that, they may be destroyed, or if there has been a failure with the pipings then lifted, pulled to pieces, and replanted in October, they soon become established plants again. Whilst our old border Pinks, white and pink in colour, are far too common alone in gardens, *Mrs. Sinkins* and *Her Majesty*, though the flowers are large, are yet very ugly, because the pods often burst, and the petals become a mass of loose rags. Far better are the old *Paddington*, a pretty red Pink, the pure white *Snowflake*, and *Albinos*, our best of this hue, and the many seedling varieties, named and unnamed, in various colours, *Mr. B. Ladham* and *Mr. R. Deau* have raised and put into commerce. Such flowers are deliciously perfumed, and are pleasing for bouqueting, but as garden plants the beauty is most evident in a growing state. A garden set apart for Pinks exclusively might now be made a striking feature in any good place. *A. L.*

FIG. 161.—A MODERN PETUNIA.

(From a specimen sent by Messrs. James Carter & Co. See p. 416.)

nations from Newtownards of the greatest attractiveness, one of them a Gold Medallist of the National Rose Society, *Marjorie*, and *Mrs. W. J. Grant*—of which the former is a Rose of the sweetest and gentlest description, though not of remarkably robust growth; while the latter inherits the finest attributes of *La France*.

The hybrid Tea Roses require no eulogium; in any representative garden where they are adequately and extensively cultivated, they can speak for themselves. In them may be found the strength and majesty of the hybrid perpetuals, combined with the delicate fragrance and graceful foliage of the Teas. They are, therefore, invaluable for garden cultivation. *David R. Williamson.*

andra of Russia, is not likely to be accounted adequate by men whose achievements have been such as these. *W.*

THE PORTSMOUTH ROSE SHOW.—A few particulars respecting the show held by the National Rose Society at Portsmouth on the 18th inst., may be of interest, as it took place at an earlier date than any previous exhibition of the Society. The total number of blooms staged in competition was 1060, or a smaller number than at any other National Rose Society show yet held. In this calculation no account is taken of the beautiful display of garden Roses at this or previous shows. There were in all thirty-seven exhibitors who came from the following counties:—Devon, Dorset, Somerset, Haunts (including Isle of Wight), Kent, Surrey, Essex, Bucks,

DIAMOND JUBILEE SPECIALS.—It was a happy thought on the part of Mr. Edwin Poole, head-gardener to *Lady Cave*, *Cleve Hill*, *Downend*, near *Bristol*, to commemorate *Her Majesty's* reign by himself collecting the wherewithal cash and credit to enable him to add twenty-two classes of "Diamond Jubilee Specials" to the schedule of the local flower show, there being from three to four prizes offered in each class, these varying in value from 10s. downwards, and to be competed for by bona fide agricultural labourers, being members of the Mangotsfield branch of the N. A. U. The "specials" include prizes for collections of vegetables, of window-grown plants, of table-Ferns, of ornamental foliage-plants, &c. A silver medal being given by *O. Graham, Esq.*, for the best collection of vegetables, fruit, and flowers, set up with an eye to effect. Prizes are also offered for bouquets, sprays, Roses, allotments, &c. In a few classes, the 2d, 3rd, and 4th prizes consist of garden tools. *H. W. W.*

REDUCING THE HEIGHT OF TALL TREE-FERNS.—I am obliged to Mr. Fletcher for his remarks on this subject. As, however, circumstances vary, everyone must judge for himself as to the best and quickest method to be adopted in his particular case. According to Mr. Fletcher, he cuts 12 inches off the bottom of his *Alsophila Moorei* every second year, and also adds that it grows as luxuriantly as ever. If after making allowance for two years' growth, surely there cannot be much reduction in height. It was desired to reduce the height of the Fern I wrote of—*Cyathea medullaris*—9 to 10 feet. This was managed by sinking the top of the ball a foot or so in the ground when replanting. But I fear that had we adopted Mr. Fletcher's 6 inches per annum method, we should find life too short for the end to be attained. As I said before, we placed the box 7 feet up the stem, and as few or no roots were visible at this part of the stem, we had to wait for them to grow. Clumsy the method adopted may have been, but as to its being unsightly, surely a little ingenuity might render a neatly-made and painted box not so very much more unsightly than one lower down, i.e., on the floor. The box in question was almost entirely hid by the growth of other Ferns, &c. *Edw. Barter.* [We think that our correspondent shows good cause for his method. Ed.]

LATE BROCCOLI.—In our late district, the variety *Sutton's Late Queen* has never failed with us to produce good heads till late in the present month. I am cutting daily nice heads, which may be served at

table whole, from plants raised from three-year-old seed sown about the middle of the month of May, 1896. My stock of plants of the present year are from the same batch of seed, now four years old, which came up very thickly from a sowing made on May 11. I have seed of the same age for trial next year. There is variety in the leaf, some being more curly than others; and the heads keep turning in for three weeks or longer. I cut the first on June 2, which was ten days later than last year. The habit is leaf as I grow them, that is, on firm ground. This variety of Broccoli is one of the greatest helps that a gardener without appliances can have for bringing on early Cauliflowers—at least, I find it so. *George Bates.*

PLANTS OF THE VICTORIAN ERA.

HARDY TREES AND SHRUBS.

(Continued from p. 390.)

AMONG trees and shrubs we have also a large number deserving notice as valuable additions to our parks and shrubberies; and taking them alphabetically, the first place must be given to the Aucuba, for although the common "Spotted Laurel," as it is generally called, came to us as early as 1783, it was only the female plant, and it was left to Robert Fortune to send us the first males. The well-known Aucuba is maculated with yellow, going, as it were, into oriental mourning for its husband, which, as he did not appear in Europe till more than half a century had elapsed, she might well have given up as lost. Next, we have another Japanese shrub, the Azalea mollis, flowering freely, with exceptionally rich and brilliant coloured trusses of flower, whose only fault is that they are so very short-lived.

Ceanothus azureus and Escallonia rubra and macrantha were also introduced to commerce in the early part of the reign, the former having been greatly improved by the hybridists, the variety, Gloire de Versailles, being among the finest, but both unfortunately are restricted to the southern and western shores of our country, as they are not perfectly hardy.

The interesting Clematis (*Atrageae*) coccinea has but lately come to us, and except for its novel colour in that genus, need not be included here, but Messrs. Jackman have taken it in hand, and we have, as a result, three novelties in which the prevailing colour is scarlet or bright pink, foreshadowing many interesting possibilities for the hybridist. In 1844 we were enriched by the introduction of Weigela rosea, the parent of a number of pleasing varieties, which give us their flowers in May and June, and range in colour from bright pink to deep maroon red, while the pure white form, though more tender (*W. hortensis nivea*) is both an excellent pot-plant to force and a desirable shrub for a sheltered border. The first Deutzia, *D. scabra*, was brought to Britain some years (1833) before Queen Victoria was crowned, but we have since received the species *D. gracilis* and *D. crenata*, and many hybrids from Lemoine, all very useful shrubs, either for the borders or for forcing; all are interesting to the owners of a microscope even of modest power, as the leaf has beautiful stellate hairs on the upper surface, which, by reflected light, look like frosted silver stars against the bright green colour of the leaf. In 1838 was sent us the grand foliaged *Aralia japonica* to enrich our shrubberies and lawns; while we had the *Elaeagnus*, but since then from Japan many finer varieties through Von Siebold and Veitch. A Japanese shrub, now quite indispensable in gardens near the sea, though unfortunately not hardy inland, is the *Euonymus japonicus*, this was introduced in 1831, but was not sold

in nurseries till some years later, and therefore must rank among our Jubilee gems; the later varieties, "ovata," and its gold and silver variegated sports making most useful pot-plants or shrubs for window decoration, which may be said to have originated in the last twenty years of the present reign, and which may be claimed as totally altering the appearance of our squares and streets since its almost universal adoption. I must, however, only allude to many choice and useful acquisitions of the period, viz., *Cytisus scoparius* var. *Andreaus*, the unique and exceedingly useful *Hydrangea paniculata grandiflora*, and *H. hortensis alba* "Dr. Hogg;" and among the very latest novelties in this genus the *H. japonica* var. exhibited by Messrs. J. Veitch & Sons at the Temple Show, bearing barren flowers after its kind, nearly if not quite 2 inches in diameter, and so bright a shade of rose as to closely approach scarlet.

Among the leading attractions of the grand Temple Show, May 26 to 28, were the hardy shrubs new to commerce, staged by Messrs. J. Veitch & Son, of Chelsea, and Fisher Holmes & Co. of Sheffield, the Japanese Maples in all their elegant and varied forms, making a chaste groundwork; other good things being *Cytisus procerus* and *Olearia stellaris*, with its masses of white-scented flowers contrasting well with the stiff and erect growth of *Clethra alnifolia*; a good new Weigela *Eva Ratke*, and some good examples of a new *Andromeda speciosa cassinifolia* with wax-like flowers, while some hybrid *Azalea sinensis* x *Mollis* showed the great field open to the hybridist in this direction. Messrs. Fisher Holmes also used Japanese Maples freely—would that they were quite hardy! and also staged the variegated form of *Rubus fruticosus*, and a new Japanese variegated *Andromeda*, with a good Elder, *Sambucus racemosa plumosa aurea*, all of which plants are worthy of the Jubilee year; while a Dogwood called *Cornus Späthii*, with golden variegated leaves, was most attractive, and said to be the best variegated leaved plant for the North, and more hardy than the useful *Acer Negundo* variegatum.

Nor must the Tree Ivy be omitted, as they originated during the period 1887-1897, and now are great in variety, and most useful for winter-bedding.

The Laurel, most useful among evergreen shrubs, has been wonderfully improved, one vigorous and hardy novelty being *Prunus laurocerasus* var. *caucasicus*; while the round-leaved form, *P. laurocerasus rotundifolius*, has at once leaped to eminence; and the Portugal Laurel has given us a fine variety in "myrtifolia," known in English nurseries as Knight's pyramidal form; and the deservedly admired, but somewhat tender, *Laurustinus* (*Viburnum Tinus*) has given us a grand seedling sport in "hirsutus," or nigrescens of the Continental nurseries, for it is not only more vigorous and erect in growth, but the panicles of flowers are larger, while it is more hardy. The Privet, too, has given us a grand acquisition in *Ligustrum ovalifolium*, no plant making a quicker or better evergreen hedge, while its golden variegated form will lend variety and colour to our shrubberies. All succeed in the smoke of towns and cities, as well as in exposed positions by the seaside. Japan has also contributed some useful species, among which the leathery-leaved Privet, *L. coriaceum*, is the most distinct.

Both the green-leaved and golden variegated-leaved evergreen Honeyuckles, as they are

popularly called, *L. brachypoda* and *L. b. aurea reticulata*, are plants of the period we are now commemorating, both hailing from Japan, though natives of China; while the brilliant scarlet trumpet Honeyuckle was introduced from Carolina, in the time of Cromwell, who, as it might be surmised, was but a poor encourager of the gardener's art. *Experience.*

(To be continued.)

THE WEEK'S WORK.

THE ORCHID HOUSES.

By W. H. WATTS, Orchid Grower, Burford, Dorset.

Cymbidium Devonianum, now making growths, should be raised up to the light in the intermediate-house, and be afforded plenty of water at the root till growth is finished.

Leptotes.—When well flowered, *Leptotes bicolor* forms a pretty object in the Cattleya house, and the plant will now be starting to make roots freely. It is a species which resents having its roots disturbed at any time, and repotting sometimes causes the plant to deteriorate. If the rhizomes have grown over the edges of the pan or basket, and the roots cling to the latter, do not interfere with them in any way, but pick out the decayed potting materials, and substitute fresh, hanging the plant in a light part of the Cattleya house, and affording copious waterings each time the compost becomes quite dry.

Dendrobium Brymerianum and *D. cymbiloides* appear to thrive best in the Cattleya-house, and both are species that now begin to make growth; they may be repotted at this season. The former does best in a pot stood upon the stage with the Cattleyas, the latter in a shallow, perforated pan, or in a basket hung close to the roof. *D. macrophyllum* Richardi variety, and *D. tr.* *Vetichianum*, succeed under a similar kind of treatment as *D. cymbiloides*. The singular-looking *D. Cœlogyne* should be hung near the roof of a house having a temperature intermediate between that of the Cattleya and the *Odontoglossum*-houses.

Cœlogyne data and others.—This species will now be making roots. These come from the base of the newly-started growth, and if repotting is necessary, it should be done at once. Owing to its rambling habit, it is useless to try and make the plant conform to cultivation in an *Orchid-pot*; but it will succeed in a long and narrow *Teak* basket, rooting freely in peat and sphagnum-moss. The plant may also be fastened to a long piece of *Tree-Fern* stem, where it will do well. The plant is at home at all seasons in a moist, shady part of the intermediate-house. As regards water, the plant requires an abundance during the season of growth, but at other seasons it suffices if the compost be kept just merely moist. Other *Cœlogynes* which require a similar cultural treatment, but which grow well in pots, are *C. Rossiana*, *C. speciosa*, *C. glandulosa*, *C. graminifolia*, *C. corrugata*, *C. corymbosa*, *C. Cumingi*, *C. barbata*, and *C. conferta*. *C. acellata* grows best in the coolest part of the house. Such dwarf-growing varieties as *C. odoratissima*, *C. sparsa*, and *C. firmibata* should be planted in shallow pans suspended to the roof. *C. flaccida*, *C. Dayana*, and others, which produce long, pendulous flower-scapes, may be hung high. *C. Massangena*, *C. tomentosa*, *C. asperata*, and *C. pandurata* require the warm, moist condition of the East India-house or ordinary stove. The fragrant *C. ochracea* grows and flowers well if placed at the warmer part of the cool-house. Plants of *C. cristata* and its varieties, *C. c. maxima*, *Lemoniana*, *Chatsworth*, and *hololeuca* (alba), if they were repotted at the proper time, will now be re-established, and the amount of water afforded at the root may be gradually increased, continuing to lightly dose the leaves at closing time.

FRUITS UNDER GLASS.

By F. HANSEN, Gardener, Eastnor Castle, Leicestershire.

Early Peach-house.—As soon as the fruit has been cleared from this house, cut out all the old bearing wood and other superfluous shoots from the trees, leaving sufficient only to cover the trellis for next year's crop. Tie up any loose shoots, and if any signs of fly or red-spider are observed, give the trees a good syringing after sunset over and under with

strong soft-soap, or a safe insecticide. The following morning a good washing with clean water will be necessary. If the lights are movable, take them off and store in a safe place, but if they are not, afford every possible means of ventilation. Be careful to provide the roots with sufficient moisture.

Succession Houses.—Where fruit is ripening keep the atmosphere rather cooler and drier by ventilation. Expose each fruit as far as possible to the sun, and if the borders are at all dry, give a moderate quantity of tepid-water. Too much moisture at the roots when the fruit is approaching ripeness may cause it to crack. In houses where the fruit is commencing its last swelling, and the trees are carrying a good crop, afford liberal supplies of liquid-manure. Examine trees where the fruit has finished stoning, and if the crop is too heavy, remove a few of the smallest fruits. It is advisable during early thinnings to leave a few extra fruits on such varieties as the Prince of Wales, which, in this locality, is liable to cast part of its fruit when stoning; Stanwick Elvage Nectarine is another. Remove all lateral growth, and secure others by tying, and take care that the fruit is well propped up to the light as soon as possible. Later houses should be kept as cool as possible, to prolong the succession. Give abundant supplies of water, and thin out the fruits a few at a time until the required quantity is left. Use the syringes frequently in all these houses until the fruit commences to colour, but avoid morning-syringing in hot localities, especially in the case of Nectarines, for if hot sun gets on them when the fruit is wet, rust is almost sure to ensue. From this time onwards we discontinue morning syringing, and give a good deluging in the afternoon at closing time.

THE FLOWER GARDEN.

By CHARLES HERRIN, Gardener, Dropponi, Maidenhead.

Clematis.—Clematis of the Jackmanni type should have the shoots nailed up, or tied where trailed to arches, &c., as often as necessary, to prevent the shoots breaking down or becoming entangled. The early-flowering species of Clematis, as *C. montana*, have now mostly passed the flowering period, and if pruning is necessary, it should now be done, as the new growths for next spring will be the flowering shoots of next spring. In the case of old plants of *C. montana* that have become a thicket of shoots, the best plan is to prune severely to the old wood, and cut all the small shoots right away. Loniceras, climbing Roses, Wistarias, and other climbers, making long and strong growths, will need to have the shoots tied in or nailed, as the case may be.

Violets.—The recent rains have been of much assistance in establishing newly-planted Violet-runners and divisions, and hand-weeding will be required to keep them free from weeds. A thin mulch of leaf-soil or old Mushroom-bed manure will assist in retaining moisture, and encourage a free growth in the plants. When the foliage assumes a yellow tint, it is an almost sure indication of the presence of red-spider, and a thorough syringing, such as will reach the under part of the foliage, should be given, with a solution of Gishurst Compound, or similar dressing, repeating the operation at intervals of a day or two until the pest is eradicated.

General Work.—Bedding out will now be mostly finished, and any work that has been perforce neglected during this busy season should now receive due attention. A general clean-up of the flower-garden and borders should be given precedence. Where a mulching has not been applied to flower-beds, a stirring of the surface soil with a small hoe will assist in promoting a free growth, and keep down small weeds. Remove any dead or decaying leaves and blooms. Peg down Verbenas so as to cover the soil as far as possible. African Marigolds, either in beds or borders, may be topped, to induce a more bushy habit. Lawes require to be mown weekly, and grass edges to walks should be kept closely clipped and the paths clean.

PLANTS UNDER GLASS.

By G. H. MAYCOCK, Gardener, Luton Hoop Park, Luton.

Chrysanthemums.—If these plants are not yet placed in their summer quarters, no time should be lost in getting this done, selecting an open position in the garden where to stand them. It is a safe plan to drive in some stout stakes in lines 5 to 6 feet apart, securing to these two lengths of stout iron wire at 2 feet and 4 feet from the ground, and fasten to these wires the stakes which support the stems of the plants. Beneath the pots place coal-ashes 1 inch deep, and a piece of slate under the central hole in

each pot. To simplify things, the varieties should be arranged in groups together. Those intended for the production of show blooms should be staked with Bamboo-rod forthwith. After very bright sunny days, the plants are much benefited by receiving at about 5 P.M. a good syringing, and all of the collection should be examined three times daily to ascertain if water is required. Attention should be given to the securing of aphids on the foliage apply tobacco-powder late in the afternoon, syringing it off the foliage next morning.

Calceolarias.—A first sowing of seed of the herbaceous section may now be made, another taking place about the third week in July. It is important that only seed from the best strains should be sown, and in sowing a good deal of care is necessary. As the young plants readily damp off, good drainage is of importance, especially in the early stages of growth. The seed-pans should be 3 inches deep, well drained, the cracks being covered with a layer of half-decayed leaves, and on this a mixture consisting of leaf-mould one-third, good fibry loam one-third, and sand and rotten cow-manure in a dry state one-third, well mixed together and then finely sifted, pressing with moderate firmness. Scatter the seeds thinly over the surface, and just cover them, and no more, with soil and sand passed through a very fine-meshed sieve. If the soil be moist, i.e., neither too wet or too dry, no water need be afforded till some days after sowing, or even not until the plants appear; place the pans on inverted pots in a cold frame, set facing north, with a high wall on the south side. Keep a sharp look out for slugs; do not let the plants suffer from drought; afford air as soon as the plants push through the soil, but do not err in admitting so great a quantity that the frame is neither too hot nor too cold, and muggy, or damping off will happen; and do not let the sun, when it is powerful, shine upon them.

THE KITCHEN GARDEN.

By W. POPE, Gardener, Highclere Castle, Newbury.

Tomatoes Out-of-doors.—Remove every one of the side-shoots from the plants, and secure the latter to the wall or fence with broad strands of bast or long shreds; and if the plants are growing away from a wall and against stakes, see that the latter are stout ones, of at the least 4 1/2 feet of their height out of the ground and 1 1/2 deep in it. When three or four clusters of fruit have set, nip out the leading point. Afford water freely, and manure-water occasionally when the fruit is swelling if the weather be warm and dry.

Parsley.—When the leaves of the spring-sown Parsley are fit for gathering, clear the ground of the old crop of plants now running to seed, for they greatly exhaust the soil. Whilst the soil is left from rain, thinnings of Parsley may be dibbled in rows 1 foot apart, and half the distance between the plants into beds or borders of rich soil. When rain is in this condition, it is a capital time to make another sowing for coming into use in the winter and later. This last sowing does not usually run to seed early in the succeeding summer. Fresh soil forms a good sort of dressing for the land when sowing the seed, and occasional dressings are beneficial to the plants.

Celery.—Continue to plant Celery in trenches, securing a good ball of soil with each plant, and inserting each firmly with a trowel. Plants already established should be afforded manure-water in liberal quantity occasionally, alternating these with applications of plain water. Never let Celery lack moisture at the root, nor hurry the earthing-up, but let the heart-leaves of the plants come up unchecked, and the latter acquire size before this is commenced. Preparatory to earthing-up, tie the outer leaves loosely together; this is also a protection against wind. Apply a light mulch of rotten manure over the roots. Celery for exhibition may be blanched by wrapping it in several thicknesses of brown paper for about five weeks or a little longer in the cooler months of autumn. This method of blanching has the advantage of keeping the sticks clean; moreover, water can be applied at the root to the last, which is an important point, but one that it is impossible to carry out when Celery is earthing-up in the usual method.

Leeks for Exhibition require much the same kind of treatment as Celery, except that it is best to earth-up the stems gradually, say, at fortnightly intervals. Liquid manure should be copiously supplied to Leeks, the plants reveling in rich foods.

Cauliflowers.—A good breadth of Cauliflowers may now be planted for the autumn supply, and advancing crops may be afforded liquid-manure if very large and close heads are wanted; but for ordinary uses, a fairly rich soil will produce them of sufficient size without such aids. The land under young plantations of the plants should be dressed with fresh soil and powdered quick-lime, or slugs may destroy the hearts.

THE HARDY FRUIT GARDEN.

By H. W. WARD, Rayleigh, Essex.

The Preparation of the Land on which it is intended to plant Strawberries in August should be undertaken as soon after this date as possible, to allow of it setting and getting consolidated before it is planted. Land which has carried crops of Spinach, late Broccoli, Cauliflowers, Turnips, or Peas, will suit admirably for Strawberries. In order to secure good and abundant crops of fruit, the land should be trenched from 18 to 20 inches deep according to the depth of the tith, two or three thickish layers of short-manure being worked in whilst trenching it. If the bottom spit consists of comparatively poor soil, loosen it with digging-fork, and dress it with manure, but leave it in position. If the required runners be layered forth with pots 6 or 8 to the case, filled with peaty-soil, time will be saved in establishing them, there being little or no check given the plants when setting them out. In dry weather the layers should be watered overhead daily. Royal Sovereign, Sir Joseph Paxton, Auguste Nicaise, British Queen, Guntton Park, Helena Gloede (late), and Oxonian (late), are seven varieties which it would be difficult to beat for cropping, size of berry, and flavour. It is a matter of importance that the plants of layered runners be kept from extending by nipping their shoots out. If those plants which have been forced have received proper attention since they were removed from the forcing-houses, they may also be planted out on similarly prepared land as that intended to be planted with layers, and they will yield good crops of fruit next year. Plants of the early varieties from which the fruit was gathered in March produce ripe fruits in August and September, but to do this they should be planted out early in May. Mulchings of dung benefit these plants greatly. These forced plants in favourable seasons produce fruit in some abundance, filling up a void in the supply of soft fruit, and being themselves succeeded by the alpine Strawberry, which bears fruit till the frosts come.

THE APIARY.

By EXPERT.

Artificial Honey.—At a recent meeting of the Victoria Beekeeper's Association, at which the members discussed the subject of imitation honey, which is said to be "flooding the Melbourne market," Mr. Field, a practical chemist, gave an account of some analyses he had made of samples of both pure honey and this imitation. He showed the members a simple method of testing what is pure and what manufactured honey, by adding a little pure alcohol to honey or its imitation dissolved in an equal volume of water. This solution, on being shaken up with alcohol remained nearly clear and limpid in the case of honey, but in the case of the imitation it at once became opaque like dirty milk, due to the deposition of dextrose from the starch-sugar. Mr. Field stated that the samples were made from corn-syrup or starch-sugar, a cheap, crude material obtained from Potatoes and sulphuric acid, or from maize, or even rags and dextrose, and was the principal constituent of the samples of manufactured honey he had examined. The chairman stated he had examined several samples with the polariscope, by which means the fraud was easily detected. *Farming World.*

A NEW ALPINE GARDEN.—We learn from Turin that on August 1 next the alpine garden, named La Chauxoia, will be duly inaugurated on the Little St. Bernard. The name of the garden is taken from that of the rector of the Hospice, the Abbe CHANOUX. The secretary of the committee is SIGNORE LUIGI GIORDIO BONELLI, and the work is carried out under the auspices of the Alpine Club of Turin. The main object of the garden is to secure protection for the rarer alpine plants, and to prevent their extermination.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on ONE SIDE ONLY of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY,	JUNE 26	Windsor Horticultural and Rose, (1) Windsor Horticultural and Rose, at Drill Hall.
TUESDAY,	JUNE 29	Royal Horticultural Society, at Royal Oxfordshire Horticultural Society, Commemoration Show, Hereford and West of England Rose Society. Ross Shows at Canterbury and Sutton.
WEDNESDAY,	JUNE 30	Horticultural Shows at Croydon, Reading, and Ealing.
FRIDAY,	JULY 2	National Rose Show, at the Crystal Palace.
FRIDAY,	JULY 2	SALE. Imported and Established Orchids; also, Palm seeds, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—62.6°.

ACTUAL TEMPERATURES:—

LONDON.—June 23: Max., 53°; Min., 62°.

PROVINCES.—June 23 (6 P.M.): Max., 51°; at York; Min., 39°, Sumbrough Head.

Floral Decorations.—The joyous occasion we are in London passing through has been pronounced on Jubilee Day. In the absence of a distinctive outbreak of the decorative malady, but thanks to the relatively restricted route taken by the procession, we have not to record its spread into the other parts of the town. That the employment of real flowers and foliage in street decoration would have benefited our friends, the florists and the growers, is beyond doubt; on the other hand, an equally estimable class, the artificial flower makers, would have been the losers—and seeing that Jubilees, and other occasions for public high jinks, come but rarely, we cannot but rejoice that the latter have had the supplying of some miles of wreaths, festoons, and the manifold devices to be seen on private and public buildings. As compared with occasions so recent as the Thanksgiving Service in 1872, and the Fifty Years' Jubilee of 1887, the decorations of Tuesday show several novelties. It will suffice to mention the use made of celluloid globes, in which to place electric glow-lamps; the very general use of electric-lights enclosed in glass globes, to define the outlines of buildings, of which admirable examples were to be noted at the Bank of England, the great hotels in Northumberland Avenue, some buildings in the neighbourhood of the Mansion House, and in the electric lighting of the Strand, which last was of an exceedingly effective character. A necessarily hurried visit to the decorated streets by daylight reveals some features the nature of which, under artificial light, was not clearly made out. We refer in this connection to decorative effects that were the most striking perhaps of all, and which were mainly obtained by the employment of plants, natural foliage and cut flowers. We think, and those of our readers who may have remarked it will

agree with us, that the sumptuous *Daily Telegraph* offices in Fleet Street were very beautifully festooned, draped, and enlivened with flowers and foliage. The festoons and drapery consisted of Thuja foliage, and the flowers mostly those of Cattleyas, which are notorious for maintaining their freshness for days after removal from the plants. The flat surface of the building was relieved by bunches of the foliage of Palms and Cycads, and bas-reliefs of crowns, outlined with small white flowers, of mottoes, and words of welcome.

The *Daily News* offices, opposite, had its windows turned into veritable bowers of rusticity by employing evergreens to line and arch them over, and out of which the glow of coloured lamps partially lit up the gloom. The next house to this one in Bouverie Street had a simple yet effective decoration of bunches of bleached Palm foliage, and Pampas-grass plumes, not used extravagantly, but, all the same, showing up well against the glistening new coat of stone-coloured paint.

The office of the *Illustrated London News* was covered, as regarded its bare wall spaces, with a neatly-arranged draping of common Box, and the *façade* was furnished with boxes containing alternately plants of Rhodantha Manglesi and white Marguerites, a large coloured view of Windsor Castle, as seen from the town, topping the building. We heard that this view was supplied with running water to represent the river Thames, but we cannot vouch for the correctness of this statement.

The Griffin at the Law Courts was surrounded, as regarded the base of its pedestal, with Ferns, evergreen shrubs, and flowering plants in variety, which served to hide and preserve from injury what is beautiful, that is, the carvings on the pediment, and some festoons at each of the four corners completed the scheme of decoration.

The upper portion of the house adjoining Somerset House, that of Messrs. THRESHER & GLENNY, was very prettily decorated with some neat kind of greenery attached to light wooden trellis-work, fastened to the walls, amongst which Roses and other flowers were arranged together with glow-lights, and on the *façade* were boxes filled with flowers in variety. The effect was good so long as the flowers preserved their freshness, but the tropical heat of Wednesday destroyed them.

What our fellow citizens in the Borough or at the West End accomplished by the use of Flora's productions we are unable to say, excepting that St. James' Street was beautifully decorated with Venetian masts, floral festoons, and garlands, &c.; but we think that the City remains an unchallenged first in the matter of decorations, as it undoubtedly is in all that relates to public entertainments and festivities.

A Royal Orchid Bouquet.

We had on Monday last the rare pleasure of witnessing the making of the bouquet ordered by Her Majesty the QUEEN, for the decoration of the dining-room at Buckingham Palace on Jubilee Day. The delicate and tasteful work of putting it together took place at Messrs. WILLS & SEGAR'S conservatory at South Kensington, the flowers being furnished by that celebrated firm of Orchid importers and cultivators, Messrs. F. SANDER & Co., of St. Albans. The frame-work of the bouquet consisted of a basket made of wicker-work, heavily gilt, standing on a polished mahogany base; in shape trifoliate, beautifully fluted and worked. From the three corners spring the handle, its three branches forming a dome, surmounting

the top of which is a Royal crown, the letters "V. R. I.," 12 inches in length, being arranged beneath the crown, which consists of several hundreds of flowers of *Odontoglossum citrosimum*, the letters being composed entirely of the orange-coloured *Epidendrum vitellinum*, Millais' favourite Orchid. It is impossible to attempt the description in detail of the many thousands of Orchids used in this the most superb bouquet ever seen, endless spikes of all that is best and rarest from HER MAJESTY'S dominions being used, together with almost priceless blossoms of the hybridist's art raised in this country since our QUEEN'S accession, many of them unique and of great value, among the choicest varieties being Cattleya Empress of India, C. Our Queen, and C. Victoria Regina, which received awards at the meeting of the Royal Horticultural Society on the 15th inst. The Princess of Wales *Odontoglossum* were prominent in magnificent pure white spikes, as also were Lord Dalhousie's *Dendrobium*, with its nankeen-yellow and maroon blossoms. The sprays of the *Disa* from Table Mountain; *Stenoglottis fimbriata longiflora*, also from South Africa; the *Moth-flowered Dendrobium*, from Australasia and British New Guinea; *Vandas*, from the British East Indies; Cattleyas and richly-coloured *Oncidium*s, from British Guiana; and the lovely scarlet *Epidendrum vitellinum* and *Lælia xanthina*.

Among the more rare species and varieties employed, mention may be made of the white *Sobralia leucantha*, the beautiful hybrid *Phaius Owenianus*, *Vanda teres* Hooker; the white-pouced variety of *Cypripedium Godsefroye leucocidium* var. *Godsefroyana*, an importation possessed only by Mr. R. H. Measures, of Orchid fame; the Luxemburg variety of *C. caudatum*, *Dendrobium Phalænopsis*, the spikes of which are admirably adapted for bouquet-making; *Oncidium Batemanianum*, with its beautiful yellow expansive lip and brown crest; *Calanthe Lauchiana*, a cross between *C. Sanderiana*, and *C. veratrifolia*, the flowers coloured lilac and white; Cattleya Harrisoni, *Masdevallias*, chiefly varieties of *Harryana*, and a few *M. Chimera*.

The handles of this magnificent basket of Orchids were fitted with flutes or sockets, and the flowers were placed in them, with the spikes entire, and, in very many instances, the whole bulb and leaf also. The interior of the basket, which had to be specially designed and constructed for the occasion, is one central dome, forming a solid foundation, supporting the whole mass of blossoms, which, perfectly finished and arranged, had a height of 8 feet, with a diameter of 6 feet. The number of flowers in the bouquet in 1887 was 50,000, but this high trophy contains a larger number, while the quality is better, and rarity greater; and by command it was delivered at Buckingham Palace on Monday afternoon. The bouquet, on the termination of the Court Dinner, was carried into the Queen's Boudoir, which it served to adorn for several days.

GHEENT HORTICULTURAL SOCIETY.—The last meeting of this Society, which took place on Sunday, June 13, in the Casino. Certificates of Merit were given to the following plants:—*Anthurium Rothschildianum* var. and *A. Andreanum* var., shown by M. Louis de Smet; *Stenorchynchus speciosus* var. *maculatus*, shown by M. A. Rigouts; *Odontoglossum crispum splendens*, shown by M. L. De Smet-Duivier; *O. mulo odoratum*, *Lælia grandis tenebrosa* var., and Cattleya *Mossie alba*, shown by M. J. Hye; Cattleya *Mossie* var., shown by M. le Comte J. de Hemptinne.

FIG. 102.—*FIGOEA BIRDA*, A COMMERCIAL PLANT, GROWING IN AN OPEN-AIR POND ARTIFICIALLY HEATED, IN THE GARDENS OF MR. C. S. NASH, GILFON, NEW JERSEY.

ROYAL HORTICULTURAL SOCIETY.—The next fruit and floral meeting of the Royal Horticultural Society will be held on Tuesday, June 29, in the Drill Hall, James Street, Westminster, from 1 to 5 P.M. On this occasion special prizes will be offered for Roses; and at 8 o'clock a lecture will be given by Mr. JOSEPH CHEAL, F.R.H.S., on "Storing and Preserving Fruit."

JUBILEE HONOURS.—Among the Jubilee honours we note, with great pleasure, that Sir JOSEPH HOOKER, who, during his tenure of office as Director of the Royal Gardens, Kew, did so much to develop the resources of the Colonies and of India, has been promoted to the dignity of Grand Commander of the Star of India, G.C.S.I. Amongst other eminent men of science who have been honoured on this occasion are Drs. FRANKLAND, HUGGINS, and LOCKYER, who are severally raised to the dignity of K.C.B., while Mr. CROOKES becomes Sir WILLIAM CROOKES.

THE DISASTER AT YORK.—It is no time to dwell upon disaster in the midst of Jubilee celebrations of unrivalled magnitude and success, but we cannot avoid expressing our sympathy with the executive and the exhibitors at the recent York Gala. In our uncertain climate we are never free from such risks, but it is to be hoped that good may come out of evil, and that the catastrophe at York will result in the discovery of means for the prevention of a similar wreck under like circumstances.

THE LAST NUMBER OF THE "ORCHID ALBUM."—Orchid-growers will regret to hear that with the last part of the eleventh volume the *Orchid Album* is brought to a close. The discontinuance of so instructive and trustworthy a publication will be felt as a severe loss by many of its readers and admirers, especially as among a host of horticultural journals there is none which can exactly fill its place. The *Orchid Album* was commenced by Mr. D. S. WILLIAMS and Mr. ROBERT WARNER, in 1852, and they have had various collaborators and helpers in their work, some of whom (Messrs. THOMAS MOORE, B. S. WILLIAMS, ROBERT WARNER, and W. H. GOWER) have not lived to see the termination.

KEWITES CRICKET.—A match, played on Saturday last, on Kew Green, 'twixt present and past Kewites, resulted in a win for the present men, who scored 123 runs, against their predecessors' 52 runs. The "past" were represented by ten men only.

"CLAY'S SUCCESSFUL GARDENING."—This is a little work the main object of which is to make known the virtues of Clay's manures, which really needed no such publication. We should have imagined that a publication of this character would have injured rather than have promoted the sale of the compounds, as it does not confer lustre on the contributors.

BEDDING PINKS.—Mr. GEORGE SMITH of Penrose Street, Walworth, sent us, some days since, a collection of single Pinks of a highly decorative character, and well suited for cutting. If disbudded the flowers would be very large, but the profusion of bloom is preferable. Mr. SMITH also enclosed a mule Pink raised from *Dianthus multiflorus* crossed with a Pink. The flowers are those of the *Dianthus*, the habit that of the Pink. For flowering in beds or borders these Pinks of Mr. SMITH's are very desirable.

"INDIAN GARDENING."—A weekly gardening paper, on the model of the *Gardener's Chronicle*, is about to be issued in Calcutta, under the title above given. Gardening notes from the several Provinces and Provinces, including the Hill Stations, will be published, so that gardeners in every corner of India will find in *Indian Gardening* something to interest them.

HAWAIIAN ISLANDS.—In the *Minnesota Botanical Studies*, in addition to many articles of interest is one which has special significance at this time. It is Mr. HELLER's observations on the Ferns and Flower-

ing plants of the islands. The isolated position of the islands renders their flora particularly interesting. There are about 1,000 Ferns and flowering plants known, of which no fewer than 653 are endemic Ferns are very abundant, grasses, composites and Leguminosae, comparatively rare.

HAMBURGH EXHIBITION.—The second special Exhibition will be held from July 2 to 6 inclusive. The chief classes are (Gloxinias, Achimenes, Streptocarpus, cut flowers (especially Roses), bouquets, fruits, and vegetables.

"BOTANICAL MAGAZINE."—The June number contains coloured illustrations and descriptions of the following plants:—

Banathera Storici.—A native of the Philippines, described in our columns by Reichenbach in 1850, vol. xiv, p. 296. The flowers are much larger than those of *R. coccinea*, of far more vivid colouring, the segments broader, and the lateral sepals more undulate; t. 7537.

Strobilanthus callosus.—An Acanthaceous shrub, native of Western India. The stems are cut and used with mud in making the native huts. The oblong, lanceolate, pilose leaves have medicinal properties. The buds are very fragrant. The flowers are in clusters, with broad boat-shaped, leafy bracts, linear sepals, two-lipped corolla, with a short, thick tube, and a flatfish 5-lobed violet-coloured limb. An attractive stove shrub; t. 7538.

Vernonia diosmifolia, var. *trispala.*—A dwarf New Zealand shrub, with small linear, oblong-acute leaves, and small clusters of pale lilac flowers; t. 7539.

Begonia Baumanni.—One of the tuberous *Begonia*s, native of Bolivia, with transversely oblong male flowers, and circular female flowers, with short, pleated stigmas, involute at the margins. The colour is a rosy-pink. Kew; t. 7540.

Laelia longipes. Rehb. f.—A small-flowered Brazilian species, with narrow-spreading lilac segments, and a yellow lip, the anterior lobe of which is undulate; t. 7541.

JUBILEE ENTERTAINMENT AT CARLISLE.—Messrs. LITTLE & BALLANTYNE entertained on Monday night last their employes to the number of about 200 at the nurseries at Knowfield.

MR. LADD'S NURSERIES.—"I did not walk through every house, but simply looked in at the doors; to walk the length of every house would mean a tramp of six miles, or thereabouts. There are two large blocks of houses (mostly connected by gutters), 101 in all, ranging in length from 300 to 700 feet each. One house of Grapes, 30 by 700 feet, makes one feel that America has not all the big things in the world. Several of the largest houses are vineries, but they have not as many now as formerly, and most of the place is devoted to small Palms, Ferns, Dracaenas, Ficus, Geraniums, Pelargoniums, Fuchsias, Genistas, Cinerarias, and similar spring plants for the Covent Garden Market; and when the houses are emptied of these, Tomatoes take their place. The plants are all carried to London, a distance of 15 miles, in five large vans, leaving at night, and arriving in London in the early morning; it seems almost impossible that these immense blocks of plants could be conveyed in this manner, or find a sale upon arrival. I was told that with such plants as Fuchsias, Pelargoniums, and Cinerarias, when they are in bloom and saleable, they are rushed into the market regardless of the price until 10d. per dozen is reached, then they stop—not a very fancy price for blooming plants in 5-inch and 6-inch pots. This place is deserving of notice simply on account of its size; it is only one of four large places owned and operated by Mr. LADD, which undoubtedly makes him the largest individual owner of greenhouse structures in the world. The four places combined will probably cover from one and a half to two million square feet of surface—a larger area than would be covered by any ten concerns combined in America. A large place is not necessarily a successful one, however, or one to be held up as a model. I was told that after the houses were once built they are

never repainted, very little repairs are ever made, and as soon as a house gets in very bad shape it is considered cheaper to pull it down and put up a new one than to repair the old. It may be worth a trifle to be known as the largest florist in the world, and to have built up such a vast concern in a single lifetime; but the sensible man will put up no more glass than he is prepared to properly care for. *Robt. Simpson, in the "American Florist."*

"BOLETIM DA SOCIEDADE BROTERIANA."—The thirteenth volume, that for 1896, has lately reached us. It contains important communications on the botany of Portugal, from the pen of Prof. HENRIQUES and other botanists.

THE FLOWER TRADE.—The cut-flower trade has been very brisk this week, the chief demand being for Roses, and for flowers red, white and blue. The decorators have also been very busy.

PINK CUPID.—The first Cupid was short of stature, and white, but it will not be a matter of surprise that some of his successors should be pink. Such is the case with a Sweet Pea before us, of which seeds were obligingly sent to us some time since by Messrs. BURKE & Co., of Philadelphia. The plant (ought we not to say haun?) is rather taller than in the original Cupid, and the whole surface is, we take it, somewhat more hairy; the hairs being rigid, with a bulbous base, intended, we presume, to keep off marauders. The leaflets are oblong-retuse, rounded at the base, and the petiole deeply winged. The stipules are linear-lanceolate, somewhat falcate, nearly as long as the petiole. We give these details because they suffice to show the distinct habit of the plant; the width of the standard is about 1½ inch (or 3 cent.), its length being about the same. Its form is roundish, notched at the apex, and its colour a delicate rose-pink. The wings are broad, and of a still paler hue; the keel is quite white. It is an interesting addition to our collections of Sweet Peas.

"THE BOTANICAL MAGAZINE FOR 1837."—The volume for the year 1837 was edited by Sir WILLIAM HOOKER, who had not yet taken over the charge of the Royal Gardens at Kew, but was at that time Professor of Botany and Director of the Botanic Gardens, Glasgow. It was dedicated to "JAMES BATEMAN, Esq., of Knyresley Hall, Cheshire, author of the magnificent *Orchidaceae of Mexico and Guatemala*, a work of which it is hard to say whether the beauty of the subjects represented, the execution of the figures, or the taste and judgment displayed in the topographical department, is most to be admired; the present volume is dedicated with sentiments of high regard and esteem by his obedient friend and servant, W. J. HOOKER."

KEW GUILD.—The fifth number of the *Journal of the Kew Guild* has been issued, and amply maintains the interesting character of its predecessors. It opens with a portrait and a brief notice of Mr. J. G. BAKER, who has contributed so largely to horticultural botany. Details are given concerning the annual meeting, and various items of interest to old Kew students are added. Miss A. M. GULVIN has been appointed head gardener to J. BROOKE, Esq., Iscote, S. Wales. Miss GULVIN writes that "My men are all that I could wish, no cause for anxiety at that quarter." The notes from "Old Kewites" in various colonies and in foreign countries are particularly interesting. It is to be hoped that this feature will, if possible, be extended. As complete a list of old Kewites and of their present places of residence as possible, is added. Long may the guild flourish!

"THE ENGLISH ILLUSTRATED MAGAZINE."—The July number of this publication is entirely devoted to a retrospect of the events of the last sixty years. It includes articles upon the QUEEN and Royal Family, and others on such subjects as—"State Pageants of the Victorian Era," "The Queen's Army," "The Historian of the Queen's Reign," "The Queen's Head" (?), "Retirement of Victorian Women,"

"Drama of the Victorian Era," "Literature of the Victorian Era," &c. It is, as usually, well got up, and handsomely illustrated.

GRAFTING OF HELIANTHUS ANNUUS AND LÆTI-FLOLUS.—The *Revue Scientifique* recently contained a note upon an experiment made by M. L. DANIEL, who, in the spring of last year grafted the large annual Sunflower (*Helianthus annuus*) on *Helianthus lœtiflorus*, and *vice versa*. The former has a stem with a whitish skin, covered with hairs, which are persistent for some time; the leaves are distinctly coriiform. It is annual, and consequently forms no reserve or store-matter in its stem or in its root. It is pauciflorous. The other plant has a green stem, with feeble hairs, with numerous lenticles in the adult stage; the leaves are lanceolate; it develops perennial root-stocks, swollen at the tips, and containing a reserve of inuline. It is multiflorous. They are therefore two species of the same genus, which differ markedly in outward form and in character. The results which the experimenter obtained from grafts between these plants led to the following conclusions:—1st. The direct influence of the stock and of the graft is reciprocal in *Helianthus*. The action of the stock is predominant on the form of the foliage of the graft, and is also evident in the blooming; the action of the scion is exercised especially on the mode and duration of the growth of the stock. 2nd. There must therefore be a substitution between the formation of tubers and that of wood when the species of *Helianthus* pass into the resting stage.

MUNICIPAL GARDENS, CAPE TOWN.—As an object-lesson, the plantation of succulent *Euphorbias*, *Opuntias*, &c., in the Municipal Gardens, Cape Town, is very striking (fig. 163). The trees in the background are necessary probably for shelter, but their forms are in rather violent contrast with the quaint forms of the succulents; but gardeners, to no small degree, manage to set the "environment" at defiance, and here we have plants, which usually grow under very different conditions, associated together.

ROYAL SCOTTISH ARBORICULTURAL SOCIETY.

—A General Meeting of the Royal Scottish Arboricultural Society will be held at No. 5, St. Andrew Square, Edinburgh, on Monday, August 16, 1897, at 2 P.M. R. C. MUNRO FERGUSON, Esq., M.P., President, in the Chair. The members of the Council and the judges will meet at 1 P.M. The business, which will occupy the attention of the meeting, includes the election of new members, election of two trustees in room of Dr. CREGHEON and Mr. ROBERT HUTCHISON deceased—Lord BALVAIRD and Mr. MUNRO FERGUSON, M.P., are recommended by the Council for these vacancies; election of additional local secretaries; an address by the president, or an eminent specialist; "the best methods of converting timber," by "Economist"; "the best methods of converting timber," by "Sawdust"; "the afforestation of waste land," by "Arboreal"; "forestry and game preserving, and how they may be worked together," by "Enthusiasm"; "the forest institute of Vallombrosa," by "Thick as Autumn Leaves," &c.; "the planting and management of hedges," by "White Thorn;" excursion in 1898; library and museum; and papers by Mr. C. C. Henkel, Conservator of Forests, Umata, Cape Colony, on "The Forests of South Africa and their Future;" and by Mr. MALCOLM DUNN, Dalkeith, on "Forestry in Scotland during the Sixty Years of the Queen's Reign." The Council recommend that members of the society should use their influence with town and County Councils, and other local authorities, as well as landed proprietors generally, to induce them to plant specimens of ornamental trees, avenues, groups, and woods of all sizes, during the ensuing season, to commemorate in an appropriate manner the Queen's Diamond Jubilee Year. The twentieth annual excursion of the Society will be held on August 17, 18, 19, and 20, 1897, in the counties of Dublin, Wicklow, and Kildare, Ireland, and immediately thereafter a supplementary excursion will be made to the Lakes of Killarney with the option of returning by

Glengariff, Cork, and Mallow to Dublin. Permission to visit their estates, parks, &c., has been graciously granted by the following:—The Commissioners of Public Works in Ireland; the Director of the Department of Science and Art, Dublin; Lord Ardilaun, Viscount Powerscourt, Viscount Monck, the Earl of Meath, Earl Fitzwilliam, the Duke of Leinster, Charles R. Hamilton, Esq., of Hamwood, the Earl of Kenmare, and H. A. K. Herbert, Esq., of Muckross. Members intending taking part in the excursion must intimate their intention to the secretary not later than Saturday, July 17. Members may join the party at Greenock or Dublin, provided they mention this when sending their intimation; and they must intimate whether or not they intend to take part in the trips to Killarney and the extension via Glengariff to Cork. Each member must send to the secretary, along with his intimation a deposit of 10s. to defray the preliminary and other necessary expenses. Other particulars as to this trip can be obtained on application to the secretary, R. GALLOWAY, Esq., 5, St. Andrew Square, Edinburgh.

POLLINATION OF ORCHIDS.—The *Orchid Review* gives an account of some interesting observations which have been recently made at Kew by Mr. GRIESEN. He caught a bumblebee with three different kinds of pollinia attached to it. Between the eyes were two pairs from one *Odontoglossum*, on the middle of the thorax four pollinia of a *Cattleya*, and on the back of the thorax between the wings, those of some *Yanda*, which proves that the bee fed among various species. Another interesting example was that of a common bluebottle-fly with the pollinia of a *Cirrhopetalum* affixed to the middle of its thorax. The flower had evidently attracted the insect by its fetid odour.

JUBILEE PUBLIC GARDENS.—West country readers of the *Gardeners' Chronicle* will be interested to learn that Mr. F. W. MEYER, landscape gardener, in the employ of Messrs. ROBERT VEITCH & SON, nurserymen, of Exeter, has been successful in gaining for the firm two competitive plans for laying out public gardens in commemoration of the Jubilee, namely, for Gardens at Yeovil and Crediton. For the Yeovil Garden nine plans were sent in.

BOTANICAL EXCHANGE CLUB.—The report for 1895 has only recently reached us. It is edited by Mr. BEEBY, and consists in a series of comments upon plants of doubtful position, or which are otherwise interesting.

"FAVOURITE FLOWERS."—The last part of this useful popular production is devoted to Orchids. Novices desirous of increasing their knowledge of these plants will find much help from these parts.

"FLORA CAPENSIS."—We note with great satisfaction the publication (by Messrs. L. REEVE & Co.) of the third and concluding part of the 6th volume. The work was commenced by HARVEY and SONDER, remained in abeyance for several years, but has at length been taken up again under the editorship of the Director of the Royal Gardens, Kew. Its limitations have been so extended as to include not only the Cape Colony proper, but the whole of South Africa up to the Tropic of Capricorn. The present part is devoted to the continuation of the Liliaceae, and is entirely the work of Mr. J. G. BAKER. It is hardly possible to overstate the value of his recension. Many of the species have hitherto been collected only once, and are not represented in gardens or herbaria. Those that are in botanic gardens are often badly named, so that this authoritative descriptive enumeration will be of exceeding use. Mr. BAKER has largely availed himself of the unrivalled collection of living plants at Kew. A large number of "Cape Bulbs" are of course included in this part, valuable for their beauty, their interest, and their adaptation to the peculiar climatal conditions under which they grow. With the vast expansion of British territory, the collecting area has increased proportionately, and, no doubt, many of the species at present little known will speedily become familiarised

to botanists, while it is certain that many novelties yet remain to be discovered. The Editor in the preface sketches the history of the work, and the more or less inevitable delays that have occurred in its publication, and reads a well-earned meed of praise to Professor MacOwau, Mr. Harry Bolus, Sir Henry Barkly, Mr. J. Medley Wood, and various other collectors.

PLANT PORTRAITS.

CATAPETUM SPLENDENS VAR. *RUPELI-NOSA*.—Segments deep brownish red, with purple spots; lip yellow. *Lindleya*, t. 12, p. 17.

CATAPETUM LABIATA SUPPLEA.—A variety in which the segments and the lip are unusually slender in their deep coloration. *Lindleya*, t. 12, p. 18.

CATAPETUM MARTINI (SCHIMMER) DOWNING.

CATAPETUM MAXIMA VAR. *VEITCHIANA*, *Lindleya*, t. 12, p. 18.

CATAPETUM MOSSIE MONDI, LA GUARA, *Williams' Orchid Album*, t. 525.

CATAPETUM SCHILLESIANA, H. G. R. Hb. f., Brasil, *Williams' Orchid Album*, t. 525.

CATAPETUM "THE CAZAR".—Supposed to be a natural hybrid between *C. lobata* and *C. granulosa* (see *Gard. Chron.*, Nov. 14, 1896), *Lindleya*, t. 12, p. 18.

CATAPETUM TRIANGULARE VAR. *EXORNATA*.—Lip with a rich yellow blotch in the centre, and a purple stain in front. *Lindleya*, t. 12, p. 18.

CHRYSOPELUS VILLOSA, *Mechan's Monthly*, June.

CYMBIDIUM LOWIANUM VARIE, BURNAL, *Williams' Orchid Album*, t. 527.

CYPRIPEDIUM VICTORIE MARIE, *Gard. Chron.*, 1893, i., p. 613; *Lindleya*, t. 12, p. 18.

EAUSTHEMUM NEVADENSE, *Garden*, May 15.

LELIA LINDLEYANA, R. Hb. f., S. Brasil, *Williams' Orchid Album*, t. 526.

LEPTOSPERMUM SCOPARIUM GRANDIFLOLUM, *Garden*, May 29.

MASDEVALLIA HENRIETTEAE, KRAZDIN (figura × Shuttleworth), *Gard. Chron.*, XIII, 1895, p. 740; *Lindleya*, t. 12, p. 18.

ODONTIUM PHALENOPSIS VAR. EXCELSUM, *Lindleya*, t. 12, p. 18.

ONCIDIUM SPLENDENS, *Garden*, June 5.

PLEM. DRAP D'OR D'ESPEREN, *Bulletin d'Arboriculture*, &c., May 1.

TRICHOPILOA VEITCHI, *Garden*, May 22.

PLANTS OF THE VICTORIAN ERA. FLOWERS.

SINCE the Hon. and Rev. William Herbert, in 1831, published his preliminary treatise on the *Amaryllids*, in which he named "the shelly and foliaceous seeded occidental *Amaryllids*, *Hippeastrum* or *Knights' Star Lily*," wonderful progress has been made in the direction of improvement. In 1837 the leading species were *A. calica* and *A. vittata*, and from these a very few garden varieties had been obtained. In the quarter of a century which followed, not a few seedlings were raised; the finest were found at the great International Exhibition held at South Kensington in 1866, when but few species were shown, but many more of home production. From that time onward the advance has been most marked, Messrs. Veitch & Sons greatly distinguishing themselves as raisers; and the names of Williams, Paul, Douglas, Perkins, Ker, Kelway, and others, are associated with the improvement of the *Hippeastrum* in more recent times. Awards to new varieties are now seldom made, owing to the high level of quality found in the latter-day seedlings.

AURICULA.

Not less striking has been the onward march towards perfection of the *Auricula*. At the time of the accession of the Queen, the leading green edges were Colonel Taylor, Booth's Freedom, Prince of Wales, and Lovely Ann; and of these, the two former are still to be found in collections. Grey edges: Conqueror of Europe, Ne plus Ultra, Complete, and Privateer. White edges: Taylor's Glory, Regulator, Regular, and Catharina. Selfs: Lord Lee, Metropolitan, Othello, and True Blue. Alpine varieties were few, and chief among them *Conspicua*, a flower still to be found in collections in the north, where the work of improvement has not kept pace with that in the south. Lancashire

Hero, still one of the finest grey edges, appeared in 1846; and Heap's Smiling Beauty, white edges, still cultivated, a little later. Dickson, of Brixton, was successful as a raiser; later notable producers were Lightbody, Headly, Simonite, Woodhead, Mellor, Douglas, Horner, Barlow, &c. The alpine section has been marvellously improved during the past forty years, especially in the hands of Mr. Charles Turner and his successors, and Messrs. Douglas,

was the beginning of the production of the fine varieties occasionally met with in the present day. Both as a decorative and exhibition plant the Achimenes has lost ground, a retrogression, perhaps, caused to some extent by the greater favour shown to the Gloxinia and Streptocarpus. Large pans and pots of the leading varieties were at one time a feature at our leading exhibitions, and they still put in appearance at some provincial flower-shows.

attractive. The white form of *A. chrysantha* is much esteemed, and one of the latest introductions—Stuarti—is a charming dwarf blue early-flowering type. *A. glandulosa* and its varieties do best in the cool, moist districts of the north.

AZALEAS.

The Chinese Azalea, like the Camellia, has decidedly declined in popular estimation, the latter in a more marked manner than the

FIG. 163.—MUNICIPAL GARDENS, CAFE TOWN. (SEE P. 422.)

Phillips, Walker, and others have raised fine varieties also, some of which will be grown and exhibited for years to come. The centre of cultivation of the *Auricula* for exhibition is now more in the south than in the north as formerly.

ACHIMENES.

The *Achimenes* has in late years ceased to be grown as much as formerly. In 1857, the scarlet *A. coccinea* appears to have been the only species in cultivation; but during the forties there were several introductions, notably *A. patens*, *A. longiflora*, in 1841; and in all probability the crossing of this and *A. coccinea*

Some two dozen or so varieties, to which additions are occasionally made, afford ample choice for those who are induced to cultivate this generaceous plant.

AQUILEGIA.

The *Aquilegia* is deservedly popular, and is increasing in popularity. Sixty years ago *A. alpina*, *formosa* (californica), and *glandulosa* were almost the only imported species cultivated; the double and single forms of *A. vulgaris* were largely grown until *cerulea* appeared in 1864, and *chrysantha* in 1873. This led to crosses being effected, and now the hybrids of *cerulea* and *formosa* are highly varied and

former. *A. indica* and *A. sinensis*, *A. nudiflora* and *A. pontica*, were in cultivation sixty years ago, and the three latter had undergone considerable improvement; that of the Chinese *Azalea* came later. The latter is still grown largely for decorative and market purposes, the double-flowering varieties are more popular than the single flowered because more persistent. New varieties appear but infrequently, certain old ones are yet standard favourites. As an exhibition plant, the *Azalea* has particularly declined, the huge examples of thirty years ago have disappeared. One reason for large specimens being so rarely seen is owing to the

fact that there are now but few exhibitions when the plants are at their best. *A. amoena* and its varieties are valued for their free-blooming quality; the double forms of the hardy American Azaleas are now many and very fine.

BEGONIAS.

Probably no popular flower has come to the fore with greater élan than the Tuberos-rooted Begonia. At the time of the Queen's accession, and during the first twenty-five years of her reign, it was unknown. It was the discovery in Polivia, by Mr. Pearce, of *Begonia boliviensis* in 1867 which gave the great impulse to the cultivation of the tuberos Begonia. A cross made between *B. Veitchii* and *B. boliviensis* resulted in *B. Sedenii*, which was sent out in 1870; then followed *intermedia*, *Chelsoni*, *Stella*, *Vesuvius*, and succeeding varieties. It was at once seen there was a great future for the flower. It was taken in hand by Messrs. Laing, Cannell, Rev. Lascelles of Bath, and many others, and by MM. Lemoine and Crousse in France, and in the present day it has developed single and double forms of such amazing beauty and perfection, as to more than realise the most sanguine anticipations of its first cultivators. The blossoms of the most advanced of the single varieties are nearly or quite circular; those of the double types are large, full, and symmetrical. The tuberos-rooted Begonias have proved to be the most useful and effective of bedding plants. Other species such as *B. Froebeli* (1872), have been much employed in securing diversity, and most useful crosses have resulted.

The introduction of *B. socotrina* from the island of Socotra, in 1880, afforded another valuable species for cross-fertilisation, and by using it as a seed-parent, crossed with some of the summer-flowering tuberos varieties, a new race of winter-flowering types has been obtained. In fact, the development of the Begonia appears to be almost illimitable, and every year witnesses the addition of something of value. Varieties of the subpetala type, with handsome foliage and attractive flowers, all of continental origin, are highly appreciated for flowering in winter and spring; and of the perpetual-blooming and evergreen kinds, there are now many of great value, including the charming dwarf bedding-types originated by Messrs. Sutton & Sons.

CALCEOLARIAS.

The Calceolarias of sixty years ago were limited in number, small in size, and tall in growth. Four species were introduced from Chili or Peru in 1822, and our forefathers no doubt seeded from them. In 1837 but little improvement had been made, but Plant of Cheadle had, in 1842, advanced with seedlings, and originated some pretty striped varieties in 1848. Major, Constantine, Kinghorn, and others, carried on the work of improvement, and by making use of the sub-shrubby species improved the habit of the plants. Gaines and Dobson, with others, carried on the work still further. Cole, of St. Albans, originated a distinctly shrubby section; and by making use of some of these, James of Isleworth further reduced the habit of growth of the herbaceous type, and imparted compactness and vigour to it. The introduction of a very dwarf-growing type from the Continent became the progenitor of the low compact habit seen in the strains of the present day. The flowers have increased enormously in size, the trusses of bloom are considerably larger; the points of quality which ruled fifty years ago are no longer regarded.

CINERARIA.

Much the same procedure has happened in the case of the Cineraria. In 1837 the varieties in cultivation were much the same as the seedlings from *cruenta* Mr. Lynch and others have been exhibiting during the last two years. It was not until ten years after, when Messrs. E. G. Henderson & Son introduced *Beauty of St. John's Wood* and *Middle Cerito*, that the work of improvement set in, in earnest; the Cineraria, as a decorative and exhibition plant, was in its greatest glory from 1854 to 1864. As in the case of the Calceolaria, the introduction of a dwarf continental strain has brought a corresponding change in the habit of growth, while the flowers have attained to enormous proportions. As an early-flowering greenhouse plant, it is of great value; but it is nearly time there was something like a harking-back to old points of quality. There are indications that this work is in course of being carried through again, and it is needed.

CAMELLIA.

In 1857 there were probably sixty or more varieties of *Camellia japonica* in cultivation. It was then and for years afterwards highly popular, as Thackeray has taught us—the button-hole flower *par excellence*. Chandler, Loddiges, and Masters, among others, were originating new varieties when the Queen was a child. Up to within the last twenty years or so, new varieties frequently appeared; but with the introduction of the American *C. M. Hovey*, the high-water level of improvement appears to have been reached. *C. imbricata* has been in cultivation almost from the birth of the Queen, and the old double white nearly as long. But the decline of the Camellia is noticeable, and cut blooms find but little recognition in our markets.

(To be continued.)

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

JUNE 15.—Present: Dr. M. T. Masters, in the chair; Dr. Muller, Dr. W. Wilks, Dr. Bonavia, and Rev. J. Henslow, Hon. Sec.

New Method of Grafting.—Dr. Masters called attention to the fact that the method described at the last meeting had been adopted before by A. Knight; but on turning to that author's paper (*Trans. Hort. Soc.*, vol. i, p. 239) it is not quite clear whether it is quite the same. According to Knight's figures, the extra "tongue" is not inserted as a duplicate scion, but nailed to the outside of the bark; but in the text it would read as if both tongues grew and covered the stock.

Synanthus Euphratica.—Specimens were sent from Chiswick, in which the terminal flowers had coalesced, producing a large campanulate structure. This is a familiar monstrosity; but it appears that M. Vilmorin has succeeded in fixing it; over 95 per cent. of seedlings, raised from the normal flowers of the spike, are said to come true, and bear them campanulate blossoms.

Fasciated Buttercup.—A rather curious example was sent by Miss Coppen of Highfield, Hartley, Plymouth, found at Denham Bridge, Devon. Two fasciated stems were so slightly coherent as to readily separate while the two symmetrical blossoms, however, remained firmly coherent.

Deflate Lily of the Valley.—Henslow showed a flower in this unusual condition, in that a scape bore a single terminal flower, in which the whorls were in fours, excepting the pistil.

Romney with fungus.—Rev. W. Dod sent specimens of *R. Coulteri* badly attacked by some fungus. It was forwarded to Kew for investigation.

Crates, Disease.—Samples of fruit, together with leaves, were received from Mr. James Cannon, of the Gardens, Aucterader House, attacked by *Gloeosporium*. The leaves appear to be scalded, so that the opinion of the committee was that this mischief should have been carefully avoided. Bordeaux spray at a very early period of the attack might have proved efficacious in checking it.

Campanula Balkaniana &c.—Dr. Masters exhibited drawings of a remarkable phenomena in this variety. The plant has variegated leaves, and is a hybrid between *C. fragilis* and *C. isophylla*. The sepals are fulvous, with petals, while

the ovary is entirely superior, and not inferior, as in all the *Campanulata*. A full description will be given later on.

Abnormal Fungi in a Mushroom-bed.—With reference to the specimens shown at the last meeting, Mr. A. Sutton undertook to transmit them to two eminent Mushroom growers, who have kindly sent the following reports:—(1) "Replying to your letter of the 13th with a sample of fungus, which is unknown. Without seeing the bed or knowing more particulars of the materials used for the same, I could hardly say for certain whether it is caused from the manure not being properly sweetened or from the mould used for casing, most probably from the latter, as I have found the same occurrence in the case of fungus and mildew, the spores being introduced through the mould; especially if this is used fresh from a pasture field, more often than this contains some kind of fungus. The only plan to avoid this is to use mould, if possible, from an arable field, or, without the turf, which has been stacked a year or more, and when using mix a small quantity of salt or slacked lime."

(2) "Replying to your inquiry of the 13th inst., I beg to inform you that the fungus sent is not frequently met with, but I have seen some before. The reason one so seldom meets with it on Mushroom-beds is because the loam used in casing the beds is usually procured from a ground, and not from the vicinity of or from under trees. I have no doubt in the least but that the fungus sent you is from the soil used, although soil used from the same heap did not previously develop it, as perhaps the previous lots of soil did not contain the spores of that species, or that the soil was not so plentifully. As several beds had been cased from the same heap, I take it for granted that the soil remained undisturbed for a length of time, and possibly under a tree or trees, which would account for its appearance in the last bed. I should say the reason it did not appear in the other cases was, because the manure for the beds was not properly prepared; that it was made up too quickly, and consequently burnt the mycelium in the sets; or that it was not sufficiently fermented, and so rotted the mycelium. If your correspondent makes up another bed, and obtains the soil by casing from a place where it is known to exist, the spore is not to blame, no matter where he had it from, as I never yet saw any false fungi where the compost has been properly prepared and good loam used. Could you procure a cake of the spore for my inspection? If so, I will make a careful examination of it, and use it with some that I am shortly spawning a bed with. I would then report further on the subject."

Rhododendron with Fungus.—Mr. W. Wilks brought a specimen of the fungus *Xylosterium rhododendri*. It is described in Dr. W. G. Smith's edition of *Tubercle Diseases of Plants*, p. 477.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

JUNE 17.—There were several very choice Orchids on exhibit in the Coal Exchange, selection rather than collection being the general order.

Among other plants, Capt. SCROFIELD (Mr. Schill, gr.) submitted a fine piece of *Cypripedium Chapmanii magnificum* (F. C. C.); this is a hybrid between *bellatulum* and *Curtisii*, extra in form, densely spotted with clear ruby on a pale fuschin ground with a prominent pouch, taking more after *Curtisii* in the shape of the petals and sepals, and a move in the right direction in the way of select crossing. The same grower had also *C. Chapmanii* (A. M. C.) = *Curtisii* x *bellatulum*. This is much inferior to the one above described, and it shows how the reverse cross may effect a change in the progeny. It is similar in ground colour and in spotting, but wants the size and substance of its fellow seedling.

WILLIAM THOMPSON, Esq., Walton Grange (gr. Mr. W. Stevens), had a finely grown plant of *Cattleya Mossie Wagneri* (First-class Certificate), with two flowers. There was no flushing about the flower, the segments and labellum blade being pure white, with two large orange-coloured blotches planted on the throat and running up to the base of column, and forming lines towards the base. The same grower showed *Odontoglossum Cordinei* (Award of Merit); this is the cleanest and brightest form of *O. Cordinei*, having prominent chestnut spots of large size on a whitish ground colour. The spike was twelve flowered.

F. SANDER & Co., St. Albans, submitted *Cattleya Mossie rubens* (Award of Merit). The flower was not large, but it was very brilliant red with a shade of violet pervading it. The lip was deep shaded violet in hue to the extremity, with bright orange blotches at the mouth of the orifice. If this came up again a little better developed, it has a chance of getting the higher award. The firm also put forward *C. M. Empress of India* (Award of Merit), a full bold flower with broad segments standing well forward, and had a showy crimson lip, which is broadly edged with pink, the orange blotches prominent, and contrasting well with the snowy white. This firm also had *Grammatophyllum Mesastriaeanum* (Award of Merit). This is a very prominent example of the species, having a flower raceme 2 feet long, carrying about 30 flowers, that reminds one of *Ansellia africana*, but they are larger. The pale brownish green, the yellowish ground of this flower are very attractive, still it is not a lined-looking plant. The other plant from this firm which received honours was *Phaius Owenianus* (Award of Merit); this is a splendid move in the right direction, its bright-coloured flowers being uncommonly attractive.

A. W. WATSON, Esq., The House, Haslemere (gr. Mr. T. Loftus), had a fine dark form of *Laelia tuberosa*, called

nigrescens First-class Certificate); the segments of this variety are concoloured a bright chocolate hue standing well out, the petals twice the width of the sepals; lip, blackish-crimson with maroon lines radiating to the base; the lower half of the limb maroon and purple combed with heavy lines running from orifice and shading out to the extremity. The same grower had also cut flowers of *Loelia purpurata grandis* (Award of Merit); this was a splendid flower with white segments and a lip of unusual brilliancy and fine form. Had it been shown as a plant it would have received the highest award. SAMUEL GRATEX, Esq., West View (gr., Mr. McLeod), had *Loelia-Cattleya Queen-Empress* (First-class Certificate); this plant was still fresh and

NATIONAL ROSE, PORTSMOUTH.

JUNE 18.—This was held in the Victoria Park, Portsmouth, in connection with the Isle of Wight Rose Society. The season being more than usually backward, it was unfortunate that, on account of Jubilee festivities, an earlier date than originally fixed was found necessary. This fact, and the severe frosts of May, together with stormy weather throughout the country, was the cause of a somewhat poor show for the National Rose Society. Still, there were some grand flowers, those from Colechester and Oxford being especially clean and bright. We do not think the best use was made of

Esq., and the Rev. Foster-Melliar's grand Teas, a great blank is sure to be felt.

There were several incidents of the day well worth noting, Mr. F. CANT was disqualified in the premier class for nurserymen for infringement of rule 7, he staging a beautiful back row flower of a sport from S.-Marie Rodocanachi, unnamed, and without giving name of raiser. It is a pity we cannot have the very earliest opportunity of seeing such a good new Rose without its being definitely named and shown under such, but as this rule was made at the last meeting, it was thought wiser to enforce it upon the first infringement.

FIG. 164.—BALMORAL CASTLE, THE QUEEN'S HIGHLAND RESIDENCE.

beautiful; it will be found described at length, as exhibited by F. Sander & Co., p. 300, col. 2, to which we have nothing to add.

H. GREENWOOD, Esq., of Highfield (gr., Mr. Spurr), exhibited a well-crown plant of *Cypripedium besicatum* (Award of Merit), with a dozen or more rather small but bright and pretty flowers. It is a wonder more has not been made of this species for crossing.

ARTHUR B. WATKINS, Esq., showed a form of *Cypripedium* in the way of *floridanum*; and a well-flowered plant of *Cattleya Mossii*, but the flowers were too small for the plant to receive a Cultural Award.

MESSRS. JONES & CO. had a miscellaneous assortment of showy flowered orchids, for which he was awarded a Vote of Thanks.

what flowers were available. For example: it would obviously have been better to allow more space to the beautiful garden Roses, instead of crowding these, and leaving so much blank space between other classes. While aware of the difficulties caused by expected exhibitors failing to appear at the last moment, we think a little more space might have been accorded what was decidedly the feature of the show, viz., garden Roses. Nor was there any shading to the front of the benches, boxes and the many elevators of lumber being fully exposed.

MEERS, HARRIS & SON, from Bidele and Hildon, also F. R. HINDSALL, Esq., from the latter town, were much missed, and when we are also minus Mr. O. G. OPEN, H. MACHIN,

Another very hard case of disqualification occurred. In a class for twenty-four blooms, and also in that for twelve, Mrs. CHERRY MUMFORD, Ryle, staged two blooms of Charles Lefebvre, one of which was named Fisher Holmes. It was quite certain from the lady's explanation that she had received the plants under the names given. The stands were well shined, and from this unfortunate error only, both the Challenge Cup and a money prize, and also the Queen's Gold Medal, were forfeited.

MR. A. TAYLOR, Featherbed, in a class for twelve Roses, soundly defeated by Captain RICHARDS, and also the Silver Medal of the National Rose Society, for the best box or Noctive, and the best H. Perpetual or H. Tea in the amateur divisions; it was a tight box for the season.

NURSERYMEN ONLY.

Forty-eight single trusses distinct.—Mr. B. R. CANT, Colchester, was well ahead, his blooms clean, and by no means small.

For twenty-four distinct groups, Messrs. CURTIS, SANFORD & Co., Torquay, were 1st with very clean flowers, their best being Margaret Dickson, Louis van Houtte, Ulrich Brunner, Duke of Connaught, Marie Baumann, Marie Badt, Duke of Edinburgh, and Horace Veret. Messrs. BURBULL & Co., Cambridge, were 2nd; and Mr. G. PRINCE, Oxford, 3rd. The Kride, C. de Nadaille, M. Niel, and Bridesmaid were very good in the last-named stand.

For twelve trusses of any Rose except Teas or Noisettes, Messrs. PRION & SONS, Colchester, were well in front, with some grand examples of Lady Mary Fitzwilliam, among which was the Medal Rose, and Mr. G. PRINCE, Oxford, 3rd. The Kride, C. de Nadaille, M. Niel, and Bridesmaid were very good in the last-named stand.

For twelve trusses of any Rose except Teas or Noisettes, Messrs. PRION & SONS, Colchester, were well in front, with some grand examples of Lady Mary Fitzwilliam, among which was the Medal Rose, and Mr. G. PRINCE, Oxford, 3rd. The Kride, C. de Nadaille, M. Niel, and Bridesmaid were very good in the last-named stand.

ANATERS.

There was an important extra class for twelve varieties, in which Captain J. RAMSAY, the local secretary, presented a 10-guinea Silver Cup, which was easily secured by Mr. A. TAYLOR, Leatherhead.

For nine singles, not less than six varieties, open only to amateurs within ten miles of Tottenham, Mr. H. G. E. CROFT MURRAY, Ryde, was successful. This secured the National Rose Society's silver medal; but the same exhibitor was very unlucky in not securing the challenge cup and also the Queen's Gold Medal in the local classes, the presence of duplicates disqualifying both stands.

Teas and Noisette Section.—The Prince Memorial Cup, for eighteen distinct single trusses, was won by A. HILL, GAY, Esq., Bath, with C. Marnet, Cleopatra, Rubens, Ernest Metz, Anna Olivier, M. Niel, The Bride, Souvenir d'un Ami, C. de Panisse, Meia, Souvenir d'Elise Varion, Madame Bravy, Princess of Wales, Innocente, Pirola, Marie V. Houtte, E. Gifford, C. Kuster, and Cornelia Koch. Mr. F. CAMPION, Reigate, was the only other competitor.

GARDEN ROSES.

These were undoubtedly the feature of the show, clean, bright, and in good form. Owing to the lack of entries, and little prospect of a representative show as so early a date in a late season, the committee introduced three extra classes for these popular and early Roses. We were sorry to see such little competition; but probably this was owing to the short notice given for the exhibition.

In the chief classes for nurserymen, that for thirty-six bunches of distinct varieties found Messrs. COOLING & SONS, Bath, 1st, with a magnificent stand, consisting of B. Morneu, macrantha, Fellenburg, Polyantha, Isabella Sprunt, Bardon Job, Persian Yellow, Commandant Beaurepaire, Madame Falou, Marquis of Salisbury, Madame P. Ducher, Camosa, William Broughton, G. Bazis, Chino Jacquier, Rosa pomifera, Papa Gontier, Anne of Gerstein, Blanche de Coubert, Parly (new). Gloire des Polyanthes, Rigosa rubra, W. A. Richardson, Lucida plena, Demott Becard, Rosa Mundi, Tuscan, Dr. Grill, White Cabbage, Hombre, York and Lancaster, and Crested Chidge. Messrs. G. PAUL & SONS, Cheshunt, 2nd; and Mr. C. T. TURSEL, Slough, followed.

In the extra class for eighteen bunches, Messrs. CURTIS & Co., Colchester, just succeeded in beating Mr. J. MATTHEW of Oxford; the last-named was very unfortunate in having a neighbour's lion crashed upon his stand a few minutes before judging, the accident apparently robbing him of 1st honours.

Anateurs.—Mr. A. T. TATE, Leatherhead, won for eighteen bunches, distinct: Moss cristata, Mochata nivea, W. A. Richardson, and Allister Steele Gray, were especially good.

In an extra class for twelve, Rev. J. H. PRINCE, Havering, was successful; Carmine Pillar, Jeanne's Pride, W. A. Richardson, Paul's Single White, and York and Lancaster, being his best.

Mr. F. W. CAMPION, Reigate, won with a splendid stand of six trusses; W. Allen Richardson, Laurette Messing (extra), B. Job, Marnet, and Reine de Heide Wurtemberg, all being good. Miss G. CAMPION, Ryde, followed closely.

An extra (open) class for nine bunches of single-flowered varieties found Messrs. COOLING & SONS, Bath, just ahead of G. PAUL & SONS, Cheshunt.

NEW ROSES.

These were few. Messrs. G. PAUL & SONS' Rev. Allan Charles is a most distinct colour among H.P.'s, reminding one of a very bright M. Niel.

Purity, from Messrs. COOLING & SONS, Bath, is decidedly a good pillar Rose, free in every respect; a pure white, and when fully expanded, of much the same size and form as Souvenir de Paul Neyron.

Unfortunately it was a bit-tensid day, and when our report left at 2.15, rain was falling smartly.

SILVER MEDAL BLOOMS.

Nurserymen.—Messrs. PRION & SONS, Colchester, for Lady Mary Fitzwilliam; and Mr. G. PRINCE, Oxford, for Contesse de Nadaille.

Anateurs.—Mr. A. TATE, Leatherhead, for H.P. Mrs. J. Laing, and for Tea Madame de Wattoville.

THE VICTORIAN ERA.

Horticultural Show at the Crystal Palace.

JUNE 23, 24.—The only effort made to hold a horticultural exhibition during the Queen's commemorative festivities, that should in some measure illustrate the phenomenal advance that has been made in the development or improvement of various plants during the Victorian Era, must be admitted to be a comparative failure. The Crystal Palace Company a few months ago drew up a schedule containing classes for plants that have been introduced or wonderfully improved since the accession of the Queen, and, as was remarked in these columns recently, it offered facilities for the exhibition of features quite novel in present-day flower shows, but the show has been held, and has proved disappointing. The Palms that were expected to form an interesting feature, did not turn up, the Conifers that are so seldom seen exhibited in competition, were to say the least not equal to expectation. There was little competition even in the classes that were represented, and more than that, the class for a miscellaneous group of plants of species "introduced during Her Majesty's Reign" did not have a single entry. The Carnations from Mr. MARTIN R. SMITH, the Begonias from Mr. WARE, the Caladiums from Messrs. FERD, &c., were good, but such plants as Gloxinias, Crotons, Ferns, &c., were represented by exhibits not by any means entitled to be described as first class. The chief reason for this was probably the inconviction day upon which the show was held. This circumstance was foreseen, we believe, but other fixtures at the Palace prevented another day being selected. Possibly, also, the catastrophe that befell exhibits at York may have had some influence, as well as the fact that the Richmond Show was held upon the same day.

Mr. THOS. S. WARE, Halo Farm Nurseries, Tottenham, obtained 1st prize for a group of BEGONIAS. The group, which had to be staged upon a space not exceeding 300 square feet, faced all ways, with paths around it. There was a large pyramidical dome in the centre, and a smaller one at each corner. The central cones contained double and single-flowered varieties, the smaller ones in each case for most part exhibiting the charms of a particular variety. Thus one small cone was composed of plants bearing a rose-fingert double Begonia, named Sunset Pope, a very pretty one indeed. On another mound was a fine crimson double, named Mr. Robert Lawford; on another, an excellent new Camellia-flowered white double named Jubilee Queen. The interspaces between the cones were prettily furnished with more Begonias, with no names attached, but of a very desirable strain, and a proportionate amount of suitable scenery.

CALADIUMS at this stage of the Victorian era were probably more popular than any other foliage plant; but it was left to Messrs. FEED & SONS, of Roupell Park Nurseries, West Norwood, to exhibit the splendour of the varieties of the present day—their indescribable colourings and markings, and the desirable dwarf habit many of them possess. Messrs. FEED & SONS exhibit a new isolated circular group, composed of bold, well-folaged plants, each of stout habit, beautifully coloured, and individually embedded in a ground of Ferns. As we have recently had occasion to particularise many of the best varieties, with reporting the Temple Show, it is unnecessary to insist on their beauty.

CAMPIONS were shown by two firms, who have commenced the cultivation of the plants on a large scale. Messrs. PAUL & SONS, Cheshunt, and H. CANNELL & SONS, Swanley. Unfortunately the group from Messrs. H. CANNELL & SONS was disqualified. This circumstance was probably the means of sending the 1st prize to the group from Messrs. PAUL & SONS, who were staged upon steps in a very strikingly facing the great organ. Messrs. PAUL & SONS probably of their own raising; and we also noted a variety with reddish-salmon-coloured flowers named Jubilee.

Messrs. CANNELL'S group contained a good number of closely-placed plants, bearing large, strong inflorescences, and illustrative of brilliantly-flowered varieties. A few more of the Queen's Caladiums and other varieties, exhibited in jars to face the group, resulted in the disqualification, but a solatium of a Silver Medal was awarded.

CROTONS were but poorly represented, nothing like they are usually exhibited at some provincial shows. There was one group, and it contained some large specimens of well-known varieties edged with smaller plants, but the whole was very disappointing. The plants that have been introduced by a nurseryman's collection. This may be said without depreciating the quality of the amateur's group from Mr. W. HOWE, jr. to HILARY TATE, Esq., Park Hill, Streatham Common. A 2nd prize was awarded.

CONTESSES were shown for competition by Mr. Jno. B. Cox, West Wickham and Clevedon. This exhibit was criticised

of a large number of plants, but they were small for the greater part, and disappointing in a class the 1st prize for which was £20. As the public could only see the collection from the face of it, many of the varieties at the back could be recognised only with difficulty. As a rule, they consisted of popular and well-known species, including the golden, variegated or slender habited varieties of some of them. A 3rd prize was awarded.

FERNS only obtained a 2nd prize in the class set apart for them. The exhibit was one from Mr. Howe, and it included specimens of Nephrolepis, Barceolites, Adiantum, and other ferns, Adiantum concinnum latum, C. Thoudii, Lomaria Blechnoides, Adiantum cucullatum, A. carolinense, Marattia fraxinea, and Adiantum Williamsii.

CONISTAS came from Messrs. J. FEED & SONS, who staged a nice group of plants upon a table, and gained a 1st prize.

Hardy ALPINE PLANTS from Mr. THOS. S. WARE, gained a 1st prize, and the exhibit represented a considerable variety of these diminutive but beautiful flowering plants. Some of the Veronica, Dianthus, Campanulas, and Arabis were among the most showy.

Hardy HERACODES PLANTS were shown by Mr. THOS. S. WARE and Messrs. WALLACE & Co., Kilmfield Gardens, Colchester. The 1st prize was awarded to Messrs. WALLACE for a collection very similar to their usual exhibits, including an excellent lot of Calochortus clavatus and Iris. The flowers were very choice, and if they did not represent hardy herbaceous plants, very fully; they capitally illustrated the bulbous section to which they belong. The new Eldorado type of Calochortus in endless variety are very beautiful. Rather stronger coloured perhaps than the common type, the flowers are similarly blotched, but the ground colouring is some shade of rose usually in place of white. Calochortus clavatus, a new very large yellow-flowered species, with purple anthers, is to be recommended. In addition to the Lilies and Irises, there were a few Phloxes, Ornithogalum, Gladiolus, greater Brodiaea, &c. Mr. S. WARE, whose group very greatly exceeded the space permitted, was awarded 2nd, for a miscellaneous collection of hardy herbaceous flowers, including some bulbous species; and Mr. Jno. R. Box was 3rd.

ORCHIDS were shown in two classes, by nurserymen and amateurs. In the former class, the 1st prize was awarded to the only exhibitor, Messrs. W. L. LEWIS & Co., 1, York Buildings, London, who staged a fine variety, with a few choice Cypripediums, Miltonias, &c. The amateurs' group of Orchids was a most tasteful one, and included considerable variety. Many of the Odontoglossum crispum varieties being of fine merit; Vanda cernicea, Cymbidium, Dendrobium, and Masdevallias, &c. were included.

PALMARIONTS, show and fancy, from Mr. TURNER, Royal Nurseries, Slough, included upwards of twenty well-named plants. A group of twelve Polyanthons from Mr. M. LARSEN, Becken Nursery, Enfield Highway, obtained a 3rd prize in another class.

ROSES as cut blooms in a collection of twenty-four, and as a group of plants, both exhibits from Mr. CUAS, TURNER, Royal Nurseries, Slough, were awarded 2nd prize in each instance.

NON-COMPETITIVE EXHIBITS.

One of the most important of these was the collection of CONIFERS from Messrs. J. YELT & SONS, Royal Exotic Nursery, Chelsea. Some of the plants were 6 or 7 feet high, excellent specimens, that had been lifted from the open ground and dropped into large shallow baskets. There were two magnificent plants of Abies procera argentea, exceedingly well coloured; also a pair of Taxus latifolia comensis, a golden form of much merit; Retinospora plumosa argentea and aurea, R. obtusa nana and aurea, R. squarrosa, R. filifera, Cedrus atlantica argentea, and C. a. aurea, Cupressus Lawsoniana albo-variegata, Abies excelsa inverta, a curious-looking drooping variety; A. Veitchii, a brachyphylla, Picea canadica, P. orientalis aurea, P. excelsa Rononiti, Tsuga Sieboldii, Thuja dolabrata, and other species; Taxus fastigiata aurea variegata, Cedrus Deodara aurea, and Pinus montana were some of the fine things shown in Messrs. Yelton's group, which was deservedly awarded a Gold Medal.

CARNATIONS took MARTIN R. SMITH, Esq., The Hayes (gr. Mr. Bick), from the form of an exceptionally large group of plants, all of which were splendid examples of culture, and bore a profusion of bloom. The variety of colour in the flowers, too, was very great; and when it is stated that the whole of the varieties exhibited had been raised in Mr. SMITH'S garden, the credit due to this energetic and successful amateur may be estimated. A Gold Medal was awarded.

"LIVE-STOCK HOBBIES."—The appearance of this journal weekly, and procurable for a penny only, should be hailed with pleasure by all who keep a pet animal. The publication deserves notice as dealing not merely with dogs, cats, and the more usual household animals, but with the treatment of out-of-the-way pets, such as newts, lizards, &c. It is certainly an imperative duty to treat captive creatures properly, and any magazine which helps to this result is deserving of support.

IMPROVEMENT OF PASTURES.

IN connection with the Leicestershire Chamber of Agriculture, Mr. J. J. Willis, of the Rothamsted Agricultural Station, delivered a lecture in the Council Room, Leicester, recently, on the important subject of "Improvement of Pastures."

After a few introductory remarks, Mr. Willis said the Rothamsted grass experiments were commenced in 1856, about 7 acres were selected and divided into twenty-four plots, to each of which a different manure was applied. The flora of the plots at the beginning was fairly uniform over the whole area, but by the application of various manures the flora of the plots has now become entirely changed.

The quantity of hay obtained has varied on each plot very considerably according to season; but taking the average of the whole period of forty years, the plot to which no manure had been applied has given about one ton of produce per acre per annum; while

Another very important lesson to be gathered from the Rothamsted experiments is, that a bad pasture, or one that has been wrongly treated, may be brought back to its original goodness, and even improved, by proper manurial applications.

In considering the improvement of pastures, the first necessity to which attention was directed was that of drainage; an imperfectly-drained field can never be converted into a first-class pasture. Coarse grasses, sedges, and useless weeds will always make up the bulk of such a pasture. The herbage will be sour and of little feeding value, because it will be badly matured. Butter made from a badly-drained pasture will be inferior in quality, and will quickly sour. A considerable improvement in a pasture may frequently be effected by liming, chalking, or giving a dressing of marl or road scrapings.

Reference was made to some experiments at Rothamsted on the application of lime and chalk to pasture. With lime or chalk alone, the produce of

10 or perhaps 11 inches across, and the standards by measurement are 7 inches long and 5 inches wide. The colour of this form may be described as creamy-white, and it struck one as not having the usual cast of grey-lilac, and as being without the usual large display of dots. Iris Gatesii was illustrated in the *Gardeners' Chronicle* of July 5, 1890, and is known as the finest of the *Oenoclytus*, or perhaps any other section of the genus; but here we find a flower far surpassing any former promise made by the species.

Another choice Iris, and a novelty of which we had not before heard, is *I. Mancoi*, of Florida, considered, we believe, by Mr. Gerard, as a variety of *I. hexagona*. From this, however, it is apparently quite distinct, differing at first sight in the broader leaves, which are not so tall and erect; and in the flowers, which are narrower parts, and are produced, according to the specimen, low down and near the ground. It is hardier, we learnt, than *I. hexagona*, but it does not seem to be so ornamental.

Iris es are not the only feature of this garden. The display of *Eremurus robustus*, though now fairly over, must lately have been very fine. *Incarvillea Delavayi* is in great perfection, and is noteworthy as one of the finest of hardy plants, several stems in this instance rising, perhaps, to a height of 18 inches, and bearing numerous splendid *Bigonia*-like flowers of bright russet-red colour. A very charming feature we found in the grassy and flowery chalk banks, which are beautiful in the way of the "wild garden." They are planted with a variety of subjects suitable for such a position; among which the *Linum*, white *Dianthus*, and red *Valerian* are now dominant, as if, indeed, for the *Jubilee* week. It is a hard thing to kick against the pricks of sweet mother Nature, but the result, as here, is often delightful when art goes with her, hand in hand. *R. Irwin Lyon*.

FIG. 165.—YANDA MISS JOAQUIM, OBTAINED BY CROSSING V. TERES AND V. HOOKERIANA.

(See Report of Royal Horticultural Society, in our issue for June 19, 1897.)

the plot the most heavily manured has given about 4 tons per acre per annum.

The number of plants found in the mixed herbage on the unmanured-plot is between fifty and sixty, while on the highest manured-plot the number has decreased to fifteen, and here 99 per cent. of the crop is composed of a few of the coarsest grasses.

None of these plots are recommended for exact imitation, but they teach many valuable lessons. In the first place, these experiments show, that however good a pasture may be, it is capable of being entirely spoiled by mismanagement. In the second place, the fact is brought out that it is not the description of seed sown which determines the character of a pasture, but its manurial or other treatment. For example, if the crop is cut for hay, the effect will be one way; while if the herbage is left by stock, the influence will be another. Acain, mineral manures, such as basic slag, kainit salt, potash, bone meal, and superphosphate will produce one effect; while nitrogenous and forcing manures, such as nitrate of soda, ammonia-salts, or guano, will produce another effect entirely. A combination of these manures or farmyard dung will yield a different result from either of the former.

hay was raised one-half more; and with lime and chalk together, the produce was nearly doubled on certain plots. The quality of the herbage was also considerably improved, Clovers and Vetchings were encouraged, so as to yield 47 per cent. of the whole crop.

Reference was also made to the assimilation of the nitrogen of the atmosphere by the Clover family, and the improvement of the pasture thereby, with a corresponding increase of crop.

The most suitable manures for the encouragement of the Clovers, and the better description of grasses, was dealt with, the subject being illustrated by diagrams.

CHOICE IRISES.

THERE is always something good to be seen in Professor Foster's garden; and although it is now late for the best of the genus which makes it famous, there is in flower perhaps the finest example of *I. Gatesii* ever seen. The stem is about 2 feet high, and it bears a flower which is quite one of the largest seen in a garden, and certainly the largest that could be grown out-of-doors. It could not be less than

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1 continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

The Districts indicated by number in the first column are the following:—
 0, Scotland; N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties, & England, including London, S.; Principal Grasses, &c., Districts—5, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending June 19, is furnished from the Meteorological Office:—

"The weather during this period was very unsettled and rainy generally, although the earlier days had been fine and bright over England. The rainfall over Ireland, the north of England, and the greater part of Scotland was very heavy.

"The temperature was high at the commencement of the week, the absolute maximum readings ranging from 84° in the 'Midland Counties' and 'England, S.' and from between 80° and 82° in the other 'English districts, to 68° in Scotland, N., and 61° in 'Ireland, S.W.' Later on the daily maximums were very low for the time of year, especially in the north and north-east. The lowest of the minima, which were registered either on the 17th or 19th, ranged from 37° in 'Scotland, N.,' 38° in 'Scotland, E.,' and 39° in 'Ireland, N.,' to 45° in 'England, S.W.' and to 50° in the 'Channel Islands.' The average for the week was considerably below the mean value for the time of year over Ireland and Scotland, and slightly below it in the 'Midland Counties' and 'England, N.W.:' in most of the other English districts the weekly value just equalled the normal, but in 'England, S.' it was a little above it.

"The rainfall exceeded the mean in all districts excepting 'England, S.:' in the north and west the fall was unusually heavy, being about five times the mean in 'Scotland, N. and W.:' four times in 'Ireland, N.:' and three times in 'England, N.E.:' and 'Ireland, S.:' The highest average rainfall at individual stations was 4.25 ins. at Glasgow, and 3.85 ins. at Ardrossan, at the latter station 3 inches fell in about twenty hours during the middle of the week.

"The bright sunshine exceeded the mean in most parts of England, but was less elsewhere. The percentage of the possible duration ranged from 57 in 'England, S.:' and the 'Channel Islands,' 56 in 'England, S.W.:' and 55 in 'Ireland, E.:' to 24 in 'Ireland, N.:' and 17 in 'Scotland, E.:'

MARKETS.

COVENT GARDEN, JUNE 24.

[We cannot accept any responsibility for the subsequent reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the supplies, the state of the markets, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

PLANTS IN POTTS.—AVERAGE WHOLESALE PRICES.

Table with 2 columns: Plant name and Price. Includes Adiantum, Aspidistra, Calceolarias, Crassula, Dracaena, Evergreen shrubs, Ferns, Fuchsia, Begonia plants, and Bedding plants.

FRUIT.—AVERAGE WHOLESALE PRICES.

Table with 2 columns: Fruit name and Price. Includes Cherries, Grapes, Pineapples, Strawberries, and Melons.

VEGETABLES.—AVERAGE WHOLESALE PRICES.

Table with 2 columns: Vegetable name and Price. Includes Artichokes, Asparagus, Beans, Cabbages, Carrots, Cauliflowers, Cucumbers, Eggplants, and Mushrooms.

POTATOS.

With a fairly brisk trade for new Potatoes, prices rule as follows:—Jersey Whites and Kidneys, 110 to 115; St. M. 30 and Gibraltar, 105 to 110; Kent, Banquet, Mammoth, 85 to 90; others, 75 to 85; John Bath, Wellington Street, Covent Garden.

OUT FLOWERS.—AVERAGE WHOLESALE PRICES.

Table with 2 columns: Flower name and Price. Includes Arums, Bouvardias, Carnations, Gladioli, and various other flowers.

ORCHID-BLOOM IN VARIETY.

GARDENING APPOINTMENTS.

MR. O. GRIGG, as Head Gardener to the Earl of ASHBURNHAM, Ashburnham Place, BATTLE, SUSSEX. MR. F. W. RUSSELL, for the past ten years Head Gardener to E. T. DONAT, Esq., Woodgreen Park, Chesnut, as Head Gardener and Inlet of H. TROWER, Esq., Tewin Water Park, Welby, Lincs. MR. J. H. WALKER, late of Buckden Towers, as Gardener to J. LISTON, Esq., Stirlow House, Buckdon Huntingdon.

ENQUIRY.

CROZY CANNAS.—Will some reader communicate the true and complete pedigree of the Crozy Cannas, i.e., of Madame Crozy? Burlington.

CARNATION "GRASS" SPOTTED: Carnation: The plant is affected with a species of fungus, Helminthosporium echinulatum. There is no known cure, and you should pull up the plants and burn them.

CORRECTION.—The three varieties of Carnations, Cecilia, Barras, and Helmasman that received Awards of Merit at the last meeting of the Royal Horticultural Society, were exhibited by Mr. Blyck, gr. to Martin R. Smith, Esq., and not by Mr. Turner, as was stated in our report.—HARDY TREES AND SHRUBS OF THE VICTORIAN ERA.—Allow me to correct a slight error made by your correspondent. He is wrong in attributing the introduction of Berberis stenophylla, see p. 399, to our firm. I think you will find it was sent out by Messrs. Fisher & Holmes of Sheffield. Cytisomeria elegans was introduced by my brother John in 1862, not 1867, Harry J. Veitch.

GRAPES WITH SPOTTING ON THEM: J. L. The berries are affected with the fungus Gloeosporium heliophilum. Cut out all affected berries, and burn them forthwith. There is no known cure.

LILIA TENEBRISA: G. G. The failure to expand its flowers after removal from the stove is probably due to the lower temperature of the house, to the plant carrying too many flowers, and perhaps to the amount of water afforded not being appreciably lessened. A plant twelve months rejected could scarcely fail to be established, and the fact that it showed flower freely is a proof that it had taken to the potting materials.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—A. P. H. Staphylea pinnata.—E. H. C. Cytisoid umbilicus.—H. V. The specimen is quite withered, and has no flowers. It is most probably Saenahiera coronopus, Wart Cross.—Hurst & Son. Probably Linaria vulgaris, Todd Flax, but there are no flowers.—Kent. Phlox-ulmaria crenatus and Cytisoid chrysantha; Euphorbia, next week.—T. T. Nematum. Trichophylla Galeottiana.—H. M. E. Aërides Houlettianum, Rosa microphylla, and Campanula paella.—Box without letter. I, Cornus sibirica Spach; 2, Robinia pseudo-acacia variegata; 3, Azara microphylla; Weigela hortensis variegata; 5, Cotoneaster Simonsii; 6, Koeleria paniculata.

CONTINUED LARGE INCREASE in the CIRCULATION OF THE "GARDENERS' CHRONICLE." IMPORTANT TO ADVERTISERS.—The Publisher has the satisfaction of announcing that the circulation of the "Gardeners' Chronicle" has, since the reduction in the price of the paper, increased to the extent of more than 90 per cent., and that it continues to increase weekly. Advertisers are reminded that the "Chronicle" circulates among COUNTRY GENTLEMEN, and ALL CLASSES of GARDENERS and GARDEN-LOVERS at home, that it has a specially large FOREIGN and COLONIAL CIRCULATION, and that it is preserved for reference in all the principal Libraries.

FRUIT AND VEGETABLES.

GROSWOOD: June 23.—The following are the averages of the prices current here during the past week:—Apples, 6d. per bush; Bonnets, Currants, 8d. doz.; Scotch, 1s. 6d. doz.; Grapes, home, 2s. to 3s. doz. Vegetables: Parsnips, French, white, 1s. to 1s. 2d. per bunch; do, white, 4s. 6d. to 6s. per dozen bunches; do, Swedes, 2s. to 2s. 6d. per cwt.; do, French, new, 1s. to 1s. 2d. per bunch; Carrots, French, new, 1s. to 1s. 2d. per bunch; do, Dutch, 1s. 9d. to 2s. 6d. per dozen bunches; Cabbages, 8d. to 1s. per dozen; do, Dublin, 8d. to 9d. doz.; Cauliflowers, Scotch, 1s. to 1s. 6d. per bunch; do, Dublin, 2s. 6d. to 3s. doz.; Parsnips, 4s. 6d. to 5s. per cwt.; Herbs, assorted, 1d. to 2d. per bunch; Mint, green, 6d. per bunch; Onions, Globe, 7s. per cwt.; Parsley, 5s. per stone; Potatoes, best, 6d. doz.; do, Paris, 3d. per lb.; Broccoli, 2s. 6d. to 3s. 6d. per dozen; Beans, French, 7d. to 8d. per bush; Market, Broadwings, French, 1s. 6d. to 1s. 9d. per bunch; do, English, 2s. to 2s. 6d. doz.; Cucumbers, 4s. to 5s. per dozen; Lettuce, round, 1s. to 1s. 2d. per dozen; do, French, 1s. to 1s. 6d. doz.; do, Cos, 3s. 6d. to 4s. doz.; Radishes, 2d. to 3d. per dozen bunches; Horse-radish, 2s. 3d. to 2s. 6d. per bunch; French Beans, 6d. to 9d. per peck; Mangetout, 6d. to 9d. per bush; Beet-root, 7d. to 8d. per peck; Cress, 6d. to 9d. per dozen; Endive, 1s. 6d. to 2s. per dozen; Spinach, 2s. to 3s. per stone; Blubruh, 2s. 3d. to 2s. 6d. per cwt.

LIVERPOOL: June 23.—Average of the prices current at the undermentioned markets:—St. John's: Potatoes, 1s. per peck; do, new, 1d. to 2d. per lb.; Pars, 1s. 6d. per peck; Asparagus, 1s. 6d. to 2s. per 100; Cucumbers, 7d. to 6d. each; Apricots, 1s. per dozen; Gooseberries, 5d. per lb.; Pines, English, 4s. to 4s. 6d. each; Cherries, 6d. to 8d. per bush; Strawberries, 6d. to 1s. doz.; Mushrooms, 1s. doz.; Birkenhead: Potatoes 8d. to 10d. per peck; do, new, 1d. to 1 1/2d. per lb.; Pars, 1s. 2d. to 1s. 4d. per peck; Asparagus, 2s. to 2s. 6d. per 100; Cucumbers, 2d. to 6d. each; Apricots, 1s. per dozen; Gooseberries, 2d. to 3d. per lb.; Currants, 1ed. 6d. to 8d. per lb.; do, black, 8d. per doz.; Cherries, 6d. to 8d. doz.; Strawberries, 8d. to 1s. doz.; Mushrooms, 1s. doz. to 1s. doz. North: Potatoes per cwt, Jersey, 8s. to 8s. 6d.; Gints, 2s. to 2s. 4d.; Main Crop, 2s. 8d. to 3s.; Champignons, 2s. to 2s. 4d.; Brues, 2s. 4d. to 2s. 9d.; Turnips, 1s. to 1s. 6d. per 12 bunches; Onions, foreign, 6d. 6d. to 7s. 3d. per cwt.; Parsley, 8d. to 10d. per 12 bunches; Lettuce, 6d. to 1s. per dozen; Cucumbers, 2s. to 3s. doz.; Cabbages, 10d. to 1s. 10d. doz.; Pars, 2s. 10d. to 3s. per bush.

CORN.

AVERAGE PRICES OF BRITISH CORN (per imperial qr.), for the week ending June 19, and for the corresponding period of 1896, together with the difference in the quotations. These figures are based on the official Weekly Return:—

Table with 4 columns: Description, 1896, 1897, Difference. Includes Wheat, Oats, and Barley.

Obituary.

JAMES MENZIES.—Allow me space wherein to record the death of my dear old friend, Mr. James Menzies (age 71), who died at South Lytchet, near Poole, Dorset, where he had been gardener for many years; and who was held in great respect by all who knew him. He was one of the now few remaining pupils of the late Charles Mackintosh of Claremont, and Dalkeith Palace Gardens. P. D.
